LIST OF FULL-PAGE PLATES.

Vol. III.

quired to be removed in sharpening. *a b* show the most ordinary forms; each is ground transversely, the former on a wheel of 12, and the latter on one of 4 inches diameter.

In some cases, as *c*, the blade is ground longitudinally, giving it a thinner edge; these are termed *rattlers* by the Sheffield cutlers in consequence of their tendency to vibrate when shaving a heavy beard. Others (*d*) are ground in both ways. These are called *half-rattlers*. *e* is formed by setting the blade in a backing. *f* has a brass frame or guard to prevent persons whose hands are tremulous from accidentally cutting themselves. It is called a guard-razor.

Ra'zor-pa'per. Smooth, unsized paper, one side of which is treated with a composition of crocus and flour-emery in powder. It is used to wipe the razor, and is intended as a substitute for the strop.

Ra'zor-strop. An implement for sharpening razors or other thin-edged tools. It usually has a handle and a case for receiving it when not in use. Some kinds have but two abrading surfaces, — that to which the razor is first applied, consisting of leather thinly coated with fine emery-powder; and the second, by which keenness of edge is finally imparted, of leather alone. Others have four sides, coated respectively with a hard composition and with leather of different degrees of fineness, to which the razor is successively applied.

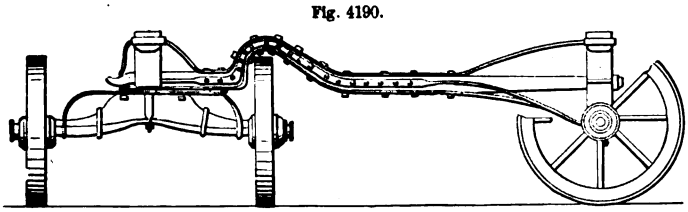
Barbers keep their razors in order after being once *set* by rubbing on a leathern strap suspended by one end, and held by the other.

Reach. 1. (*Vehicle.*) A pole connecting the rear axle to the *bolster* of a road-wagon. A *coupling-pole.*

Some modern carriages have none, the *bed* or body performing that duty.

A reach for a certain description of city wagon is shown in Fig. 4190. It is arched in front, so that the fore wheels may pass under it, enabling the vehicle to be turned in a shorter space. The circular sway-bar is extended, so as to support the reach when turned in any position.

Fig. 4190.

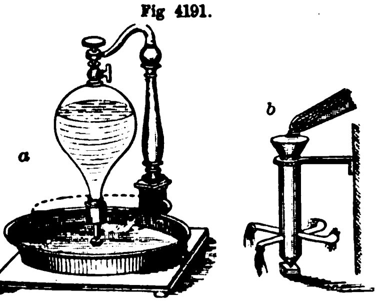


Wagon-Reach.

2. (*Hydraulic Engineering.*) That portion of a canal between two locks having a uniform level. Also called a *pond.* *Locks, lifts, inclines, slides,* or *sluices* connect *reaches* of different levels.

Re-ac'tion Wa'ter-wheel. A wheel to which a rotary motion is imparted by the action of streams of water issuing tangentially from its sides under the pressure of a head of water entering it from above. The principle, which is that of recoil, is embodied in *Barker's mill* and in the turbine. It differs in nothing from Hero's Æolipile, except that in the latter steam under pressure is the motor. Reaction water-wheels are made single or double, the latter having two on a single shaft. One form has radial buckets on which the water confined in a vertical chute impinges (see FLUTTER-WHEEL) and then escapes at the ends through wheels on the reaction principle. This form has a horizontal axis. See also TURBINE.

Fig 4191.



Reaction Water-Wheels.

The motive power exerted by liquids escaping horizontally is illustrated by a device called the hydraulic tourniquet (Fig. 4191), consisting of a vessel pivoted at its upper and lower extremities and having two pipes at bottom whose ends are bent in opposite directions. On filling the vessel with water, it escapes through these tubes, causing the vessel to revolve on its axis.

Perley and Pattee's saw-mill, at the Chaudière Falls, Ottawa River, Canada, has 6 gang-saws, each driven by a Rowe reaction-wheel, 5 feet in diameter, 400 inches sectional area of discharge. The head is 14 feet, and the power of each is about 70 horses.

Read'ing-glass. A large magnifying lens, used to assist in reading, etc.

Read'y Reck'on-er. A table or an instrument for making simple calculations, as the amount of wages due a workman for a given time, etc.

Re'al Ra'di-us. (*Gearing.*) The radius of the circle touching the crests of the teeth of a cog-wheel. The radius of the *pitch-circle* is called the *geometrical radius.*

Ream. A quantity of paper of any size containing 20 quires or 480 sheets. A common practice is now to count 500 sheets to the ream.

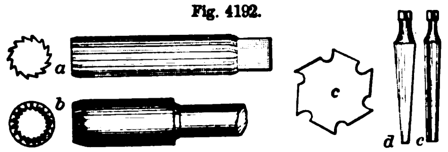
Ream'er. Sometimes, but incorrectly, written *rimmer.* A tool used to enlarge a hole and bring it to a shape the counterpart of the tool, whether cylindrical or tapering.

Broaches are *reamers,* being multiple-sided taper rods, whose angles cut the sides of the holes in which they are rotated. See BROACH.

The reamer is used in *truing* or rounding the holes made by a rock-drill.

As a machinist's tool (*a b*), it is fluted and slightly tapering; the blades being worked out of the solid metal by planing or milling on a machine. The flutes are then *backed off* like a *tap* to give a saliency to the cutting-edge.

Fig. 4192.

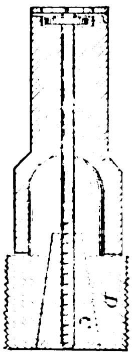


Reamers.

Instead of mere longitudinal fluting, the grooves in the tool may be made spiral, a right and a left hand, crossing obliquely so as to leave the surface in diamond-shaped portions. The flutings are then planed out and backed off, the result being a toothed reamer *c* of effective character.

The flat-sided reamers, such as *d e*, triangles, squares, and pentagons, are properly termed *broaches.*

Fig. 4193.



Expanding Tap and Reamer.

Tools to be driven through a hole are DRIFTS (which see).

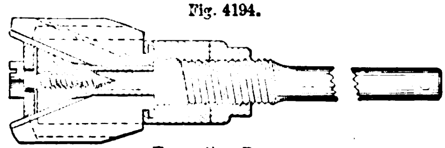
Half-round reamers are used in braces to enlarge holes in sheet-metal or small castings.

A revolving tool which cuts one size as it goes is a *drill*. A *reamer* is a cutting tool for enlarging a hole, and should enter the hole a piece before it begins to cut, so as to work steadily and straightly. This is not descriptive of the action of a drill, even though employed to enlarge an opening, as the *cored-out* hole in a casting.

In Fig. 4193, the cutters *D* are made in sections, having dovetail projections fitting grooves in the conical plug *C*, which is drawn upwardly so as to expand the tool radially to cut a dovetailed or undercut recess.

In Fig. 4194, the cutters are moved longitudinally by connection with a nut on the shank, and are

Fig. 4194.

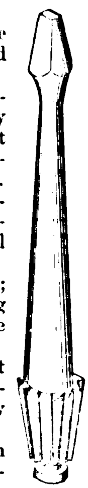


Expanding Reamer.

driven outward in their guide-slots by the conical end of the shank.

Ream'ing-bit. A broach of hardened steel having a taper form and angular cutting-edges. See BIT.

Fig. 4195.



Reaming-Bit.

Fig. 4195 has a guide at the end of the reamer to fit the hold to be enlarged and maintain the reamer in central position.

It is used for boring out truly or enlarging a hole commenced by a bit of ordinary construction. It has usually a shank about as large as the hole made by its cutting-face, to insure the straightness of the hole. Frequently, it has cutting-edges on its cylindrical portion, and acts to dress off irregularities and make a perfectly cylindrical opening.

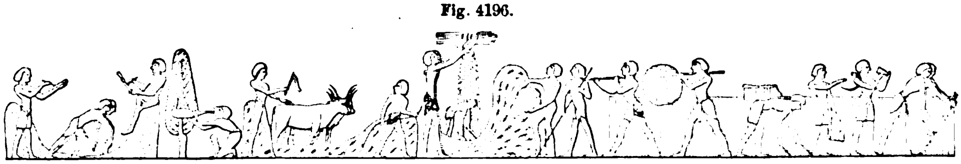
Reaming-bits are used in drilling metal; also in dressing to roundness and enlarging the size of holes bored by rock-drills. See REAMER.

Ream'ing-i'ron. (*Calking.*) A blunt chisel used for opening the seams between the planking of a ship preparatory to calking them with oakum.

Reap'er. A machine for cutting grain in the field. Wheat and barley were commonly cultivated in ancient Egypt. The former was cut in five months after sowing, the latter in four. The wheat was bearded, and generally cut below the ear, as in the annexed figure. It was cut with a smooth-edged or a toothed sickle. Both are represented in the tombs, and illustrations are given in this work under the caption SICKLE.

The whole series of harvesting and thrashing operations are shown in the accompanying illustration, which is from a tomb at Thebes of the probable date of 1490 B. C. The condition of the standing wheat

Fig. 4196.

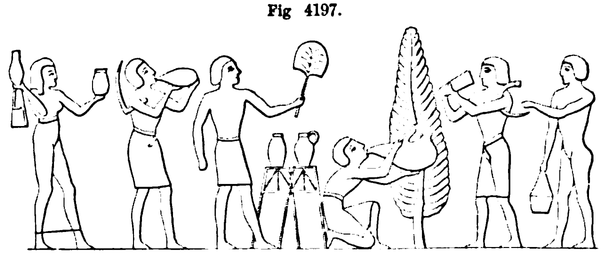


Harvest Scene (Thebes, 1490 B. C.).

shows that it was cut below the ear. Two men are working together, and, according to the then usual mode of representing such things, the motions of the parties are exactly simultaneous. The next man is taking a drink, sickle over his shoulder, in a manner quite customary among us, at this distance of thirty-three centuries. The man behind him is probably a gleaner, and urges him to hurry, as he too wants a drink. Next is shown a gleaner with his basket slung upon his back. He picks up the scattering ears and jerks them into his basket, like the chiffonier of Paris with his rags. We next see two men with a rope basket, carrying the ears from the field to the heap where they are tramped by cattle; a man tending with a whip and another throwing in the ears with a three-pronged fork. Then comes the winnowing; men with scoops lift the grain and chaff, throwing them up in the air, that the wind may blow away the chaff. By this time all parties are dry, and here is a kid-skin bottle hanging in the tree and a dusty Copt taking a pull at it. The next scene is at the grain-heap, where two scribes keep tally, — one, of the amount brought from the winnowing-floor, and the other of the amount sent to the granary.

Another harvest scene from the tombs is worth noticing in this connection, though the part selected is more specific in the refreshment line than in the work performed. In Egypt, as with us, the cool drink at the end of the row was not the least pleasant part of the day's experiences, but they could not rest in the shady fence-corner for lack of the trees and the fences. In the drawing, one tree lends its welcome shade, and to a limb is hung the kid-skin bottle at which the "fellah" is sucking. On the stand are two jars waited on by another "fellah" with a flabella, — call it a fly-brush. A thirsty man is devoting himself to a bottle, and a female comes up with a fresh supply. Another reaper, sickle on

Fig 4197.

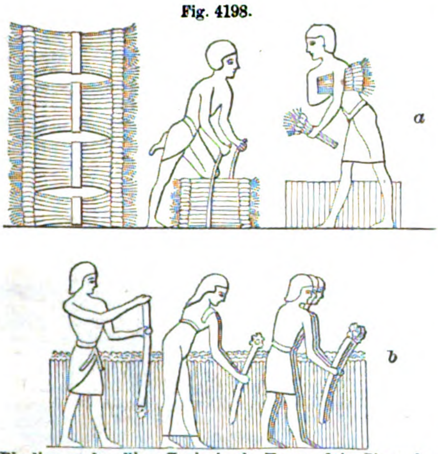


Harvest Scene (Time of Moses).

his shoulder, has a cup, and a poor, naked gleaner with his baskets puts in a claim for a drink.

While, as has been stated, it was common to reap the standing grain just below the ears, we also find two other modes, and they were also practiced in Gaul in the time of Pliny, 1,500 years afterward. One was to cut low and bind in sheaves, and the other to pull up by the roots. The figures represent these two scenes. The last-mentioned mode

Fig. 4198.



Binding and pulling Grain in the Egypt of the Pharaohs.

was practiced with the millet, doura, or whatever it was, — Wilkinson says *sorghum*. This was pulled, bound in sheaves, and carried to a place where the grain was stripped from the stalk by a man who drew it, a bunch at a time, over a comb or hackle. The operation is illustrated in a tomb at Eilethyas. The same instrument is now used for removing the capsules and seed from the flax-plant. It is called a *ripple*. See RIPPLE.

This *stripper* is probably like the *paddle-fork* mentioned by Pliny.

The references in the Bible to reaping and to the sickle wherewith it was cut are frequent, but add nothing to the perspicuity of the Egyptian paintings.

Coming down to early classic periods, so called, we find that the Greeks added nothing and the Romans little to the crude old mode of cutting grain by the curved sickle of Egypt.

Varro describes three modes of reaping as common in Italy: —

1. Cut low by a hook, the ears being afterward cut off and sent in baskets to the granary.
2. Cut off below the head by a toothed sickle, and the heads carried off in baskets.
3. Cut off at half the length of the straw.

In the first century of the Christian era we hear from Gaul. Says Pliny (A. D. 70): —

"The mode of getting in the harvest varies considerably. In the vast domains of the provinces of Gaul, a large hollow frame, armed with teeth and supported on two wheels, is driven through the standing grain, the beasts being yoked behind it (*in contrarium juncto*); the result being that the ears are torn off and fall within the frame. In other countries the stalks are cut with the sickle in the middle, and the ears are separated by means of paddle-forks."

The accompanying cut is a good restoration of the Gallic harvester of Pliny's day. Palladius wrote the *De re rustica* in the fourth century A. D., and gives a good description of this contrivance, which was similar to our "heading-machines," having a row of sharp teeth at the front edge, between which the straw passed, the head being torn off at the angle where the teeth met, and falling into the box of the machine.

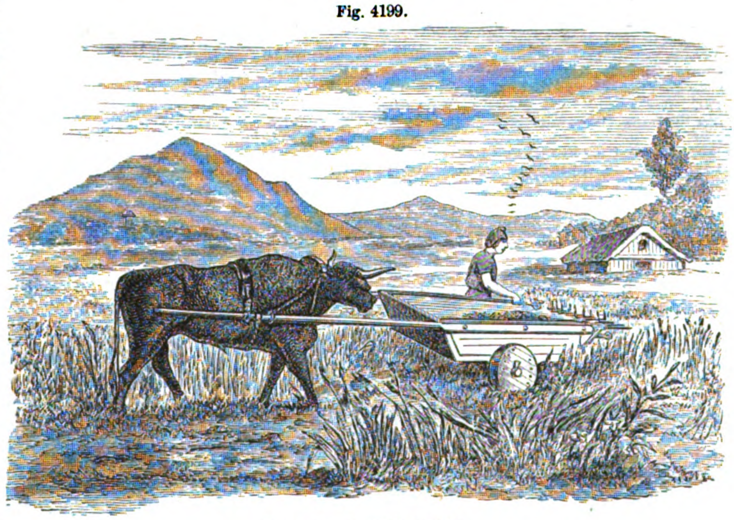
The description of Palladius is as follows: —

"In the plains of Gaul, they use this quick way of reaping, and without reapers cut large fields with an ox in one day. For this purpose a machine is made, carried upon two wheels; the square surface has boards erected at the side, which, sloping outward, make a wider space above; the board on the fore part is lower than the others; upon it there are a great many small teeth, wide set in a row, answering to the hight of the ears of the corn, and turned upward at the ends; on the back part of this machine two short shafts are fixed, like the poles of a litter; to these an ox is yoked, with his head to the machine, and the yoke and traces likewise turned the contrary way: he is well trained, and does not go faster than he is driven. When this machine is pushed through the standing corn, all the ears are comprehended by the teeth, and heaped up in the hollow part of it, being cut off from the straw, which is left behind; the driver setting it higher or lower, as he finds it necessary; and thus, by a few goings and returnings, the whole field is reaped. This machine does very well in plain and smooth fields, and in places where there is no necessity for feeding with straw."

After the lapse of fourteen centuries this machine has been reinvented, and is now used as a *header* for gathering clover-seed. See Figs. 1346, 2465.

The separation of the ears from the grain in the sheaf, mentioned above as being performed by paddle-forks, was probably done by drawing the bunches of grain over a paddle whose end

Fig. 4199.



Reaper in Gaul (*A. D.* 70).

was deeply notched and the teeth sharpened. The motion would be something like that of hackling hemp, and the ears would be speedily removed by this means. The object in saving the wheat, etc., in the head instead of in the sheaf, was probably to economize mow room. When stored in the ear instead of being first thrashed, it was as a precaution against weevil. Some have interpreted the passage of Pliny to refer to a comb of similar character, which caught the ears of the standing grain and tore them off or held them while they were beaten off by a paddle. This reminds one of the still simpler plan of the Northern Indians of Minnesota and Canada, who collect their store

of wild rice by leaning the heads over the side of the canoe and beating out the grain.

The above plans of heading the grain leave the straw in the field, which is a merit or otherwise, according to the circumstances of the case, — location, market, and mode of farming.

It would be absurd to overlook the different circumstances of Minnesota and Middlesex, which determine the question of economy. Pliny well says: —

"The diversity of the methods employed in harvesting mainly depends upon the extent of the crops and the price of labor."

The modern era of reaping-machines commences with the latter portion of the last century. The names of those who made the earliest attempts should be preserved, for in this, as in almost all similar cases, it was after a succession of earnest attempts by different parties that the desired success was achieved. Each great invention that has blessed us in modern times has been fought over. Witness steam-engines, steam navigation, photography, reaping-machines, and the electric telegraph. Most of those who worked at these problems added somewhat to the eventual success, and we may surely consider the matter with amiability and try to avoid acrimony.

The first modern machine resembled the old Gallic implement, in the respect that it stripped the head from the straw. The English machine of Pitt, in 1786, had a cylinder on which were rows of *combs* or *ripples*, which tore off the ears and discharged them into the box of the machine. For about two-score years attention was principally directed to revolving cutters or systems of revolving blades.

The motion of the cutting apparatus being derived from the rotary motion of the wheels supporting the implement, it naturally occurred to connect the axle or wheel with a rotary cutter, and later with an oscillating one, which had its analogues in the swing of the scythe and the reach of the sickle. A few attempts were made at a reciprocating knife, but they were scarcely heeded, and probably never made. The first reciprocating knife was in 1822.

As to the mode of attaching the horses, it was almost universally deemed necessary to hitch them behind the implement, which they pushed before them. Up to 1823 but four inventors hitched the team in front of the implement: one was in 1806; the others in 1820, 1822, 1823.

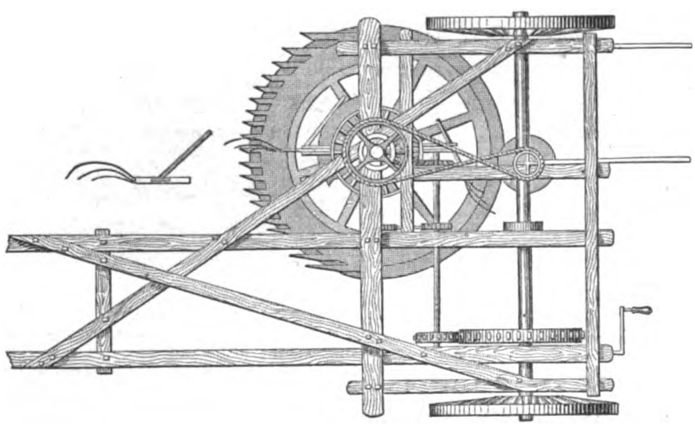
As soon as this idea did occur to the inventors, they made the horse walk alongside the swath, cut by the knives, constituting what is known as the *side cut*.

1799. Boyce had a vertical shaft with *six rotating scythes* beneath the frame of the implement. This was the first patented reaper.

1800. Meares tried to adopt *shears*.

1805. Plucknett introduced a *horizontal rotating circular blade*. He had a score of followers, and the first machine used

Fig. 4200.



Gladstone's Reaping-Machine (1806).

in this country, and patented by Bailey (Fig. 4200) in 1822, was of this character. Two machines by Smith, of Deanstone, in England, in 1811, and Scott, of Ormiston, in 1815, were made on this principle, were used practically, and had considerable local celebrity. Smith's machine was illustrated in "Hall's Dictionary," in 3 vols., folio, 1811.

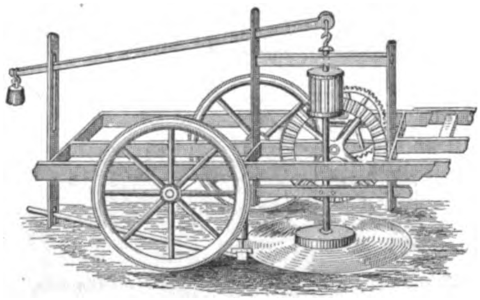
1806. Gladstone patented his *front-draft*, *side-cut*, revolving-knife machine. A segment *bar with fingers* gathered the grain and held the straw while the knife cut it, the fingers having the function of shear-blades. The forward draft was also adopted by Mann in 1820, and by Ogle, 1822, in his reciprocating cutter-bar machine.

1807. Salmon had a machine with some new features, — a row of *vibrating knives* over *stationary blades*; *fingers* to gather the grain to the cutters; a *rake*, suspended and reciprocating sideways to carry the grain off to the side. The machine was pushed ahead of the horse, or was propelled by hand. The machine of Bell, 1826, which was brought forward to confound the American exhibitors in 1851, has the same kind of cutters, and was also propelled.

1820. Mann had revolving rakes on a vertical axis, to sweep the standing grain past the cutter, and deliver it in a swath.

1822. Ogle shows the first *reciprocating knife-bar*. It is the

Fig. 4201.



Bailey's American Mowing-Machine (1822).

type of the successful machines, but was constructed so poorly that its merits never became apparent. It was drawn by horses in *advance*; the cutter-bar *projected at the side*, and it had a *reel* to gather the grain to the cutter. The machine had a *grain-platform*, which was tilted to drop the gavel. The *first dropper*.

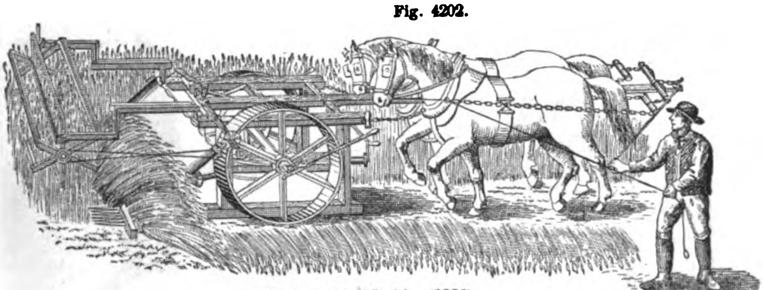
The machines previously mentioned are British. Fig. 4201 represents a self-sharpening mowing-machine, the first patented in the United States, in 1822. It has a circular revolving scythe on a vertical axis, rotated by gearing from main axle. The edge of the scythe in its revolutions passes under a whetstone fixed on an axis, and revolving with the scythe. The horse is in shafts, and *walks* in front of the left side of the machine, and always on the mowed ground after the first swath is cut. The grass, as it is cut, is first thrown by the progressive motion against a rise in the scythe-frame toward the center, and by the same motion is afterward thrown off in a regular row, following the center of the machine.

The machine of the Rev. Patrick Bell was tried at Powrie County, Forfar, Scotland, in 1828. It cut a swath of five feet with the power of a single horse, about an acre an hour. It was used again in 1829, and occasionally for a few years succeeding, then slept till 1851, when the World's Fair of 1851 in London introduced the American machines to the British public. The old Scotch machine was then brought from its limbo to challenge the American stranger.

The machine had a square frame on two wheels, which ran loose on the axle, except when clutched thereto to give motion to the cutters. The cutter-bar had fixed triangular cutters, between each of which was a movable vibrating cutter, which made a shear cut against the edges of the stationary cutter on each side. It had a reel with twelve vanes to press the grain toward the cutters, and cause it to fall upon a traveling apron which carried away the cut grain and deposited it at the side of the machine. The reel was driven by bevel-gearing.

The following machines are American: —

Fig. 4202.



Bell's Reaping-Machine (1826).

1846. Cook had a pendulous *rake swinging backwardly.*

1847. Ketchum had an endless chain cutter or *belt of knives.*

1847. Hussey's *slotted finger, open at top; knife of triangular sections.*

1848. Pease had a *grain-rake traveling sideways* beneath the platform, with slots for the fingers. Mann the same next year.

1848. Goble and Stuart had a revolving rake passing horizontally across the platform.

1849. Haines suspended the frame carrying the conveyor, reel, and cutter to the axles of the bearing-wheels, and hinged the frame to the tongue, so that it was capable of turning upon its bearings by means of a lever, to elevate and depress the cutter.

1825. Ten Eyk had a horizontal cylinder, with spiral knives cutting against straight edges. The same was shown by Budding in 1830.

1828. Samuel Lane, of Maine, combined the reaper and thrasher.

1831. Manning had a row of fingers and a reciprocating-knife. It was pushed in front of the horse.

1833. Schnebly had a horizontal endless apron traveling intermittingly, and delivering its gavel at the side.

1833. Hussey, of Maryland, made the first valuable harvester. It was patented as a mower. It had *open fingers*, the knife consisting of triangular sections reciprocating in the space, cutting shearwise against the guards. It was *front draft*, *side cut*, and had a platform. The open-top slotted finger was patented by Hussey in 1847. The cutter-bar was on a hinged frame. The raker rode on the machine.

1834. McCormick, of Virginia, patented his reaper, which, with various improvements, in 1845 and 1847 received a Council medal at the London World's Fair in 1851. This machine had a sickle-edged sectional knife, reciprocated by crank and pitman by gear connection to the drive-wheel, on which the frame rested. Spear-shaped fingers gathered the grain, which was laid over to the cutter by a revolving-reel. A *divider* was used on each end of the platform. The driver and raker had seats on the machine. The gearing and crank were placed forward of the driving-wheel.

1835. Randall had a *pair of knife-bars* reciprocating past each other. Wray, 1852, had the same.

1836. Briggs and Carpenter combined the reaper and thrasher. Moore and Haskell, the same year. Ridley, in Australia, seven years afterward, did the same, and supposed himself to be the first inventor.

Hazard Knowles, the machinist of the Washington Patent Office, invented in 1837 a reaping-machine having a scalloped reciprocating cutter; the cutting apparatus jointed to a double arm, the opposite end of which was in turn jointed to the main frame, coincident with the axis of the crank-shaft; both supporting-wheels were drivers for the cutters. It was a front-cut machine, and had a lever to raise the cutting-bar to clear stumps and other obstructions. A machine was constructed in 1838, and in 1839 was purchased by Joel Lupton, who rode upon the machine along the turnpike to his home, near Winchester, Va. The machine was used occasionally during a few of the following years, but was soon laid aside, owing to a fear of the neighbors that it would disturb the relations of labor. It was afterward purchased by one of the large firms of reaping-machine makers, who became involved in the tedious and expensive litigation which ensued when the reaper became an important article of manufacture and trade. This machine is principally curious in its anticipation of so many of the important features of the more useful machines. Like Bell's machine in its history, though far superior to the Scotch machine in mechanical structure and adaptedness, it was a conception embodied in a single machine, and became an abandoned experiment, to be brought forward when the inventions and contests of others gave it an importance. It was a machine of great possibilities, but its inventor failed to assert his rights. His position in the Patent Office prevented his becoming a patentee, and he preferred to retain his salary to embarking in the business of making machines of so novel a character. About 1863 the machine was brought forward in a patent suit. It may be presumed that it formed but another instance of the rule, that a single machine made and practically hidden away shall not be allowed to defeat a patent when a subsequent inventor has showed due diligence. It also indicates that the patent is a *quid pro quo*, an exclusive right in return for an invention adequately described on record.

1838. Wheeler had a machine with a revolving endless apron to deposit grain in a box with a sliding bottom, by which it was deposited in gavels. A *dropper.*

1840. Lamb. A platform to receive the gavels and carry the *binder*. The first hand-binder.

1841. Churchill thrashed out the grain, the heads of grain being pushed into the thrasher-cylinder.

1842. Reed discharged the grain from the bed by rake-fingers projecting through slots in platform.

In 1849, Jonathan Haines, of Illinois, invented the "header," which is the principal machine on the Pacific coast.

1849. Purviance made the platform removable, to convert the reaper into a mower.

1849. Platt's self-acting *rake sweeping over quadrantal platform*. Same feature in Palmer and Williams's and in Seymour's, 1851.

1850. Adkins's cutter-bar on *hinged frame.*

1850. Knowles and Bevington's side *dropper.*

1850. Heath's *binder*, with a reciprocating rake beneath the platform.

1851. Watson's automatic *binder.*

1851. Miller's *backwardly reciprocating rake.*

1851. Allen geared the operative parts from both wheels, to distribute the driving-power.

1852. Atkins had a rake rigged on a vertical post. It had a jointed arm which swept across the curved platform and gathered the gavel against a shield; the post, rake, and shield then turned 90° on an axis, the rake was raised, and the gavel dropped in rear of the driving apparatus.

This list is but a commencement, but brings us to a period when things became lively in this line. Since this period nearly 8,000 patents have been granted in the United States for harvesters and attachments therefor.

In the summer of 1855, at a competitive trial of reapers about 40 miles from Paris, France, three machines were exhibited, from America, England, and Algiers. The following was the result in a field of oats: —

The American machine cut an acre in.....22 minutes.
The English machine cut an acre in......66 minutes.
The Algerian machine cut an acre in......72 minutes.

In 1855, Jonathan Haines patented a machine in which the finger-bar extended across the rear end of the main frame, and was connected at each side with the front end of said frame by rods jointed at one end to the frame, and at the other to the finger-bar. The inner of these rods was a drag-bar to advance the cutting apparatus. The outer was a brace to maintain its position at right angles to the line of advance. It was supported laterally by a brace jointed at one end to the end of the finger-bar, and at the other end to the main frame at or near the axis of the crank-shaft.

In the Ball machine, shortly afterward, the drag-bar was joined rigidly to the finger-bar, and thus united drag-bar and brace in itself. The lateral brace was the same.

1856. The combined rake and reel of the "Dorsey" machine sweeping in a general horizontal direction across the quadrantal platform.

1857. Crook introduced an arrangement of driving-gears of unequal size to be used separately for changing the rapidity of vibration of the cutters.

1860. The Henderson rake, or what is known as the "Wood" machine, having a chain below the platform which carries the rake in a curved path.

1861. The Sieberling "dropper," which is a slatted platform that vibrates to discharge the gavel.

1861. Dutton inclosed the gearing in a metallic case, forming a part of the main frame.

Plate XLVI. shows three forms of the Whiteley "Champion" harvester of Springfield, Ohio. The upper figure is the mowing-machine; below it is the reaping-machine, with *dropping* arrangement, which deposits the gavel behind the cutter-bar; the lower figure is the self-raking reaper.

The reaping and automatic binding-machine of S. D. Locke, of Hoosick Falls, N. Y., made by Walter A. Wood of that place, and shown in Plate LI., is believed to have overcome the difficulties of the

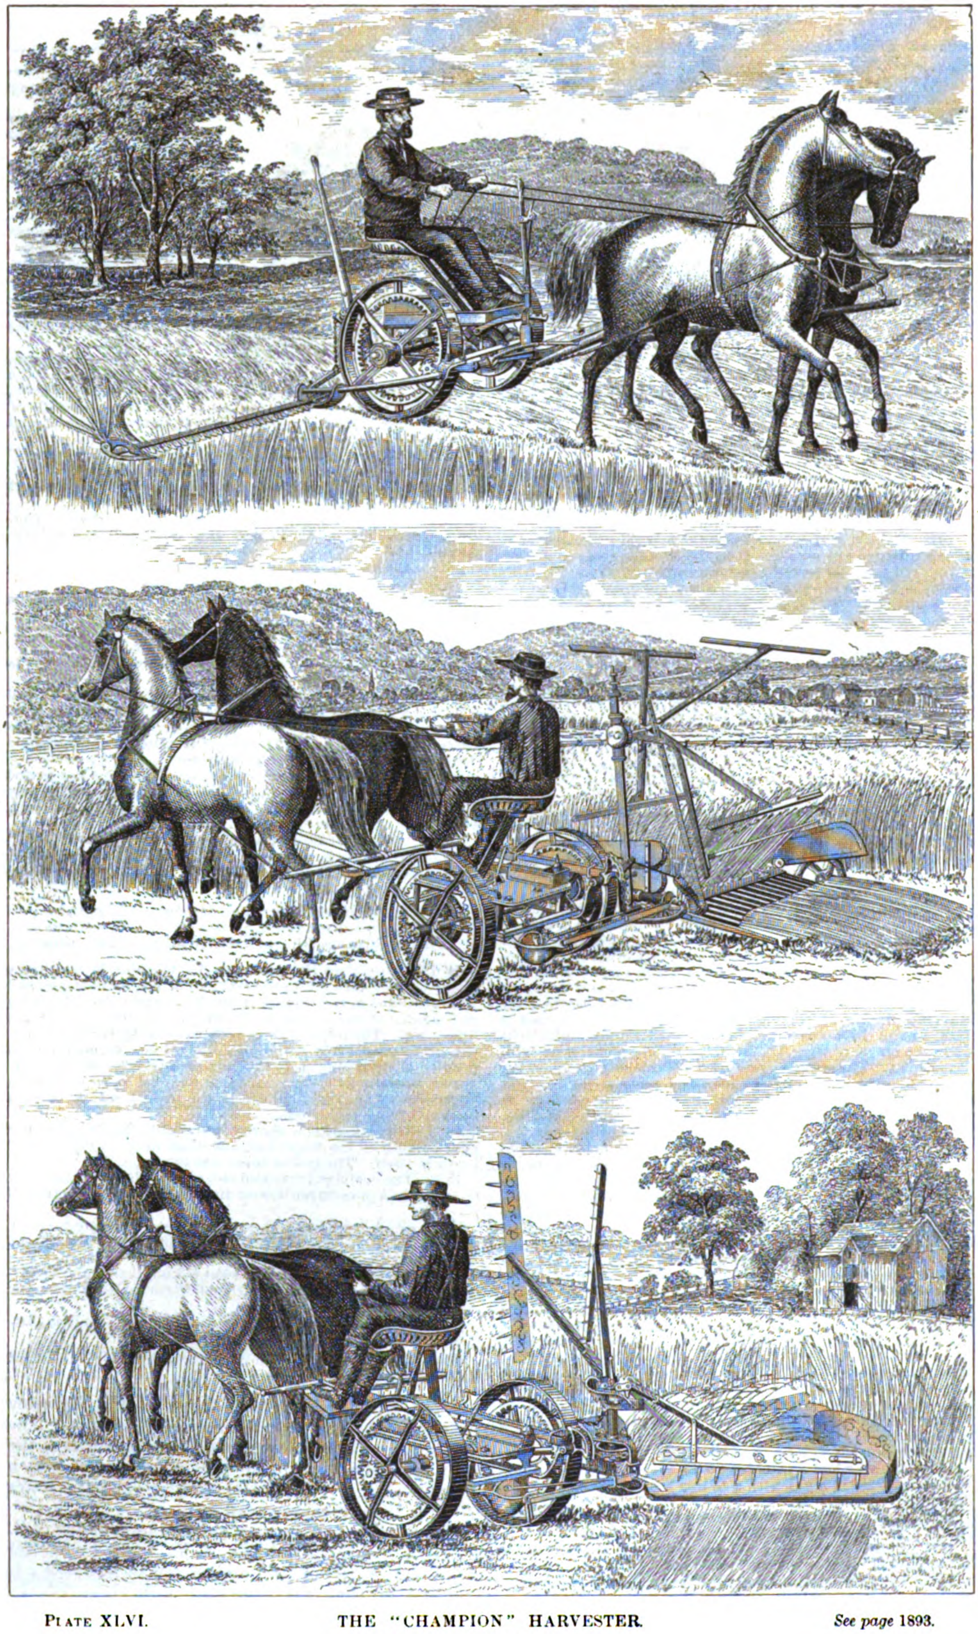


PLATE XLVI. THE "CHAMPION" HARVESTER. See page 1893.

As a Mower: a Dropper: a Self-Raker.

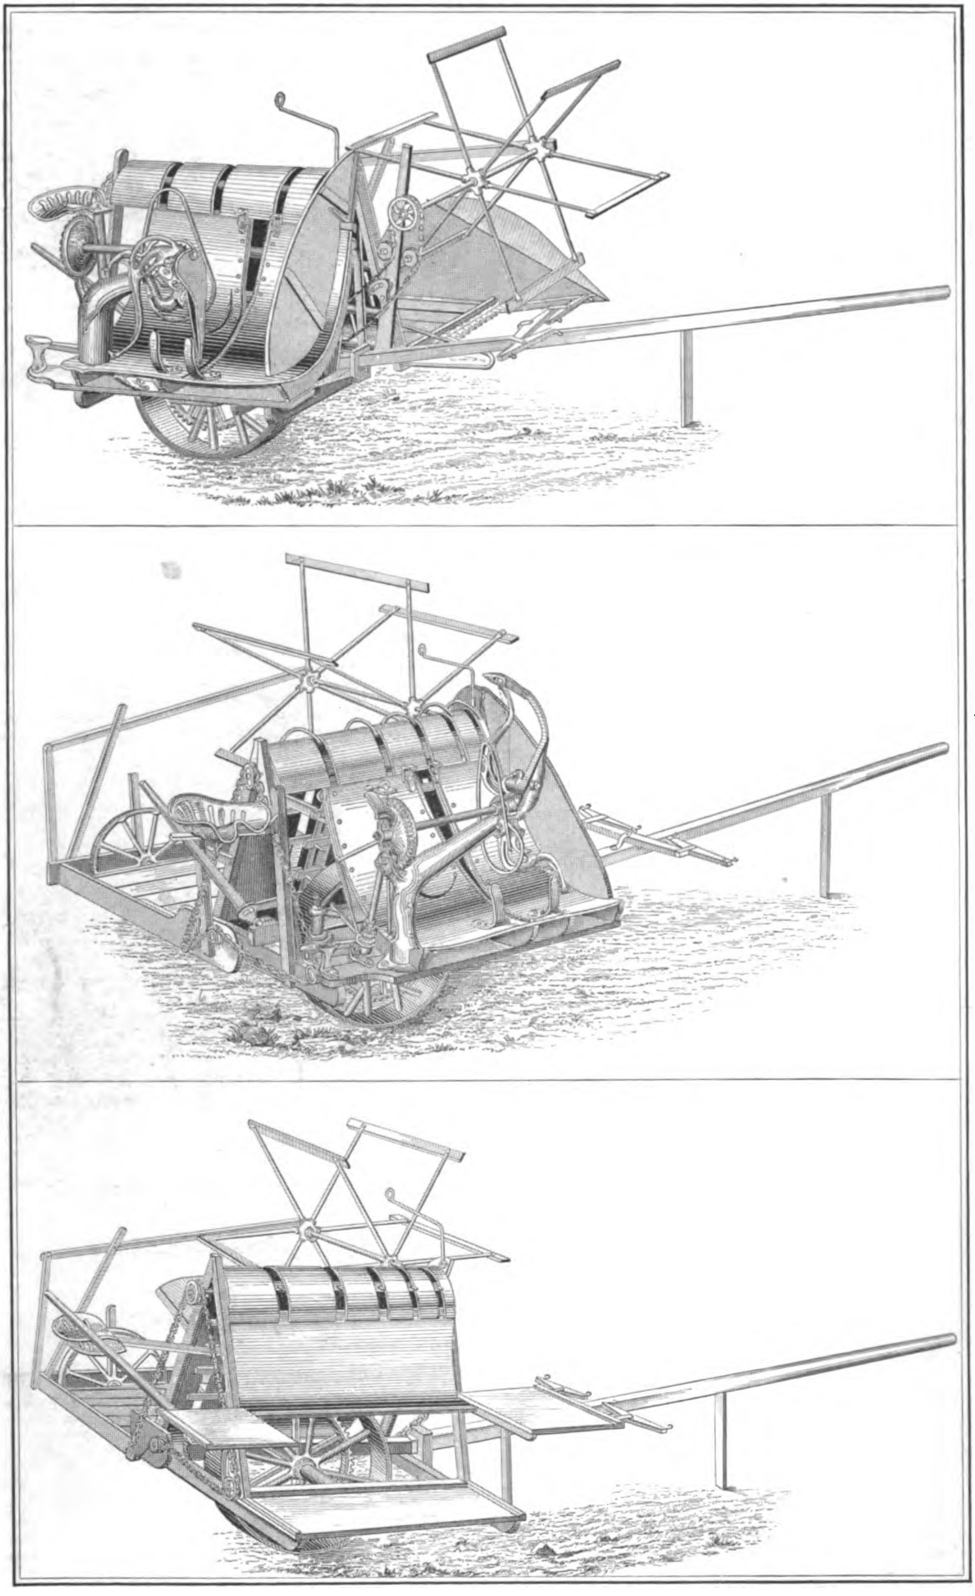

PLATE LI. SYLVANUS D. LOCKE'S HARVESTER AND BINDER. *See page* 1893.

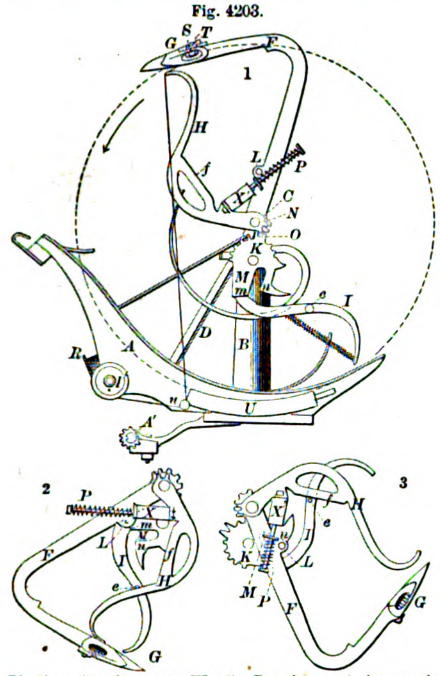
(*Machine of* 1874. WALTER A. WOOD, *Manufacturer.*)

Fig. 4203.



Binding Attachment to Wood's Reaping and Automatic Binding-Machine.

binding problem, after persistent attempts for twelve years past. Some of the machines were sent into the harvest-fields the past summer (1874), and a thousand will probably go out next season.

The grain, as it is cut, falls upon a continuously moving, side-delivery, elevating carrier, and is delivered into the cradle or receptacle *A* of the binder, the operative mechanism of which comprises a right arm *F*, which carries the head *G* with the end of the binding wire and the twisting device, and a compressing arm *H*, both rotating upon a common axis above the cradle, and a vibrating left arm *I*, moving upon an axis parallel with the axis of the arm *F*.

The arm *I* is vibrated by the rotation of the arm *F*; in one direction by segment-gear teeth, and in the other direction by a cam and pin.

The motive power is derived from the driving-wheel of the reaper, and is transmitted to the binding arms through a series of shafts with connecting gear-wheels, supported by a crane-post *B*; a treadle-clutch serves to gear or ungear the binding mechanism at will. The binding-wire is supplied from a reel *R* mounted beneath the cradle *A*, and its feed is controlled by a spring take-up and tension *I'*.

The end of the binding-wire is held by a nipper at *T*, and from thence passes down through a slit in head *G*, between the leaves of a pinion *S* contained in said head, and thence over the extremity of arm *H* down to the guide-pulley *u* and to the reel.

The rotation of arm *F*, from the position shown in Fig. 1, is accompanied by a movement of the arm *I* in an opposite direction, to bundle, compress, and hold the straw between the arms *H* and *I* (as shown at 2), while the head *G* is conveying the binding-wire completely around it and fastening the ends. The arm *I* then relaxes its pressure, and the bound sheaf is discharged (3). The running and standing parts of the wire are brought together beneath the sheaf by the passage of the head G close to the guide-pulley *u*, whereby the standing part is led into the mouth of the head *G* and between the leaves of the pulley *S* on the side opposite to the end of the wire; at the next moment the head *G* strikes into the rack-box *U*, and the gripper at *T* is caused to open and release the end of the wire, and immediately close again, severing the standing wire outside of the pinion *S* and gripping the new end. The pinion *S* is immediately thereafter caused to revolve by engaging with the rack *U*, to twist together the ends of the wire and complete the band.

In addition to the above general movements may be mentioned the following: When the arm *F* has nearly reached the position shown in Fig. 1, the long teeth *O* engage with the corresponding teeth *N* and advance the arm *H* more rapidly than the arm *F*. This pushes the wire forward, and ensures its engagement with the pinion *S*. When the arm *H* recovers its position by the action of the spring *P*, the wire is retained in engagement with the pinion *S* by a ledge or stop on the under side of the head *G*. The spring *X'* permits the arm *H* to compress the sheaf with an elastic pressure The arms *H* and *I* continue to approach each other until their segment-gears disengage, when the movement of the arm *I* becomes coincident with the movement of arm *F* (2). This is ensured by the engagement of the pin *L* with the shoulder *m* and slot *M*. When the pin *L* reaches the bottom of the slot and impinges against its front side *n*, the arm *I* is advanced faster than the arm *F*, and the sheaf is thereby released (3). The final discharge is facilitated by the engagement of the pin *e* with the cam-surface *f*, whereby the compressor *H* is caused to advance faster than the arm *F* and discharge the sheaf from the machine.

This apparatus is constructed so as to be easily removed from the reaper, either to facilitate transportation, or to permit its place to be occupied by a platform and stand for hand-binders. It is also constructed so that the removal of the arm *I* and some slight changes in other parts of the apparatus enable it to discharge the grain in unbound gavels as a dropper

Plate LI shows the machine as a binder in two positions, and also as a hand-binder. In the latter case the two men stand upon the platform and alternately take the gavels from the cradle in which the grain accumulates as it falls down the incline. Each turns to his own binding-table, fastens his band, tips the sheaf off into the stubble, and then turns to gather another gavel.

Among the successful binders must also be noticed that of James F. Gordon, of Rochester, New York. See his patents of August 27, 1872; June 16, 1874; June 30, 1874. Speaking in general terms, his machine has an elevated side delivery, by means of a traveling apron, the grain slides down an incline till arrested by a revolving gaveler, and lies in the bight of the binding-wire. The end of the binding-arm is thrown forward into the twister, carrying the wire around the gavel: the binder-frame then reciprocates, the band is twisted, followed by the cutting of the wire, unclosing of the binder-arm, and dropping of the sheaf.

Barta's self-binder (1871) has also worked successfully in the field. It uses cord, makes a square knot, and binds a gavel of any size, even no larger than the arm.

The following automatic binders may also be consulted: —

See page 1893.

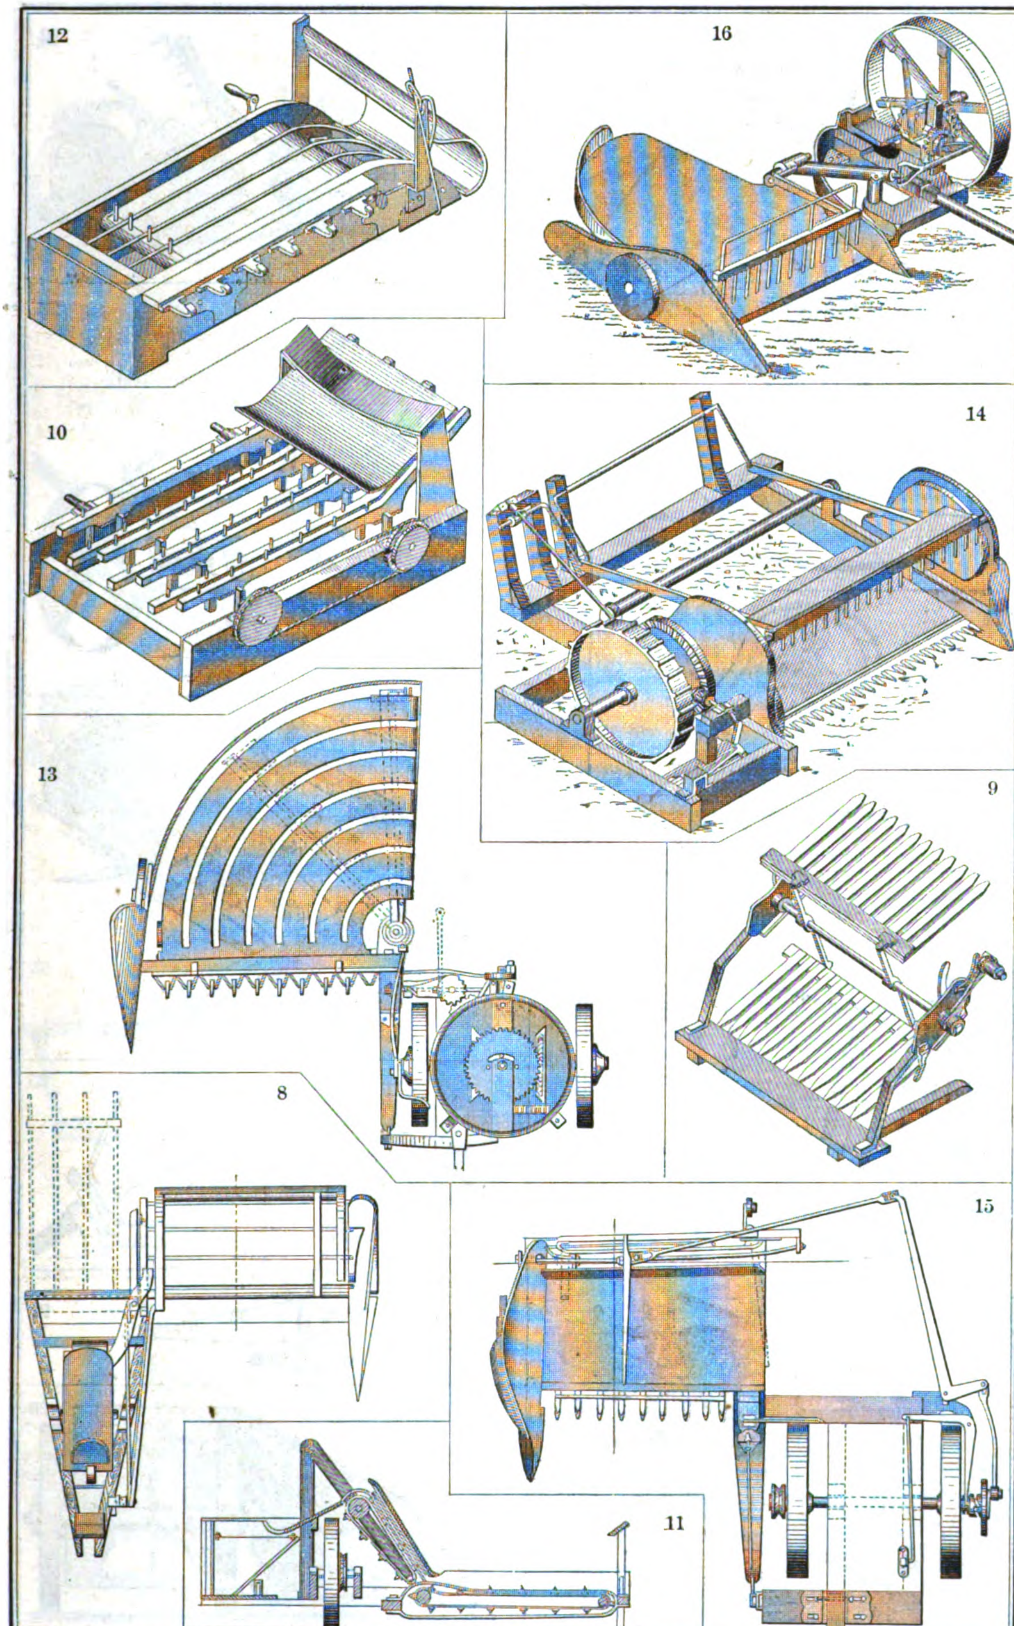

PLATE XLVIII. **REAPING MACHINES.** *(Principles of Action.)* *See page 1893.*

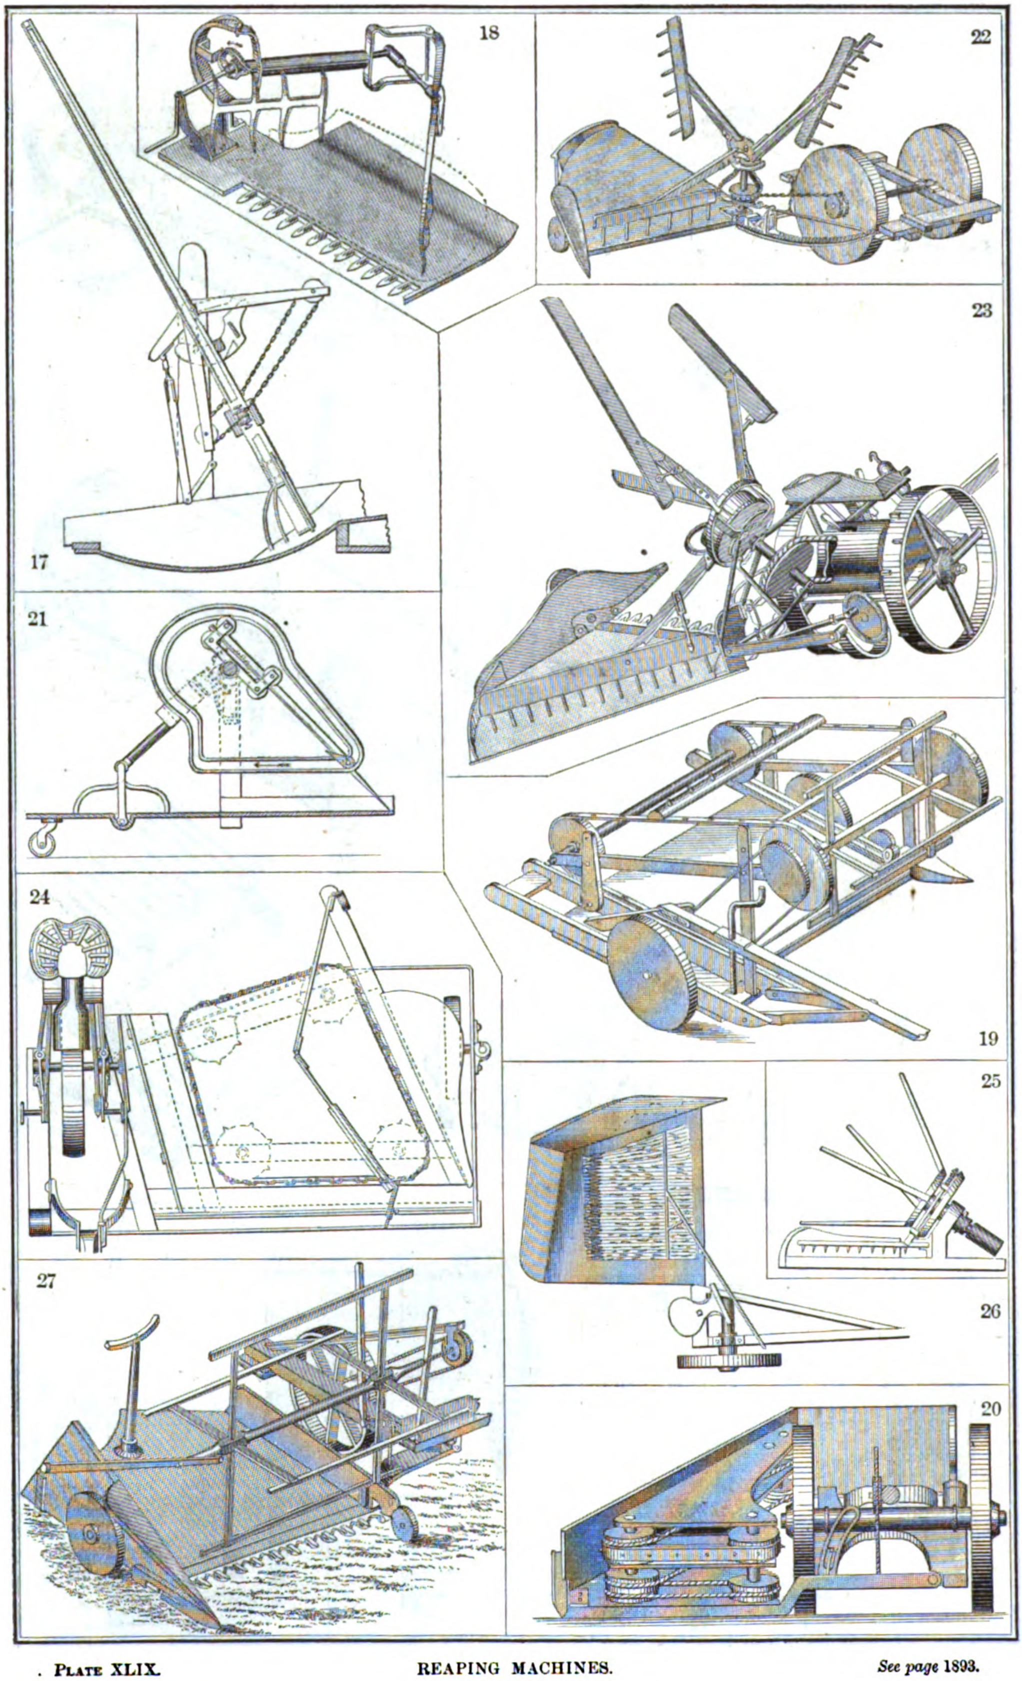

. PLATE XLIX. REAPING MACHINES. See page 1893.

(*Principles of Action.*)

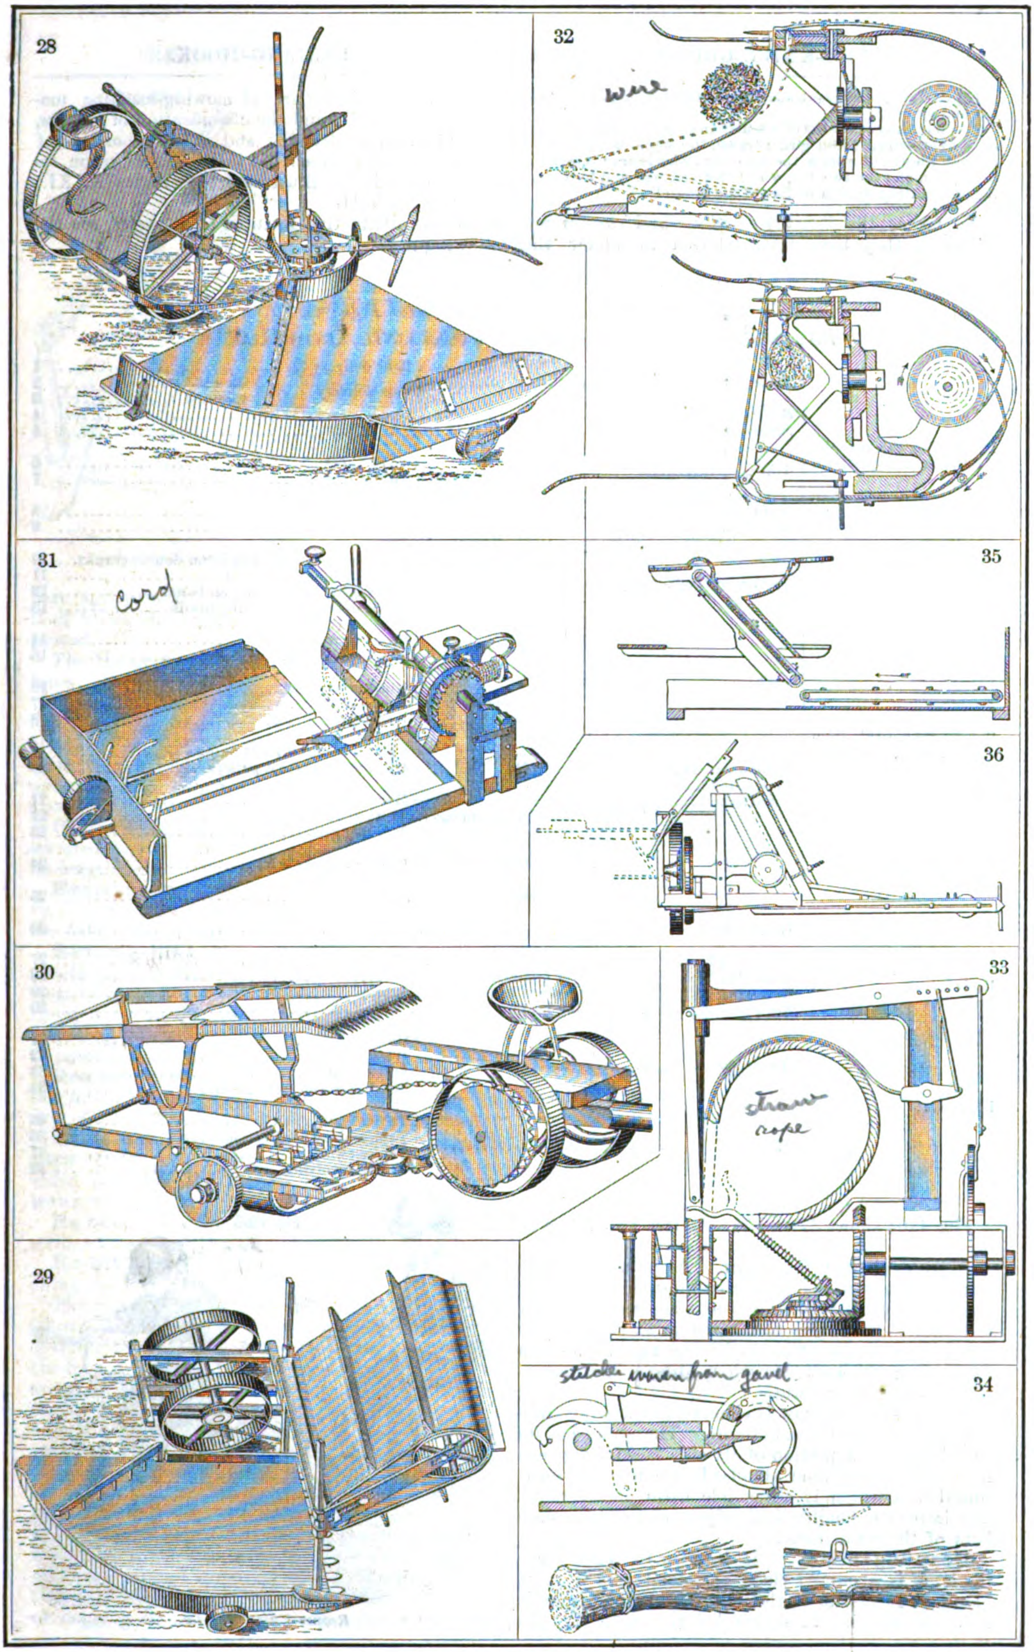

PLATE L. **REAPING MACHINES.** *(Principles of Action.)* *See page 1893.*

Fig. 3247, page 1488, is an adaptation of a steam-engine to reaping and mowing.

The implement consists of a boiler and steam-engine, erected on a light wrought-iron girder-frame, the whole being carried on four wheels, of which the two hind wheels are utilized for propulsion and the two fore wheels for steerage and for carrying the cutting apparatus free of the ground.

So far as the *mowing-machines* and *reapers* are identical, they have been referred to under the former head. See chart of mowing-machine motions, Plate XXX., and the classification of *mowers*, page 1488. The drawing and cutting portions of the apparatus are described in the classification referred to, and are illustrated on Plates XXXI., XXXII., XXXIII.

For the distinctive features of a reaper, see the following: —

Classification of Reapers by Structural Features.

The numbers refer to corresponding numbers on Plates XLVII., XLVIII., XLIX., L.

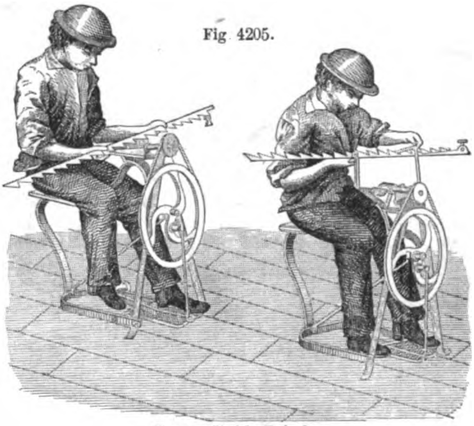
Fig. 4204 shows 37 and 38, the last two forms of binders cited in the classification.

Reap'er-knife Grind'er. A form of grindstone or emery-wheel for sharpening the knives or sickle sections of reaping and mowing machines. In the figure, one shows the machine as adapted for grinding, and the other as having two knife-rests for holding the knife-bar when filing. The emery-wheel is driven by treadle.

Fig. 4205.

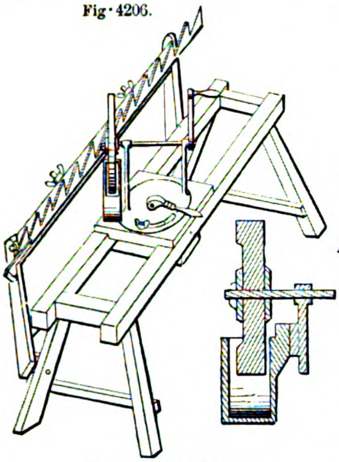


Reaper-Knife Grinder.

In Fig. 4206, the saw is clamped to the adjustable bar at the top of the side frame. The stone has its periphery and a portion of its side faced for grinding. The grindstone standards are upon a horizontal disk which is adjustable upon the carriage. The latter has longitudinal adjustment on the slide bars of the main frame.

Reap'ing-hook. (*Husbandry.*) The reaping-hook is a curved blade of steel set in a short handle. It has no teeth, and this distinguishes it from the sickle. It superseded the sickle in the

Fig. 4206.



Reaper-Knife Sharpener.

Fig. 4207.

Reaping-Hooks.

best agricultural counties of England before the reaping-machine appeared.

The Hainault scythe is a reaping-hook. See SCYTHE.

It is called the *scythe-hook* in Scotland, and is there credited to the Irish. The Dutch hook is broad, thin, more nearly circular, but does not *reach* into the grain so far. Ichabod!

Hutton's reaping-hook (English) is serrated from the point through half its length only.

Reap′ing-ma-chine′. (*Husbandry.*) A machine for cutting grain in the field. See REAPER.

Rear′ing-bit. (*Menage.*) A bit having a curved mouth-piece, which forms the flattened side of a ring, to each side of which are attached driving-rein rings, while on the lower side is another ring of the same size, into which the martingale-strap is buckled, to prevent the horse lifting his head when rearing.

Rea′son-piece. (*Building.*) A timber which lies under the beams on the brick or timber in the side of a house. A *wall-plate. Raising-piece.*

Reau′mur Ther-mom′e-ter. One in which the space between the freezing and boiling points is divided into 80°, the former being 0°. See THERMOMETER.

Re′bec. (*Music.*) A Moorish violin with three strings tuned in fifths, and played with a bow.

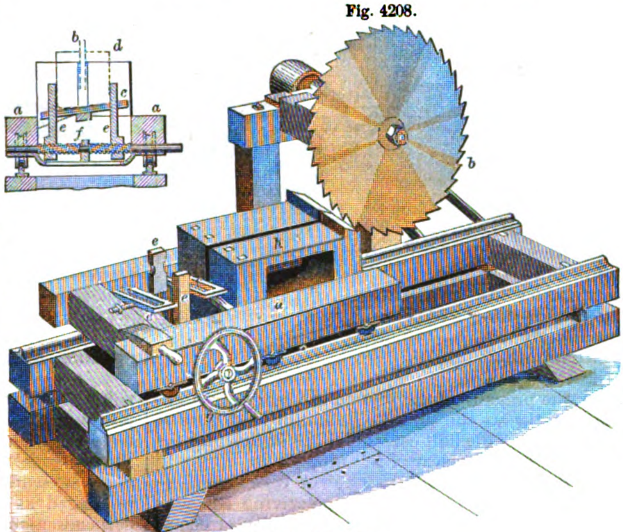
Re-bit′ing. (*Engraving.*) A process for deepening the lines on engraved plates.

The plate is cleaned perfectly and the surface polished. A *ground* is then carefully made by a *dabber*, covering the face only of the plate and not clogging the lines. The parts which do not require *rebiting* are *stopped out*. A wall of wax is then laid around the engraving, the acid solution is poured on, and is allowed to remain till the required depth of lines is attained. As each portion acquires the required depth it is *stopped out*, and the *biting-in* resumed on the remaining exposed parts. See GROUND; ETCHING; BITING-IN; LINE-ENGRAVING, etc.

Re-bolt′ing-ma-chine′. A species of sawing-machine for rebolting large blocks of timber without quite separating the smaller bolts from each other, so that they will hold together, admitting of handling or dogging in the shingling or other machine in which they are to be finally cut up. By this means the machine may be supplied with timber to its full working capacity, while, at the same time, cutting the shingles or other pieces as narrow as desired.

In the perspective view (Fig. 4208) *a* is the carriage which moves under the saw *b*. The depth of the carriage under the blade is such that the latter does not reach the bottom, so that the bolt, secured in the saw-carriage and shown by dotted lines, will not be cut entirely through at *d* in the section. *c* is a tilting rest for the bolt, upon which the sap side of the latter, generally bevel to the other sides, is placed, and held so that the saw kerf will pass down to such a depth as to leave sufficient wood to hold the portions together. *e*, core-clamps which work upon right and left hand screws *f*, and are operated by the crank *g*. These serve to hold the bolts securely while being cut. A portion of the carriage *h* is elevated, in order to accommodate pieces which are to be divided entirely, as in ordinary sawing-machines.

Fig. 4208.

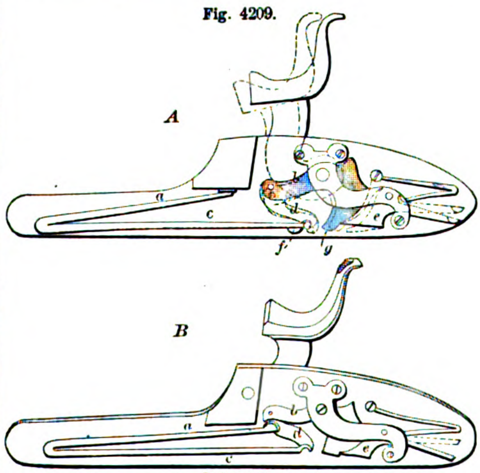


Rebolting-Machine.

The track of the carriage is made in two portions, one above the other, so that the upper part can be vertically adjusted as may be required, for saws of different sizes, or as the blade wears away.

Re-bound′er. (*Fire-arms.*) A device in a gun-lock for throwing the hammer back from the nipple after striking and exploding the cap.

Fig. 4209.

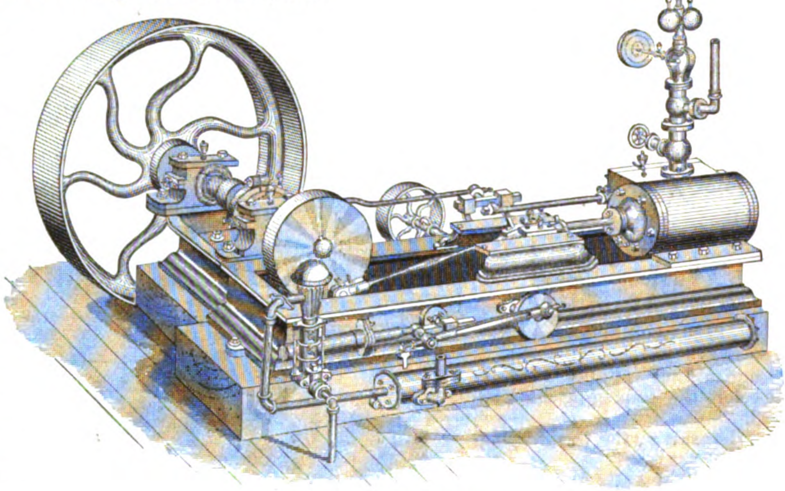


Rebounders.

This is usually effected, as at *B*, Fig. 4209, by lengthening the shorter branch *a* of the main-spring so that the arm *b* of the tumbler shall strike it just previous to the impact of the hammer on the cap, caused by the action of the long branch *c* of the main-spring transmitted through the swivel *d*; the effort made by the branch *c* in restoring itself, after the momentary compression, throws back the tumbler sufficiently far to permit the sear *e* to enter the half-cock notch.

In Dane's patent (*A*), used in the Parker gun (see SHOT-GUN), the long branch of the main-spring is arrested by a stop *f* at about the position of half-cock, the tumbler being carried forward by its momentum until it strikes the cap, when the pressure of the sear on the cam-shaped extension *g* throws the tumbler back until the nose of the sear enters the half-cock notch, or sufficiently far to lift the hammer clear of the nipple.

Fig. 4211.



Reciprocating-Engine.

Re-ceiv'er. 1. (*Chemistry.*) A vessel connected with the neck of a retort for receiving the products evolved therefrom during distillation or chemical reaction. See ALEMBIC; CONDENSER; STILL.

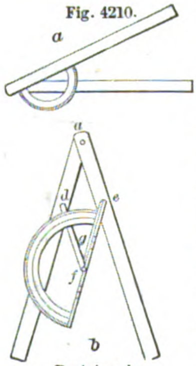
In the laboratory it is frequently made of glass, and is of globular form, but may be of any convenient shape; the material must, however, be such as will not be acted on by the substances to be decomposed or produced during the operation.

2. (*Pneumatics.*) *a.* The bell-glass on the table of an air-pump.

b. The vessel which is adapted to collect the gas from the PNEUMATIC TROUGH (which see); or to contain gas for blow-pipes, exhibitions of stereopticons, oxyhydrogen light, or microscopes.

Re-ceiv'ing-mag'net. (*Telegraphy.*) An electro-magnet through which the current from the line wire passes and is intensified, in order to actuate the sounding or recording mechanism.

Fig. 4210.



Recipiangles.

Re-cip'i-an'gle. An instrument (*a*) with two legs and a graduated arc, used by military engineers for measuring and laying off angles of fortifications. The legs are attached at one end by a double-headed screw, which forms the axis. The center of the protractor is applied at the reëntering angle of the instrument, and its graduated margin shows the angle of divergence of the legs.

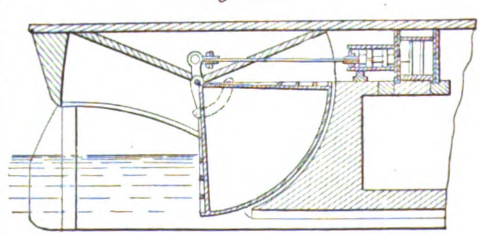
Another form (*b*) of the *recipiangle*, called the *parallelogrammatic*, has two links connecting the legs and meeting at the center *f*. The length between the points *a d* and *a e* is exactly equal to the distances *d f* and *e f*, so that when the legs are brought into line, the point *f* coincides with the point *a*. The center of the protractor is exactly over the point *f*, which also bisects the angle of the instrument at all adjustments. The marginal graduation of the protractor permits the angle subtended thereby to be read. The protractor is hinged at *g*, so that it may be lifted and stand perpendicular to the plane of the instrument. The instrument is adapted for taking salient or reëntering angles.

Re-cip'ro-cat'ing-en'gine. (*Steam-engine.*) The common form of engine, in which the piston and piston-rod move back and forth in a straight line, absolutely as in the cut, or relatively to the cylinder, as in oscillating-cylinder engines.

The term is used in contradistinction to ROTARY-PISTON ENGINE (which see), and is a very general one, including as it does by far the greater number of steam-engines, either devised or in use.

Re-cip'ro-cat'ing-pro-pel'ler. One having a paddle which has a limited stroke and returns in the same path. The propeller is reciprocated by a horizontal engine. It is enveloped at the sides and before, so that the water does not impinge against its forward side. The propeller is made sufficiently buoyant to raise it to position for making the effective stroke.

Fig. 4212.

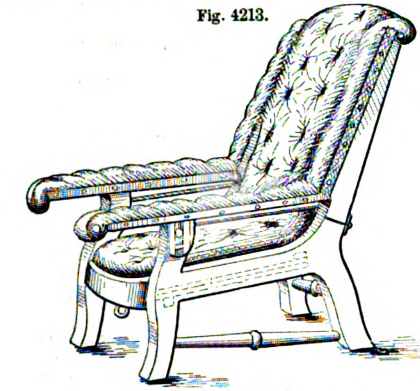


Reciprocating-Propeller.

Re-clin'ing-chair. One whose back admits of

being tilted, allowing the occupant to assume an inclined or recumbent posture. In the figure, the back is hinged near the seat, and a given inclination is maintained by the engagement of notches beneath

Fig. 4213.



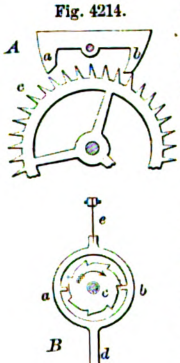
Reclining-Chair.

the arms, with spring teeth on the front posts. A slide in front forms a foot-rest. Spring cords erect the back. See FOLDING-CHAIR; INVALID-CHAIR; CAR-SEAT.

Re-coil'-es-cape'ment. A recoil-escapement is one in which, after the pallets leave the teeth at each oscillation of the pendulum, the extremities of the teeth slide along the surfaces of the pallets, and thereby give an impulse to the pendulum or balance.

The *vertical* escapement of a watch is a *recoil*, and the word is used as distinguished from a *dead-beat.* In the former there is a recoil of the train, and in the latter the impinging surfaces of the pallets are cut to a curve concentric with the axis of vibration, and during the time one of the teeth is against the pallet the scape-wheel remains perfectly at rest. See ESCAPEMENT; DEAD-BEAT.

Fig. 4214.



Recoil Clock-Escapements.

The anchor-escapement *A* was invented by Clement, of London, about 1680. The anchor is caused to vibrate on its axis by the oscillations of the pendulum. The teeth of the scape-wheel *c* impinge alternately against the outer surface of pallet *b* and the inner surface of pallet *a*. As these surfaces are not concentric with the axis of oscillation, a *recoil* of the train ensues, for the reason just stated, that as the pallets leave the teeth, the extremities of the latter slide along the acting surfaces of the pallets, and through them transmit a sufficient impulse to the pendulum to overcome the loss by friction and the resistance of the atmosphere. See also Fig. 193, page 97.

Another clock-escapement *B* has a pallet-ring surrounding the scape-wheel *c*, the pallets *a b* projecting from its internal periphery and catching alternately, as the pendulum rod *d* oscillates, upon teeth on opposite sides of the scape-wheel.

The pallet-ring is suspended by a piece of watch-spring *e* from a stud.

Re-cord'er. 1. (*Music.*) A musical instrument like a flageolet.

"Flutes and soft recorders."
MILTON.

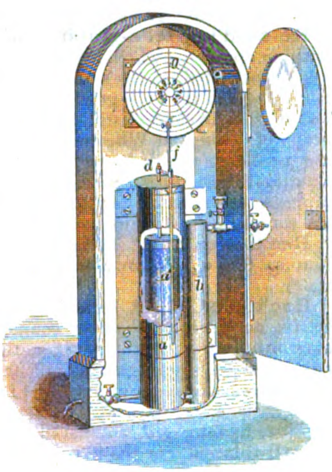
"To Drumbleby's, and there did talk a great deal about pipes; and did buy a recorder." — PEPYS'S *Diary*, 1668.

It was used in teaching birds to pipe.

2. A registering apparatus. See REGISTER.

Re-cord'ing-gage. Generally speaking, any gage provided with means for leaving a visible record of its indications.

Fig 4215.

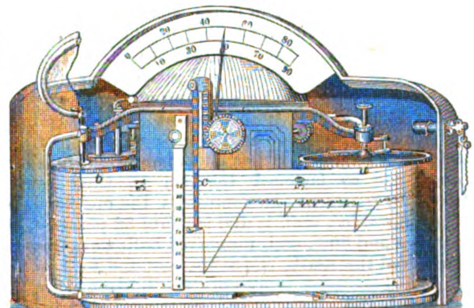


Recording-Gage for Gas.

That shown (Fig. 4215) is particularly designed for measuring gas pressures. The two cylinders *a b* connected by a short pipe *c* are partially filled with water. *a* contains a float *a'* having an upwardly projecting rod *d* passing through a hole in its cover and connected with a guide-rod which carries a pencil-holder at the end of a flexible spring *f*, by which the pencil is caused to press against a disk of cardboard *g*, ruled with radial divisions for the hours and circular divisions for inches of pressure, and rotated by clock-work. Gas being admitted to the upper part of the cylinder *b* depresses the water therein, and causes a difference of level in the two cylinders which varies as the gaseous pressure fluctuates, its amount being registered by the line traced by the pencil on the cardboard, which is renewed at intervals of twelve hours. See also SPEED-RECORDER.

Edson's recording-gage (Fig. 4216) has several air and steam tight connected drums made of thin elastic metal; these, on being expanded by the influx of steam, raise a rod attached to the upper drum, which operates a segment-rack connected by gearing with a horizontal rack and a pawl, causing a partial slight rotation of the drum *a*, which consequently draws forward the paper previously wound upon the roll *b*, on to itself. The expansion or contraction of the connected drums also raises or depresses the arm

Fig. 4216.



Edson's Recording Steam-Gage.

c, carrying a pencil or tracer at its lower extremity, making vertical or diagonal lines on the paper, which is ruled with horizontal lines indicating pounds, as the steam-pressure varies. The rolls may also be rotated by connection with the engine, affording a more continuous record. A graduated arc and pointer are attached, to more conveniently show the pressure at the moment; and a hammer and bell or other device may also be connected to sound an alarm when the pressure exceeds a given amount. See STEAM-GAGE.

Re-cord'ing-tel'e-graph. A telegraph provided with an apparatus which makes a record of the message transmitted, as the symbol telegraphs of Morse and Bain, and the type-printing telegraphs of House and Hughes, in contradistinction to the indicator-telegraph of Cooke and Wheatstone, which has a pointing needle or needles, and the audible one of Sir Charles Bright, which sounds upon bells, and the Morse as at present generally used, which is read by the sounds. See List under TELEGRAPH.

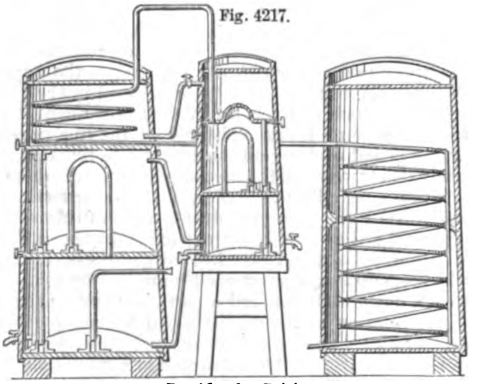
Rec'ti-fi-ca'tion. Redistillation or resublimation to free a substance from impurities or from water.

Rec'ti-fi'er. 1. A second still for redistilling spirits, or a second chamber connected to the main or primary still. In the rectifier, the *low wines* are redistilled to concentrate them; or *high wines* are farther concentrated and purified to form alcohol.

In some cases, flavoring matters, such as oil of juniper, to form gin, are placed with the *low wines* for redistillation: or the flavor is added in the form of vapor.

In Fig. 4217, the tub has three chambers and means for heating the *singlings* before charging the lower chambers, so as not to check the continuous

Fig. 4217.



Rectifier for Spirits.

process of evaporation incident to the use of a single-chambered vessel. The upper chamber receives the low wines, and they are heated by the steam in the middle chamber. The chambers are charged successively from the upper one, and provision is made for avoiding collapse and for carrying off vapor.

2. (*Nautical.*) An instrument for determining the variation of the compass on board ship. It consists of two circles, either laid upon or let into each other, and so fastened together in their centers that they represent two compasses, the one fixed, the other movable; each is divided into 32 points of the compass and 360°, and, numbered both ways from the north and the south, end at the east and west in 90°. The fixed compass represents the horizon, in which the north and all the other points are liable to variation. — ADMIRAL SMYTH.

Re-dan'. (*Fortification.*) A work having two faces forming a salient angle in the direction from which an attack may be expected; it is open at the gorge.

Fig 4218.

Redans.

A *double redan* (*b*), or *bonnet deprêtre*, has a reëntering angle for mutual defense.

The *redan* is the simplest field-work, and is used for defending the avenues of approach to a village, bridge, or defile.

In front of another field-work, it is called a *flèche*.

When *flanks* are added to the *faces*, the work becomes a *detached bastion* or *lunette*.

Red Brass. An alloy containing 8 parts copper and 3 zinc.

Red Brick-dust. (*Foundry.*) Used as *parting-sand* (which see).

Re-doubt'. (*Fortification.*) *a.* A detached field-work inclosed by a parapet, the salient points of which are but imperfectly or not at all protected by a flank fire. It may be square, star-shaped, or irregular in plan, according to the requirements of its site and surroundings.

b. An interior work within the main line of ramparts, as the *redoubt* of the *ravelin*, *redoubt* in the *places-of-arms*. See RAVELIN.

These are designed as places of assemblage in offensive exterior operations, or for retreat in case of a repulse.

Red-short I'ron. Iron which is difficult to weld and is brittle when heated is said to be *red-short* or *hot-short*. This defect is due to the presence of sulphur.

Red-staff. (*Milling.*) A straight-edge employed to detect irregularities in the face of a mill-stone. The edge is reddened with ocher, and colors prominent irregularities on the face of the stone.

Red-stuff. A trade term for the oxides of iron used in grinding and polishing, such as *crocus* and *rouge*.

Red Tom'bac. An alloy containing 11 parts copper and 1 zinc.

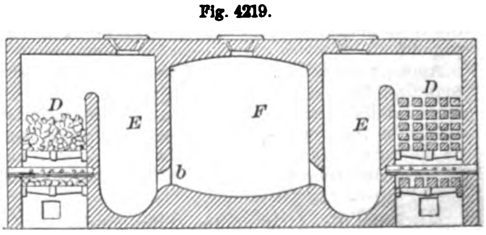
Re-duc'ing-fur'nace. (*Metallurgy.*) A furnace in which ores are deprived of their oxygen and reduced to the metallic state by the action of intensely heated vapors containing carbon, sometimes assisted by other reagents.

It is generally of the reverberatory kind, and is used in the reduction of litharge, the treatment of copper ore in several stages, and for obtaining the precious metals. See BLAST-FURNACE; REVERBERATORY-FURNACE; SMELTING-FURNACE; and others cited in the lists under METALLURGY and FURNACE.

Siemen's furnace has two parallel sides sloping downward, so as to form a kind of trough between them. The ore is charged at both sides on the top of the furnace, and slides down the inclined planes of the two sloping sides. At the bottom of the furnace the gases from the producer and the necessary supply of air are admitted, and produce an intense flame, the products of combustion rising upward through the masses of ore, which are acted upon in a similar manner to that in the blast furnace.

Maunton's furnace (Fig. 4219) has regenerators *D D* and

Fig. 4219.

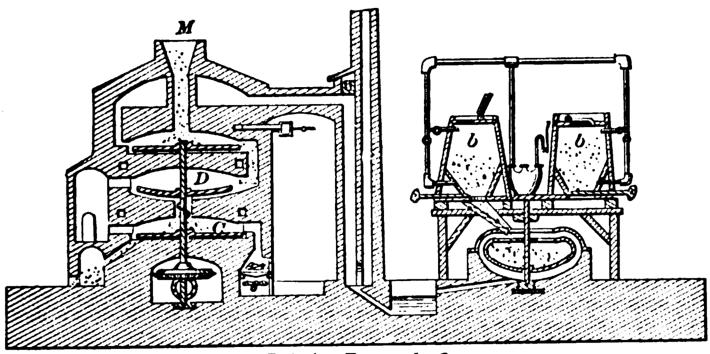


Reducing-Furnace for Ores.

fuel-chambers *E E* on each side of the reducing-chamber *F*, which is charged with finely comminuted ore. The hot-air blast is caused to pass into the reducing-chamber *F* alternately from the regenerators *D D* through openings *b* at its base.

In Ott's furnace for reducing the precious metals (Fig. 4220), the ore, having previously been separated from a portion of its impurities, may be mixed with two to four per cent of sodium, potassium, calcium, magnesium, iron, copper, or with their hypochlorites. The ore, dry or with water, is introduced through the funnel *M*. In the upper oven the ore is heated. In the second oven *D*, where sulphur is eliminated, the steam and hot air are injected, and most of the sulphur is carried off. In the lower oven *C* it is farther heated and treated with hydro-carbonaceous vapors from the furnace to decompose the sulphates. The volatile metals passing off from this chamber are condensed

Fig. 4220.



Ott's Reducing-Furnace for Ores.

in the shower-bath of the diving-flue. Hyponitrous-acid gas or oxygen may be introduced into the furnace. If the ore be auriferous it is placed in the tanks *b b*, dampened with steam, and saturated with chlorine gas, after which it is treated in the centrifugal machine. If the ore be argentiferous it is brought from the furnace immediately to the centrifugal machine and treated with hot water returned several times over and over the same ore, and the liquid resulting from that treatment is pumped up from the lower tank to the upper tank, and from thence falls in a fine shower down the diving-flue, where the sulphureted hydrogen produced in the furnace precipitates the silver in form of sulphite. This is repeated several times. The sulphite is melted with iron, producing sulphuret of iron and silver.

Re-duc′tion-com′pass-es. *Proportional* dividers or *whole-and-half* dividers.

Reed. 1. (*Weaving.*) Called also the *sley* or *slay*. An appurtenance of the loom, consisting of two parallel bars set a few inches apart and furnished with a number of parallel slips of metal or reed, called *dents*, between which the warp-threads are passed. The lengths of reeds are estimated in quarters of a yard, as $\frac{3}{4}$, $\frac{4}{4}$, $\frac{5}{4}$, $\frac{6}{4}$, etc., and, if necessary, by a smaller fractional denominator, as $\frac{7}{8}$, $\frac{9}{8}$, or $\frac{13}{16}$, $\frac{15}{16}$, etc.

In Scotland they are estimated thus: —

20 splits .... 1 porter.
5 porters .... 1 hundred.

In other parts of Britain the estimate is by the number of *splits* or *dents* in 24½ inches, or in 1 inch.

The reed is set in a swinging frame, called the *lathe*, *lay*, or *batten*. In the hand-lathe, the bottom of the batten is furnished with a shelf, called the *shuttle-race*, along which the shuttle is driven.

The office of the reed is to beat the *weft* up to the *web*, and the force of the blow determines the compactness of the fabric. Two threads of yarn pass between each of the *reed-splits* or *dents*.

The number of *dents* in a reed of a given length determines the fineness of the cloth.

One form of linen-prover has 4 perforations to adapt it to the varying modes of estimating. The number of threads visible in this perforation ascertains the number of threads in the standard measure of the *reed*.

The first is ¼ of an inch in diameter, and is intended to ascertain the number of threads per inch.

The second is for the Holland reed, being $^1/_{200}$ part of 40 inches.

The third is $^1/_{700}$ part of 37 inches, and is adapted to the Scotch reed, so called by Ure, as being the regulation reed of that country.

The fourth is $^1/_{200}$ of 84 inches, and is adapted for the French cambrics.

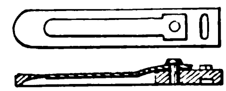
Two warp-threads count for 1 split.

2. (*Music.*) *a*. Formerly, an instrument made from a reed with holes to be stopped by the fingers.

b. A vibrating musical tongue of wood or metal (formerly made from a *reed*).

It is used in wind-instruments of two classes.

Fig. 4221.



Melodeon-Reed.

1. The *oboe*, *clarinet*, *bassoon*.

2. The *accordeon*, *concertina*, *melodeon*, *harmonium*, *parlor-organ*, and that variety of pipe in the large organ known as the *reed-pipe*, in contradistinction to the *flute* or *mouth pipe*. See ORGAN-PIPE.

Some reeds batter against the seat and some are *free*.

3. (*Mining.*) The tube conveying the train to the charge in the blast-hole. Also called the *spire*.

4. (*Ornamentation.*) *a*. Semi-cylindrical ridges, closely arranged in parallel order and designed for ornament.

b. A succession of beads on an object.

Reed′ing. This term is applied (technically) to the *nurling* on the edge of coins. It was originally placed upon coin to prevent it being filed away or clipped. It is done at the same time that the impression is given to the obverse and reverse faces of the coin, the collar which holds the blank being *fluted* or *indented* on its inner periphery for that purpose. The pressure on the dies expands the metal into the indentations of the collar, giving the *reeded* or *crenated* form to the edge.

It is sometimes called *milling*, but that term is also applied to the swaging pressure by which the edge is expanded and a flange raised, which protects the faces of the coin and enables them to be built into a pile.

Reed-or′gan. (*Music.*) A melodeon, or parlor-organ.

An organ whose pipes are provided with *reeds*, in contradistinction to the *flute* or *mouth* organ, whose pipes have a lip to cut the wind escaping through an aperture in a diaphragm. See FLUTE-ORGAN.

The *reed-pipes* consist of a foot to carry the wind to the reed, a thin tongue of hard brass, whose extremity is fitted into a mold by a wooden plug. Its free extremity is vibrated by the force of the wind, and gives a sound of a pitch proportioned to the length, thickness, and elasticity of the tongue.

The wind from the reed traverses a long pipe, which gives character and quality to the sound. Both classes of pipes are employed in large organs.

Reed-pipe. (*Music.*) An organ-pipe in which the musical tone is produced by the vibration of a metallic tongue.

In some reed-pipes the tongue is made to batter against its seat as in the clarinet; in others the tongue plays in the opening of the reed. The *free-reed* has been used in China from time

immemorial, but was introduced into Europe by M. Grenié in 1810.

The reed or tube has a longitudinal, narrow opening in front, covered by the *tongue*, which is firmly fixed to the reed at its upper end, but plays freely at the lower end, where it is somewhat bent away from the *reed*. A *turning wire* presses against the tongue so as to regulate the length of the portion subject to vibration. The reed terminates below in a cone, into which the air is driven. The shape of the tube above the cone is varied so as to obtain the required quality of tone, while the pitch depends upon the length, thickness, and elasticity of the tongue. A given number of vibrations per second are necessary to the production of a certain note; the slower the vibrations, the graver the tone, and conversely. See PIPE.

The free-reed, instead of beating on the edges of the opening, plays back and forth in the slot.

Reed-plane. (*Joinery.*) A concave-soled plane used in making beads.

Reed-stop. (*Music.*) A set of pipes furnished with *reeds*, and associated with the *flute*-stops of an organ, to give a variety to the effects.

Reef. (*Nautical.*) *a.* The portion of a square sail between the head of a sail and any of the *reef-bands*. On the *tablings* of the *leech* of the sail are *earings* and *cringles*, to which the *reef-tackle* is secured. The reef is tied up by *reef-points*, the knot being a *reef-knot*. The *first reef* in a square sail is included between the head and the upper reef-band; the *second reef* between this and the next lower reef-band, and so on.

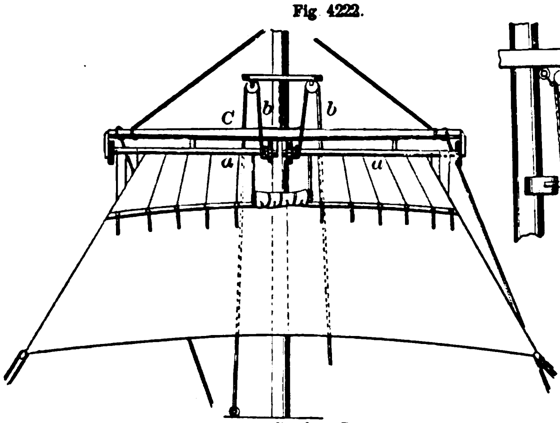
Fore-and-aft sails are reefed from the foot, the first reef being the lowest. The uppermost, called a *balance* reef, extends diagonally upward from the outer leech when *close-reefed;* that is, when all the reefs are taken in, the area of the sail exposed to the wind is reduced about one half.

The object of the reef is to diminish the surface of the sail when the wind is blowing hard.

In the ordinary process of reefing square sails, the seamen ascend the rigging and *lay out* on the yard, standing on the *horses* or foot-ropes while they gather in and secure the hauled-up portion of the sail. Many attempts have been made to avoid the necessity for this difficult and dangerous operation, which is a fruitful source of accident. The first, we believe, was by Captain Forbes, of Boston.

In Ingersoll's apparatus two rolling spars *a a* are journaled beneath and connected with the yard *C*. These are rotated by parbuckles *b b* operated from the deck; the sail is wound around

Fig. 4222.



Reefing-Gear.

them to any desired extent, and prevented from unrolling by ratchets and pawls at their ends.

b. The bowsprit of a cutter or that of a ship-of-war with a ram-bow is said to *reef* when it is run-in or shortened by sliding in-board.

c. Reefing the paddles in steamships is effected by disconnecting the float-boards from the paddle-arms, and bolting them again nearer the center of the wheel, to diminish the dip when the vessel is deep.

Reef-band. (*Nautical.*) A strong horizontal strip of canvas extending across a sail at right angles to the lengths of cloth.

In square-rigged vessels there are four of these bands to the topsails, from three to six feet apart, according to the size of the sail, and two bands to the foresail and mainsail. Fore-and-aft sails have also a band extending diagonally upward from the outer leech, for balance-reefing.

Each band is pierced with holes for the *reef-points*, by which it is tied to the yard in shortening sail.

Reef-knot. (*Nautical.*) A knot formed by passing the ends of the two parts of one rope through the loop formed by another whose two ends are similarly passed through a loop on the first; the two parts of one rope are passed above, and of the other below the loop through which they are inserted. A longitudinal pull tightens the knot, which can only be untied by pushing the loops in opposite directions.

Called also *square-knot*, *flat-hitch*.

When one end of one rope is passed above and the other below the loop it forms a *granny's-knot*.

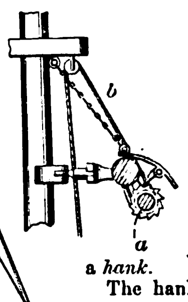
Reef-line. (*Nautical.*) A line sometimes (seldom) used in reefing. It passes spirally around the yard, and through the eyelets in the reef-band successively, so as to draw the latter up to the yard when the line is hauled upon.

Reef-pen'dant. (*Nautical.*) A tackle by which the after leech of a fore-and-aft sail is drawn down to the boom in reefing.

Reef-point. (*Nautical.*) One of the flat pieces of braided cord attached by eyelets to the *reef-band* of a sail, and serving to diminish its area.

The *reef-band* has usually two holes in each width of cloth, and the *points* taper toward each end. The small end of each is passed through an eye in the large end of the other, and being rove through the eyelets in the *reef-band*, one hangs down before and the other abaft the sail.

Reef-tack'le. (*Nautical.*) A tackle by which the *reef-cringles* on the leeches of a sail are drawn up to the yard for reefing.



Reel. A revolving device on which fiber, thread, cord, rope, fabric, etc., are wound, to form them into hanks or skeins, and for various other purposes.

1. (*Cotton-machinery.*) A machine on which cotton is wound, making hanks each having 840 yards in length of thread.

The circumference of the *reel* is 4½ feet; when it has performed 80 revolutions a *lay* is formed, measuring 120 yards, and 7 of these lays make up a *hank*.

The hank-yarn is specially designed for warps.

2. (*Silk.*) The revolving frame on which silk is wound from the cocoons, or yarn is wound off from the spindle of a hand-spinning machine, and reeled into cuts or hanks.

3. (*Rope-making.*) Spun yarns are wound on a reel preparatory to tarring or laying up into strands as the twisting of each length is completed. See ROPE.

4. (*Nautical.*) A revolving frame to hold a line or cord, as, —

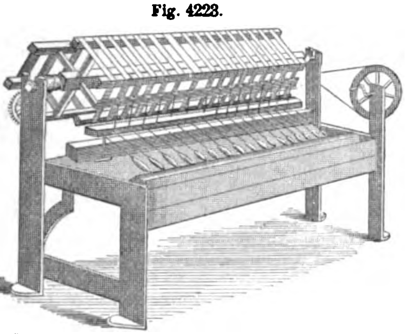
a. The *log-reel* or spool for the *log-line*. See LOG.

b. The *deep-sea* reel for the *deep-sea* lead-line of 150 or 200 fathoms. See SOUNDING.

c. The *spun-yarn* reel, etc.

5. (*Angling.*) A skeleton barrel attached to the

Fig. 4223.

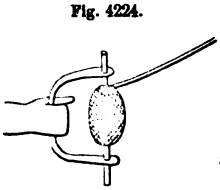


Reel for Cotton Yarns.

butt of an angler's rod, around which the inner end of the line is wound, and from which it is payed out as the fish runs off with the bait, and is gradually wound in again as his struggles become less violent, bringing him to land or to the landing-net. *A fishing-reel.*

The reel represented in the accompanying figure is from an ancient painting at Beni-Hassan, and was used for winding the cord by which the fish-spear or bident was recovered after throwing. In its construction it was merely a stirrup-shaped piece of metal, and a turning pin on which the cord was wound.

Fig. 4224.



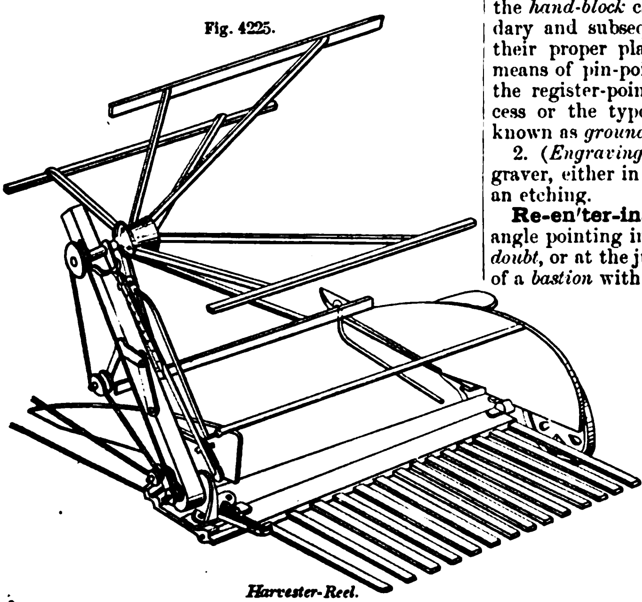
Egyptian Cord-Reel.

6. (*Telegraphy.*) A barrel on which the strip of paper for receiving the message is wound in a recording telegraph.

7. (*Oven.*) A cylinder with radial arms rotating in a heated chamber carrying pans in which loaves of bread are placed for baking in the *reel-oven.* See OVEN.

8. (*Milling.*) The barrel or drum on which the bolting cloth is fastened.

Fig. 4225.



Harvester-Reel.

9. (*Agriculture.*) A device having radial arms carrying horizontal slats, and rotated by gear or pulley connection with the axle of a harvester, for pressing backward and holding the stalks of grain in position for being severed by the knives.

The example shows the *reel* and the *dropper.* See REAPER, Plates XLIX., L.

Reel'ing-ma-chine'. (*Cotton-manufacture.*) *a.* A machine for winding the yarn off the bobbins of the spinning or twisting frames, and forming it into hanks or skeins. Fig. 4223.

b. A machine for winding thread on to reels or spools. See SPOOLING-MACHINE; SILK-REEL.

Reel-ov'en. A baker's oven in which the bread-pans are swung on the horizontal arms of a rotating reel.

The reel has a horizontal axis, which is rotated by gearing on the outside. To each arm of the reel — the number of the arms varying with the capacity of the oven — is a pendulous shelf or bread-pan. These at one part of their revolution are presented at an opening, through which the unbaked loaves are introduced, and thence pass downward toward the arch of the furnace. As each pan comes opposite to the opening it receives its load, and by the time all are filled the first one is again at the opening, the loaves baked and ready to be removed, clearing the pan for another batch. The baking is thus a continuous operation, the time of rotation of the reel being adapted to the completion of the process. In a later invention the pans, instead of being pendulous, are placed above the reel-arms, and the latter are preserved in horizontal position by pendulous weights beneath. See OVEN (Fig. 3444, page 1583).

Reem'ing. (*Shipbuilding.*) Opening the seams between planks for the insertion of new oakum.

The tool is a *reeming-iron* struck by a *reeming-beetle.*

Reem'ing-bee'tle. (*Shipbuilding.*) The larger mallet of the calker by which he drives the *reeming-iron.*

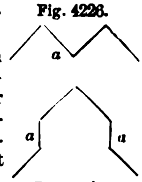
Reem'ing-i'ron. (*Shipbuilding.*) A sharp iron wedge used by calkers to force the planks apart temporarily, to admit the oakum.

Re-en'ter-ing. 1. (*Calico-printing.*) A term in the *hand-block* calico-printing applied to the secondary and subsequent colors, which are adapted to their proper place in the pattern on the cloth by means of pin-points. These are the equivalents of the register-points of the chromo-lithographic process or the typographic printing in colors. Also known as *grounding-in.*

2. (*Engraving.*) The deepening of lines by a graver, either in repairing a plate or for perfecting an etching.

Re-en'ter-ing-an'gle. (*Fortification, etc.*) An angle pointing inward (*a*), as in a *redoubt,* or at the junction of the *flanks* of a *bastion* with the *curtain.*

Fig. 4226.



Reëntering-Angles.

Re-fin'er-y. An apparatus for removing impurities or crudities from metals, spirits, petroleum, sugar, and what not.

The term is a general one, and with metals may include *reducing*-furnaces of various kinds. Also *roasting, decarbonizing,* and *desulphurizing* furnaces, *Bessemer processes,* etc. (which see). See also MALLEABLE IRON, page 1378.

See also SUGAR-MACHINERY.

With liquors, the term includes apparatus and machinery for rectifying and ageing liquors.

With petroleum, it includes apparatus for removing the various crudities which are in the raw product.

Re-fin'ing. The process of freeing metals, liquids, or other substances from impurities or crudities which impair their quality or unfit them for their appropriate uses.

1. Liquids are, in some cases, refined by adding soluble substances which entangle the foreign matters, and sink to the bottom, as with wine and cider. This is termed *fining*. In other cases, the refining is by chemicals which combine with the impurities and form a precipitate.

Sometimes standing a length of time suffices to effect the separation, the supernatant liquid being decanted.

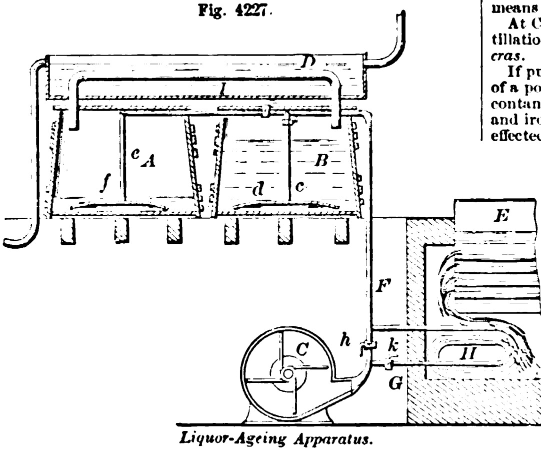
2. Saltpeter is refined by dissolving it in hot water until the water is saturated with salt. On cooling, the salt is deposited in a comparatively pure state.

3. Vinegar is refined by passing it through a filter to separate the mucilaginous matter. See RAPE.

4. Alcoholic spirits and liquids generally are refined by successive distillations. (See RECTIFICATION; STILL.) The same process is applicable to mercury, sulphur, and other substances, which may be volatilized at a high temperature and afterward condensed.

In one form of apparatus for refining and ageing liquors air from a blower *C* is heated in a coil *H* communicating with the pipe *F*, which has two branches *c c* extending downward through a disk near the bottom of the tubs *A B*. The liquor in the tub *B* is first heated to the temperature of 90°, and agitated by air passing from the coil *H* through the pipes *F c*, and rising from beneath the disk *d*, the cock *k* is closed and *h* opened, and cool air forced in through the pipe *F*. These processes are continued for the space of about a month, or until the desired result is attained. The air and alcoholic vapors pass over from *B* to *A* through the condensing-pipe *I* in the water-chamber *D*, the air being discharged from *A* through an aperture above.

Fig. 4227.



Liquor-Ageing Apparatus.

5. Petroleum is refined by treatment with sulphuric acid and by distillation.

6. The process of cupellation (see CUPEL) is largely employed for refining silver. In this, lead, already in combination with or added to the silver, is oxidized by heat and absorbed in a porous cup, taking with it most of the other impurities which are not previously expelled by the heat.

7. Gold is refined by cupellation and by *parting*, that is, dissolving in nitric acid. See PARTING; GOLD.

8. Iron is refined in the furnace and by *puddling*. See IRON; REFINING-FURNACE; PUDDLING; BESSEMER-PROCESS.

Re-fin'ing-fur'nace. (*Metallurgy.*) The furnace in which metals undergo a process of purification and separation from the impurities with which they are usually contaminated, and are rendered fit for use in the arts. In some cases the metal is reduced from the ore and refined by one continuous operation; in others, two or more are required.

The art of refining gold, silver, iron, tin, and copper was practiced previous to times of which we have any authentic history, implements of bronze and copper and ornaments of the precious metals being found among other relics of the prehistoric age, both in the Old and New Worlds.

In ancient times, the precious metals were refined by successive reheatings.

"Silver tried in a furnace of earth, purified seven times." — Psalm xii. 6.

"They gather silver, and brass, and iron, and lead, and tin, into the midst of the furnace to blow the fire upon it, to melt it." — Ezekiel xxii. 20.

From the former of these passages we may infer that a high degree of purity was attained by seven successive refinings. Purifying the precious metals and then reducing their standard by means of alloying does not appear to have been generally practiced, and is not to this day in the East.

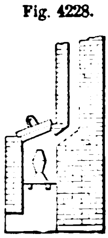
At Freiburg, Saxony, silver amalgamated by the barrel process is, after distillation, refined in crucibles, previously brought to a red heat. The silver is gradually introduced in lumps, and when fused strewn with powdered charcoal, and the crucible covered with an iron plate. After the lapse of a few minutes the impurities which had risen to the surface, together with the unconsumed charcoal, are skimmed off, more charcoal added, and the process repeated, occasionally stirring the molten metal, until its surface becomes bright and clean. When the process is complete, the silver should be malleable and dissolve completely in nitric acid. It is afterward cast into hemispherical ingots. The dust from the furnace flues is, after being sifted, mixed with and treated as ordinary silver ore. The slags and sweepings from the various melting operations are crushed and afterward fused with carbonate of soda and niter, by which means the silver is obtained in the metallic state.

At Constante, Spain, the porous silver obtained from the distillation of amalgam is melted in a species of cupola called a *cras*.

If pure, a loss of silver is entailed by exposing it to the action of a powerful blast; but if, as is generally the case, the metal is contaminated by impurities, such as lead, sulphur, antimony, and iron, which impair its malleability, their removal is readily effected by this apparatus.

Fig. 4228 is a section of a furnace for refining metals in pots. It is lined with the most refractory fire-brick, and has an opening of some 12 or 15 inches diameter, protected by a cover at top, through which the crucibles are introduced and the operation attended to. The grate-bars are removable, and, when required, an artificial blast is introduced beneath them by pipes.

Fig. 4228.



Refining-Furnace.

The operation of *refining* cast-iron consists in exposing it to heat and agents by which the carbon, silicon, and other extraneous matters are oxidized and removed. The pig-iron is either subjected to a preliminary purification in a *refining-furnace* or on a *hearth*, and the operation completed in a *puddling-furnace* (the English method), or it is effected in one operation in a puddling-furnace by an operation termed *boiling* (the American method). See PUDDLING.

When the operation is an intermediate one, the partially refined metal is run from the hearth into a bed, quenched with water, and broken with sledges to enable it to be handled into the puddling-furnace.

The bed of the refining-furnace is small, and the hollow boshes are of cast-iron, through which water flows, to resist the influence of the fire upon the sides of the chamber. Blasts of air are admitted through tuyeres, and the process consists in exposing the molten iron to the oxygen of the air, so as to burn away a part of the carbon and also remove certain noxious matters with which the iron is combined. The iron is then run into molds.

Lewis's refining reverberatory-furnace is thus worked. The fire of pitcoal is made on the grate bars, and when a melting heat is attained, the door of the iron-chamber is opened, and the basin occupying the middle of the floor is covered with a bushel of charcoal laid over a stratum of silicious sand, previously introduced. A bushel of hammer or forge cinder and then a ton of pig-metal is laid around the basin, which is about 10 inches deep, a space being left between the pigs so as to allow full access to the flame. The door of the iron-chamber is closed, and the fire pushed until the iron is about to melt. The iron is then dragged by a *rabble* into the basin, and the molten surface covered with a bushel of charcoal. The fire is kept up and the metal frequently stirred. When the decarbonization has proceeded to a sufficient degree, the metal is run off.

The consumption is said to be 15 to 18 bushels of pitcoal, 2 bushels of charcoal, making a ton of refined from 22 cwt. of pig metal.

The fluid iron from the blast-furnace is sometimes transferred direct to the refinery, thus saving the time and fuel required for remelting the pig-metal.

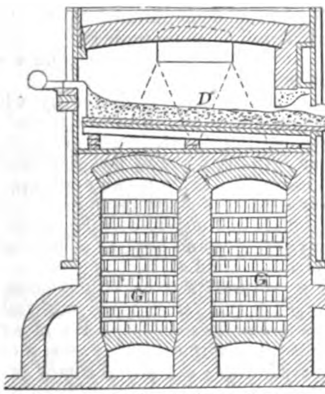
Various fluxes have been patented or proposed for assisting the process.

Hampton, 1856, slakes quicklime with a solution of alkali or alkaline salt. Du Motay and Fontaine use scoriæ from the puddling-furnace, oxides of iron and alkaline silicates or carbonates; Sanderson, 1855, uses substances containing oxygen or other element, by which silicium, aluminium, etc., are removed. Blackwell proposed remelting in a cupola furnace alone, or with the addition of substances containing nearly pure iron oxides.

Nasmyth and others have employed steam passed through or caused to impinge upon the molten metal in a state of ebullition. Bessemer, in 1855, patented a process of this kind.

In Martin's furnace (French), pig-iron is fused and maintained at a temperature of 1,600° to 2,000° C. on the hearth *D* of a reverberatory-furnace having a

Fig. 4229.



Martin's Refining-Furnace.

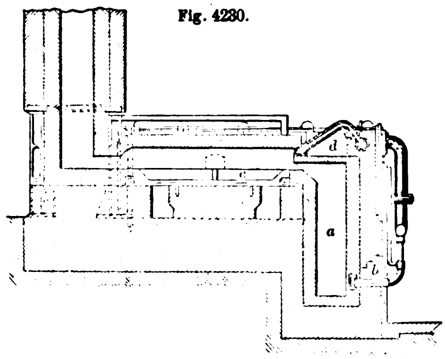
covering of refractory sand and heated by means of a Siemens regenerator *G G*. Ore, or puddled steel, or old iron in small pieces, is thrown in, and manganiferous iron afterward added.

At some of the Pittsburg iron-works the metal is refined by mechanically mingling pulverized oxides of iron with the molten crude metal direct from the blast-furnace. This is run from the furnace into a large kettle, and thence poured into a revolving circular trough. Pulverized ore from a hopper descends and covers the melted metal as fast as it runs into the trough, whose continuous rotation causes the formation of alternate thin layers of the crude metal and ore which combine to form malleable iron. Lake Superior, Champlain, or Iron Mountain ore is employed.

Chlorine, hydrogen, and coal gas, the oxides of manganese and zinc, etc., have also been employed.

In Eck's furnace (German), coal gas is used. A quantity of coal is introduced into the generator *a* through an opening in the bottom, and when this has become fully ignited the opening is bricked up and the generator filled with coal from above; a moderate supply of air to support combustion is allowed to enter through the lower tuyeres *b*. When the refining-hearth *c* has become thoroughly dried and heated, about 40 cwt. of iron

Fig. 4230.



Gas Reverberatory-Furnace.

is distributed over the hearth, so as to expose as much surface as possible to the action of the flame. The fusion of the charge is effected in about three hours, the gas generator being always kept filled and the supply of air from the lower tuyeres diminished after each introduction of fresh coal, as the latter yields its gas more freely at first.

Air introduced through the upper tuyeres *d* effects the combustion of the gas as it passes from the generator on to the hearth. During the progress of fusion the metal is shifted, so that each part may in turn become exposed to the hottest portion of the blast, in the vicinity of the fire bridge.

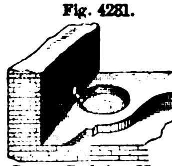
When all the iron is fused, about five pounds of limestone are thrown over its surface, in order to convert the dross into fusible slag.

The blast from two side tuyeres is now directed upon the fused metal, blowing aside the slag and creating currents in the mass, so that a fresh surface is continually exposed: the operation is assisted by stirring with an iron rod, and fresh limestone occasionally added, the total amount used being about 1 per cent of the crude metal.

The iron is withdrawn through a tap-hole at the side of the furnace, the opposite tuyere being employed to aid in forcing it out. The duration of the treatment after fusion varies from 2½ to 5 hours, the latter time being required to produce pure white iron.

Re-fin'ing-hearth. The copper-refining hearth has a hemispherical crucible of about 16 inches diameter, and lined with a puddle of 2 parts charcoal, 1 part clay. It is partly surrounded by a raised border, the open portion of which has a door to prevent the escape of the fuel. The lining is renewed before each operation, and is burnt on by a fire ignited in the crucible before charging with the fresh charcoal and pieces of black copper. The blast being let on and the copper fused, metal and fuel are added from time to time, the scoriæ being let off by a side-channel.

Fig. 4231.



Copper-Refining Hearth.

Sulphurous acid escapes and other volatile ingredients, if present. When the operation is complete the workman stops the blast, throws water on the hearth, rakes back the scoriæ with his *rabble*, and throws water on the metal, which congeals a thick film on the surface; this is of a red color, and is known as a *rosette*, the metal being *rose-copper*, and obtained by successive *quenching* and removal of the *rosettes*.

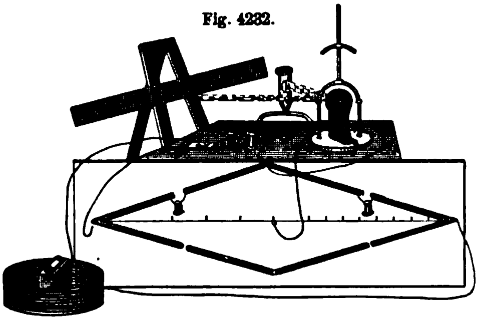
A farther refining, to reduce the suboxide of copper and obtain malleable metal, is conducted in a crucible covered with small charcoal and placed in a hearth similar to the foregoing.

Re-flect'ing-cir'cle. (*Optics.*) An instrument for measuring altitudes and angular distances, invented by Mayer about 1744, and afterward improved by Borda and Troughton.

In principle and construction it is similar to the SEXTANT (which see), the graduations, however, being continued completely round the limb of the circle. Troughton's has three arms radiating from the center at angular distances of 120° apart, each provided with a vernier, so that each angle measured is derived from the mean of three readings at opposite points of the arc, which tends to correct errors of centering and graduation. See REPEATING-CIRCLE.

Re-flect'ing-gal'va-nom'e-ter. Sir William Thomson's reflecting-galvanometer consists of a very small magnet, made of a piece of watch-spring, suspended between two flat bobbins of fine insulated copper wire. The magnet carries a very small concave mirror, which is adjusted by means of a directing-magnet to throw the rays of light issuing from a lamp and reflected from the mirror upon the zero of a horizontal graduated scale when no current is passing or when two equal and opposite currents neutralize each other. In any other case the vibrations of the magnet cause the image to be deflected to the right or left of zero by an amount proportional to the force and duration of the current.

Fig. 4232.



Thomson's Reflecting-Galvanometer.

The figure shows the instrument employed in determining resistances in connection with Wheatstone's *bridge*.

Re-flect'ing-lev'el. The reflecting-level represents the object as reflected upon a long surface of water in an inverted position. Invented by Mariotti.

Another kind consists of a polished metallic mirror, placed at a small distance before the object-glass of a telescope, suspended perpendicularly. This mirror being set at an angle of 45°, the perpendicular line of the telescope will become a horizontal line, that is, a line of level. Invented by Cassini. See LEVEL.

Re-flect'ing-mi'cro-scope. A form of microscope first proposed by Newton, in which the image formed by a small concave speculum may be viewed either by the naked eye or through an eye-piece. Owing to the difficulty of illuminating the object, it was long disused, but has been revived by Professor Amici, who places the object outside of the tube of the microscope, and reflects its image to the speculum by means of a plane mirror, inclined at an angle of 45° to the axis of the former.

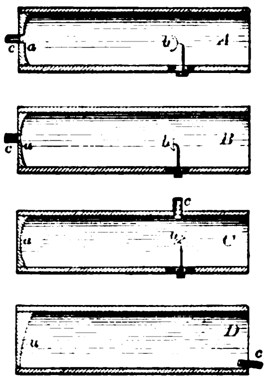
Re-flect'ing-tel'e-scope. A telescope in which the rays are received upon an object-mirror and conveyed to a focus, at which the image is viewed by an eye-piece.

There are four principal varieties: —

A Gregorian. *C* Newtonian.
B Cassegrainian. *D* Herschelian.

The Gregorian telescope (*A*, Fig. 4233) was invented by Gregory, and described by him in his *Optica Promota*, 1663.

Fig. 4233.



Reflecting-Telescopes.

The object-mirror is perforated in the axis, and the rays of light, being reflected from the surface of *a*, cross each other in the focus, where they form an inverted image, and are then intercepted by a small concave mirror *b*, which causes them again to converge to a focus, where they form a direct image viewed by the eye-piece *c*, screwed into the tube behind *a*.

The Cassegrainian telescope (*B*) differs from the Gregorian in having the small mirror *b* convex, but not sufficiently so to render the rays reflected from *a* divergent; they are therefore brought to a focus just in front of the large speculum, forming an inverted image which is viewed by the eye-tube.

In the Newtonian form (*C*), invented by Sir Isaac Newton, 1669, the rays falling on the concave speculum *a* are intercepted before being converged to a focus by the small plane mirror *b*, placed diagonally in the main tube, which reflects the image to the eye-piece inserted in the side of the tube. The small mirror *b* may be caused to approach or recede from the large speculum by means of a sliding device on which the wire supporting it is mounted.

In the Herschelian or front-view telescope (*D*), the open end of the tube is directed toward the object to which the observer turns his back. The small mirror is dispensed with, the image formed by the large mirror being viewed directly through the eye-piece. Less light is lost by this arrangement than where two mirrors are employed.

Re-flect'or. 1. (*Optics.*) A device by which the rays proceeding from a luminous or a heated object are thrown back or diverted in a given direction. A mirror. The latter term, however, appears to be less comprehensive, being usually only applied to such surfaces as afford definite images and colors, while a reflector may not merely be used for throwing back the rays of light and heat, or of heat only, but also the waves of sound.

The reflecting surface may be either plane or curved. In practice it is often made spherical or parabolic. The former does not bring the rays to a true focus, but is easily formed, and is consequently generally employed where extreme accuracy is not sought for.

"The surfaces formed by the revolution of the ellipse, parabola, and hyperbola are such that the first accurately reflects diverged rays to a focus, the second parallel rays, and the third divergent rays." — BRANDE.

The material should be as smooth and highly polished as possible. Sheet-tin is frequently used for common purposes, as for door or hall lamps, or those carried by vehicles, while for other purposes a more perfectly reflecting surface is employed, such as speculum metal or silver protected by glass. See SILVERING; PLATINIZING.

Silver is the most perfectly reflecting substance known, absorbing but 9 per cent of the incident rays, while speculum metal absorbs 37 per cent. Glass itself, owing to its property of totally reflect-

ing incident rays at a low angle, is used in certain cases.

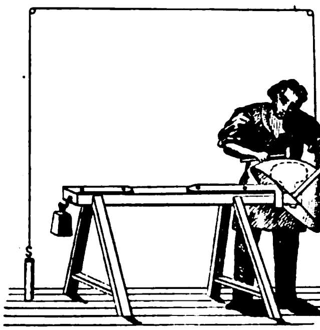
Reflectors with parabolic surfaces are employed for throwing the light emanating from objects placed in their foci in parallel straight lines to a great distance, and for converging the heat rays from a distant object, as the sun, to a focus, and also, in connection with eye-glasses, in the reflecting-telescope, which is itself often simply denominated a reflector. See REFLECTING-TELESCOPE; CATOPTRIC LIGHT; MIRROR; BURNING-GLASS.

The reflectors used with microscopes are various, according to the exigencies of the position, shortness of the focus, etc.

Under ILLUMINATOR are cited *Beck's, white-cloud, side-reflector, parabolic reflector, Lieberkuhn,* etc., — all forms of reflectors adapted to microscopes.

Paraboloidal reflectors were employed in the lighthouses at Bidstone and Hoylake, at the entrance of the Mersey, as early as 1763. These were of wood lined with mirror glass; smaller ones of tin were also employed. At present, lighthouse reflectors are made of copper heavily plated with silver. The proper curve is imparted by beating with mallets and hammers of various forms and materials; a bezel is formed around the rim, which is afterward stiffened by a metallic strap, and the interior surface polished with powder. Two ingots of pure silver and copper, of equal surface, weighing respectively 6 and 16 ounces, are tied together with wire, a flux of burnt borax and niter applied, and the ingots placed in a furnace. By repeated reheatings, rolling, and annealing, a plate 28 inches square is formed, which is then cut into a circular disk. A slight convexity is then formed at the back by beating with a round-faced boxwood mallet. The silvered side of the plate is placed on a slightly concave beechwood block and beaten from the edge gradually toward the center. The partially rounded disk is then placed concave side downward on a rounded steel former mounted on a horse, and beaten first with the peen and afterward with the face of the mallet until the proper form and size are nearly attained; it is next planished and afterward smoothed with a light hammer muffled with parchment at each end. To facilitate handling, the reflector is slung in a flexible frame counterbalanced by a weight suspended from a cord passing over pulleys. It is finally finished by carefully beating up all depressions, the accuracy of the work being continually tested by a gage or templet.

Fig. 4284.



Reflector-Making.

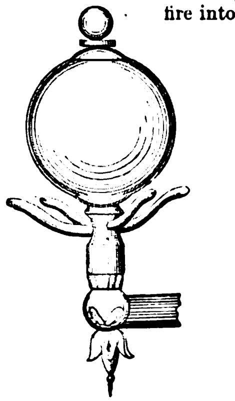
Fig. 4235 is a reflector for workshop and household purposes. It has a globular polished surface, so that the light of the several gas-jets by which it is surrounded may be equally diffused on every side.

Murch's reflector for lamps of street cars has a pair of parabolic reflectors *a a*, *b b*, joined at their apexes, where a portion of each is removed. At this central position, which is approximately at the foci of the reflectors, is a lamp *c*, whose beams are thus thrown in both directions in nearly horizontal beams of limited lateral divergence.

2. A short name for the REFLECTING-TELESCOPE (which see).

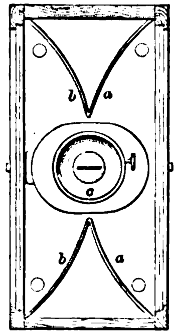
3. The reflector has also been extensively used for radiating the heat from an open fire into an apartment.

Fig. 4235.



Gas-Light Reflector.

Fig. 4236.



Street-Car Lamp-Reflectors.

Dr. Franklin and Count Rumford appear to have been the first who put forward intelligent ideas on this subject.

As early as 1795, a patent was taken out in England for a removable reflector, and in 1805, polished metallic reflectors were placed on each side of the fireplace, to be turned at any angle to reflect the heat of the fireplace into the room. In 1816, the fire-grate was inclosed in a hollow metallic globe opening in front of the grate. In 1852, the hearth, cheeks, and faces of the grate were made of polished steel. Several devices for radiating heat were patented in this year.

Sylvester's invention for this purpose is described as follows: The hearth is formed of a framework of hollow radiating metallic bars, diverging and fanlike in arrangement, upon the farthest end of which the fuel is supported. The air for combustion passes through the hollow bars to the fire, which also derives a supply in front in the usual way. The ends of the bars on which the fuel rests become intensely hot. The remaining portion or hearth from conduction becomes likewise heated, and radiates its warmth around. The fire, being situated upon the hearth, allows the greatest possible length of surface to the cheeks or sides of the stove, which are of polished metal, and contribute greatly to the amount of heat afforded by radiation. The smoke escapes through the apertures of a kind of louver at the back, and the ashes pass between the bars into a receptacle beneath.

Re-fract'ing-tel'e-scope. A telescope in which the rays are refracted by an object-glass, at whose focus they are viewed by an eye-piece. It is the ordinary form of telescope. See TELESCOPE; ASTRONOMICAL TELESCOPE; EQUATORIAL, TERRESTRIAL REFRACTING-TELESCOPE, etc.

The original form of the telescope, as used by Galileo, had a convex object-glass and a concave eye-glass.

Fig. 4237.

Galilean Telescope.

The rays converged by the object-glass *a* fall upon the double concave lens *b*, which intercepts them before they arrive at the principal focus, where they would make an inverted image. Being thus rendered parallel, they give a distinct vision to the eye at *c*.

The lens *b* is therefore placed between the object-glass and the image, and at a distance from the image equal to its principal focal distance. The magnifying power is equal to the focal length of the object-glass divided by the focal length of the eye-glass.

Re-frac'tion-cir'cle. (*Optics.*) The refraction-circle of the Washington Observatory was made by Ertel and Son, of Munich. The telescope has a clear aperture of 7 inches, and is $8\frac{1}{2}$ feet in length. It is supported in the middle of the axis between two piers, and it has two circles of 4 feet diameter, one on each end of the axis, divided on gold into arcs of

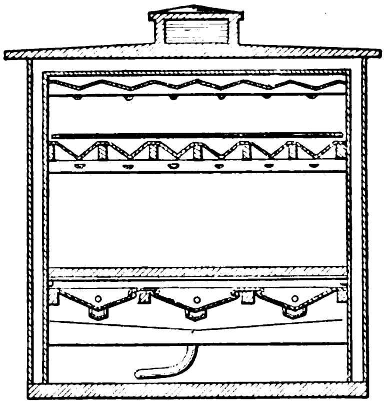
2′. Each circle is provided with six reading microscopes. See also TRANSIT-CIRCLE.

Re-fract′or. A refracting-telescope. See TELESCOPE.

Re-frac′to-ry. (*Pottery.*) A piece of ware covered with a vaporable flux and placed in a kiln, to communicate a glaze to the other articles; an operation termed *smearing.*

Re-frig′er-at′ing-cham′ber. An apartment for the storage of perishable provisions during warm weather. It is frequently a structure in connection with an ice-house. In the example, the ice is stored overhead and the meat or vegetables in the larger room beneath. The cool air descends by gravity and displaces the moist and warmer air, which ascends.

Fig. 4238.



Refrigerating-Chamber.

The moisture condenses upon the ceilings of the meat-chamber and the ice-chamber, which are formed of angularly corrugated metallic plates; and the drip from the salient angles is caught in troughs by which the liquid is conveyed to the exit-pipe.

Re-frig′er-a′tor. Refrigeration, natural or artificial, is used for keeping animal or vegetable substances by reducing the temperature below the point of fermentative disorganization. Such are fruit and meat cellars and cars.

Wort, mash, or beer coolers are of this class; also apparatus for reducing the temperature of wine must, the juice of sugar-cane or beets.

Saccharine juices and wines may be concentrated to a certain extent by freezing; the watery particles becoming congealed are removed, leaving the remainder of a greater strength.

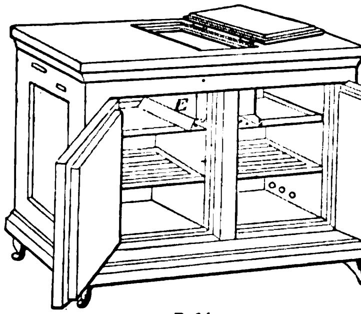
1. A *refrigerator* for cooling wort consists of a large shallow vat traversed by a continuous pipe, through which a stream of cold water is passed. The *wort* runs in one direction and the water in the other, so that the delivery end of the wort is exposed to the coolest part of the stream of water. See also LIQUID-COOLER; BEER-COOLER.

2. (*Steam.*) *a.* A casing with connecting-tubes, through which feed-water passes on its way to the boiler, and is warmed by the current of hot brine passing in the other direction, on the outside of the tubes. The hot brine, at a temperature of say 218° Fah., is that which has been removed from the boiler by the *brine-pump.* The term *refrigerator* is a misnomer. It should be called a feed-water *heater.* The latter name is applied to a somewhat similar arrangement in which the feed-water is heated by exhaust steam.

b. The chamber in one form of condenser, in which the injection-water (fresh) is cooled by a surface application of cold sea-water. See INJECTION-CONDENSER.

3. (*Domestic.*) A chest or closet holding a supply

Fig. 4239.

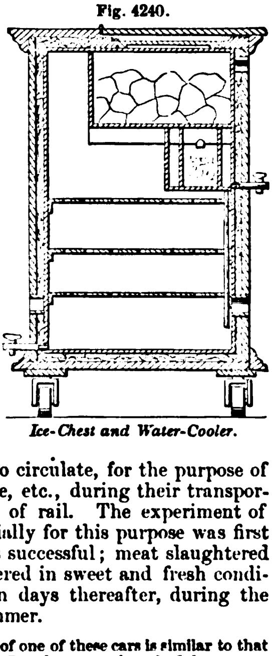


Refrigerator.

of ice to cool provisions and keep them from spoiling in warm weather. In the example, a vertical channel divides the refrigerator into two separate chambers, each partitioned into three receptacles. Air circulates between the interior and exterior walls. Two front doors and one on top afford access. *E* is the ice-box which cools the air in each of the side chambers.

Fig. 4240 shows a chest whose melting ice passes through a filter into a chamber, whence it is drawn as ice-water. Drip and water of condensation are withdrawn at the lower faucet.

Fig. 4240.



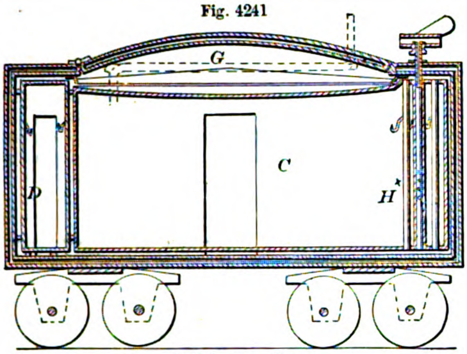
Ice-Chest and Water-Cooler.

Re-frig′er-a′tor-car. (*Railway.*) A car through which a current of artificially cooled air is caused to circulate, for the purpose of preserving meats, game, etc., during their transportation over long lines of rail. The experiment of constructing cars specially for this purpose was first tried in 1867, and was successful; meat slaughtered in Illinois being delivered in sweet and fresh condition at New York ten days thereafter, during the hottest part of the summer.

The external appearance of one of these cars is similar to that of an ordinary freight-car. In a box at each end of the car are blocks of ice placed on a grate in such a manner as to allow a current of cold air to circulate constantly through a flue near the top of the car, over the ice, down to the floor, then up among the poultry, mutton, and beef, and again around through the flue and over the ice. The circulation of air is effected by a large ventilator-wheel placed horizontally at the top of the car near the middle. The forward movement of the car keeps this wheel in motion, which, in turn, produces a current of cold air constantly from the ice to the meat in one direction, and from the meat to the ice in another direction. By this means, every piece of meat is kept at a uniform temperature of about 40° Fah. The cars are built double all around, with inside double doors, filled in with charcoal, and have a capacity for holding two tons of ice. At the principal stations they are carefully examined, and ice added whenever it is deemed necessary.

Wood's has a plurality of chambers *C D* for through and way freights; the ice-box *G* is covered by a hinged door, and air is, by means of the car-ventilator, caused to circulate through the

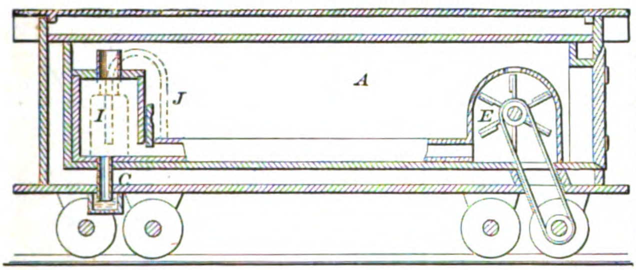
Fig. 4241



Refrigerator-Car.

open spaces between them and the walls of the car. Hollow pillars *H* carry hooks from which the meat is suspended.

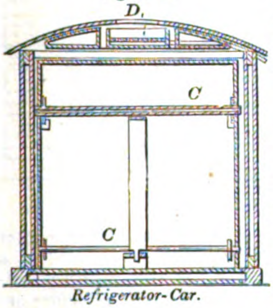
Fig. 4242.



Refrigerator-Car.

In Bray's, the refrigerating-chamber *A* is surrounded by an air-space. Air is forced by the blower *E* into the chamber through an ice-box *I*, which may contain a case in which is a freezing mixture, in this case passing through the pipe *J*. The water is drawn off by a trap *C*.

Fig. 4243.



Refrigerator-Car.

McCrea's has an ice-box *D* at top. The cooled air by its superior density descends between the inner and outer walls of the car and circulates through the pipes *C C*, passing from side to side, thus refrigerating the air of the chamber, which is at the same time kept comparatively dry, as the vapor-laden air from the refrigerator does not enter the chamber.

Re-frig'er-a-to-ry. A chamber, vessel, or pipe in which a cooling is effected, as, —

1. The worm of a still. See STILL.

2. (*Steam-engine.*) *a.* The condenser of an engine. See CONDENSER.

b. A form of heater in which feed-water extracts a portion of heat from the hot water driven out of the boiler by the brine-pump.

3. The worm or chamber of a liquid-cooler for beer, wort, wash, etc. See LIQUID-COOLER; BEER-COOLER.

4. The chamber in which ice is artificially formed. See ICE-MAKING MACHINE.

5. (*Domestic.*) The chamber in which provisions are kept by exposure to a cool atmosphere. See PRESERVING FOOD; REFRIGERATOR; ICE-CHEST; ICE-SAFE, etc.

Re-fus'al. (*Hydraulic Engineering.*) The resistance to farther driving offered by a pile. For instance, the refusal of a pile intended to support 13½ tons may be taken at 10 blows of a ram of 1,350 pounds, falling 12 feet and depressing the pile .8 of an inch at each stroke.

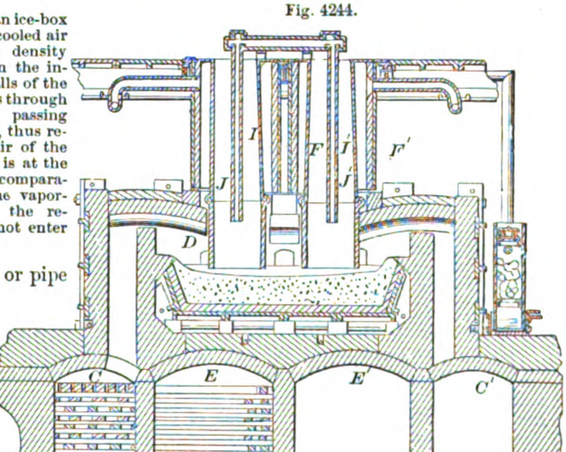
Re-gen'er-at'ing-fur'nace. A furnace in which the outgoing heated volatile products are caused to heat a mass of material, which, when the direction of the current is reversed, heats the incoming air or gas with which the furnace is supplied.

In Siemens's apparatus both heated vapor, or vapor and steam, and atmospheric air are passed through the regenerators and consumed in the furnace. It has of late been extensively employed for glass, pottery, and metal-reducing furnaces, and in the production of steel, either directly from the ore or from iron.

Fig. 4244 illustrates an apparatus particularly designed for making steel from the ore. *C C'*, *E E'*, are the regenerators. These are filled in with fire-brick, so laid as to leave a large number of passages between them, through which the air or gas may circulate on its passage to and from the furnace.

Heated gas from the *producer*, a furnace in which gases are generated by the combustion of coal, and into which steam may be injected to form hydrogen gas by its decomposition, passes through a pipe to the generator *C* at the same time that a current of hot air is passing through the generator *E*. These are conducted to the furnace *D* by pipes *J J'* in the cylinders *I I'*, through which the mixed ores, charcoal, and flux, if any, are introduced. A quantity of pig-metal is placed in the bottom of the furnace, and the reduced ore from the cylinders *I I'* is forced downward and mixed with it, and spiegeleisen added if required. The mingled air and gas, having effected the work of reduction, pass out through the generators *C' E'*, and are conducted away to the chimney. Chambers *F'* on either side of the furnace also communicate with it and with the chimney. When the generators have become heated to a thoroughly white heat, the currents are, by means of a reversing valve, diverted so as to flow in the opposite direction, entering through the generators

Fig. 4244.



Metallurgical Furnace.

C' E' and passing out through *C E*. The products of combustion are thus alternately heated by each set, and cooled by the other, to which they impart their heat, so that when discharged

into the chimney they are at a comparatively low temperature.

Re-gen'er-a-tor. A device to abstract the head from an escaping volume of air or gas, in order that it may be imparted to a body of incoming air. The object is economy of fuel by conservation of heat.

An illustration of this may be found in the air-engine of Glazebrook, English patent, 1797, and in Stirling's English patent, 1816. The latter had the metallic sieves of wire gauze afterward adopted by Ericsson. Their use in this connection is a fallacy. See AIR-ENGINE. See also REGENERATING-FURNACE.

Reg'is-ter. 1. A device for automatically indicating the number of revolutions made or amount of work done by machinery, or recording steam, air, or water pressure, or other data, by means of apparatus deriving motion from the object or objects whose force, distance, velocity, direction, elevation, or numerical amount it is desired to ascertain.

There are various special appliances of this kind, each particularly adapted for the peculiar operation which is to be investigated; many depending on the action of clock-work mechanism, which indicates results on dials, but others, as in registering meteorological instruments, having means for recording varying conditions, as with the *anemometer*, *barograph*, etc.

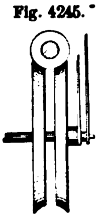
As counters, are the various devices known as ARITHMOMETERS (which see). These, in their primary intention as calculating instruments, are not mere registers, but they are attached to other devices to keep count of motions, and so become *registers* or *recorders*. Instances may be found in the recording devices of

Billiard-registers.	Steam-engine registers.
Counting-registers.	Street-car registers.
Furnace-registers.	Telegraph-registers.
Granary-registers.	Time-registers.
Measuring-registers.	Ventilation-registers.
Passenger-registers.	Watchman's registers.
Printing-press registers.	Weighing-registers
Speed-recorders.	See also list under METERS.

The device so common in arithmometers, calculating-machines, and registers, consisting of a series of wheels numbered 0 to 9, and gearing into each other, so as respectively to represent units, tens, hundreds, etc., was invented by Pascal when 19 years of age (1650).

Among the applications of gearing to produce extremely slow motions which may be utilized in counting, and are, therefore, applicable to registers, may be cited epicyclic and differential gears.

Fig. 4245.



Differential Counter.

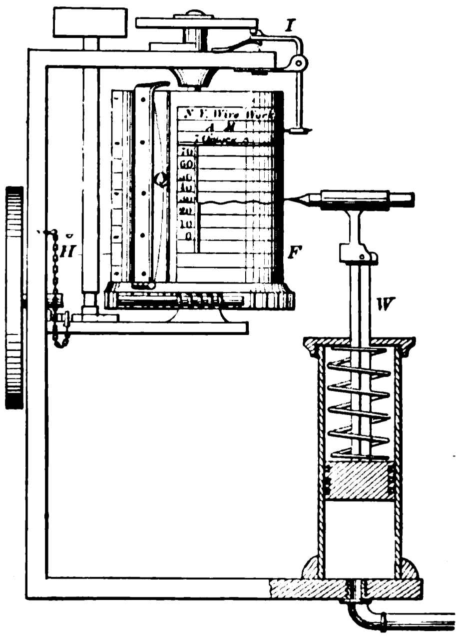
The matter as to the former has been considered at as full a length as admissible under EPICYCLIC TRAINS (which see).

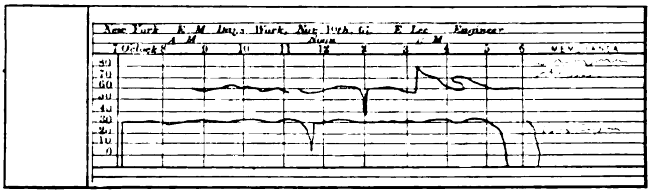
A differential device is shown in Fig. 4245. Two worm-wheels of equal diameter (teeth omitted in the illustration) have respectively 100 and 101 teeth, and are in gear with the same worm. One wheel gains 1 revolution over the other during 10,100 revolutions of the worm. Each wheel has an index-finger, and the angular distance between them on a graduated dial will form a register.

Watt first applied a *register* to the steam-engine to count the strokes.

The term *register* is also applied to a *recording indicator* (see INDICATOR), as in the example (Fig. 4246), in which an endless roll of paper wound on to the upright cylinder *F* and held thereto by a pad *Q* is uniformly drawn off therefrom by the roller *H* rotated by connection with the engine. Clock-work mechanism causes a point at the lower end of the lever *I* to puncture the paper at hourly intervals. The paper being previously ruled with vertical hour-lines with intervals corresponding to a given rate of speed, the relation of the punctures to these lines indicates whether the engine has been run at the proper ve-

Fig. 4246.





Clarke and Edson's Steam-Pressure Register.

locity. The rate of pressure is recorded by a marker on the piston-rod *W* of a cylinder connected by a pipe with the steam-chest. For this purpose horizontal lines corresponding to different pressures are ruled on the cylinder.

The rolling-mills in the United States Mint at Philadelphia are provided with dials having a hand indicating the exact distance between the rolls. It is the invention of Franklin Peale. A crank on the arbor of the index-hand is the means of adjusting the *set* of the rolls, and certain points on the graduated dial indicate the distance for half-dimes, dimes, quarters, gold dollars, eagles, and all the varieties of coin which are made at the mint. The process of rolling is called *breaking down*, and the ultimate size is obtained by repeated rolling, perhaps ten times for gold and eight times for silver. The register is set to a certain mark for each thickness, to which the bar is reduced during the successive rollings.

2. (*Printing.*) Agreement of two printed forms to be applied to the same sheet, either on the same or the respective sides thereof.

The former is used in chromatic printing, where a number of colors are laid on consecutively.

The latter is found in book and newspaper printing, where the correspondence of pages or columns on the respective sides is required.

The registering apparatus of the printing-press consists of points which pass through the paper and serve as guides for relaying the paper on the tympan in printing a second color, or as guides in folding.

3. (*Heating.*) A sliding plate acting as a damper or valve to close or open an aperture for the passage of air. As, —

a. The draft-regulating plate of a stove or furnace. Sometimes connected with a pivoted plate in the chimney, so as to be self-operating. The damper-plate of a locomotive engine.

b. A perforated plate governing the opening into a duct which admits warm air into a room for heat, or fresh air for ventilation, or which allows foul air to escape.

Savot in his work "L'Architecture François des Bastimens particuliers," Paris, 1624, is the first to mention the *register-plate.* He credits the invention to the English, saying that it is customary in England when a brazier full of fuel is well lighted, and has ceased to smoke, to pass an iron plate (*porte de fer legère*) across the chimney, and so confine the heat to the room. This plate is the same as the *damper*, but the term *register* is the older.

In the furnaces of the alchemists, openings left for the supply of air, and which could be contracted or closed by pieces of clay, were termed *registers.*

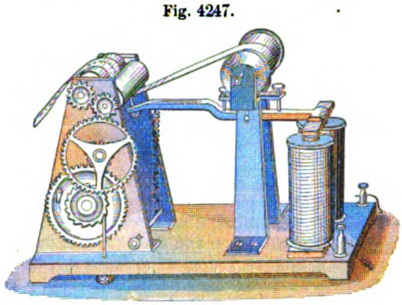
Ben Jonson says: —

"Look well to the register,
And let your heat still lessen by degrees."

4. (*Music.*) A stop of an organ.

5. (*Telegraphy.*) The part of a telegraph apparatus used for recording upon a strip of paper the message received. It consists of a clock-work, which moves the strip of paper at a uniform speed in contiguity to the *stylus* or marking-pen, whose movements are controlled by the electrical current. In

Fig. 4247.



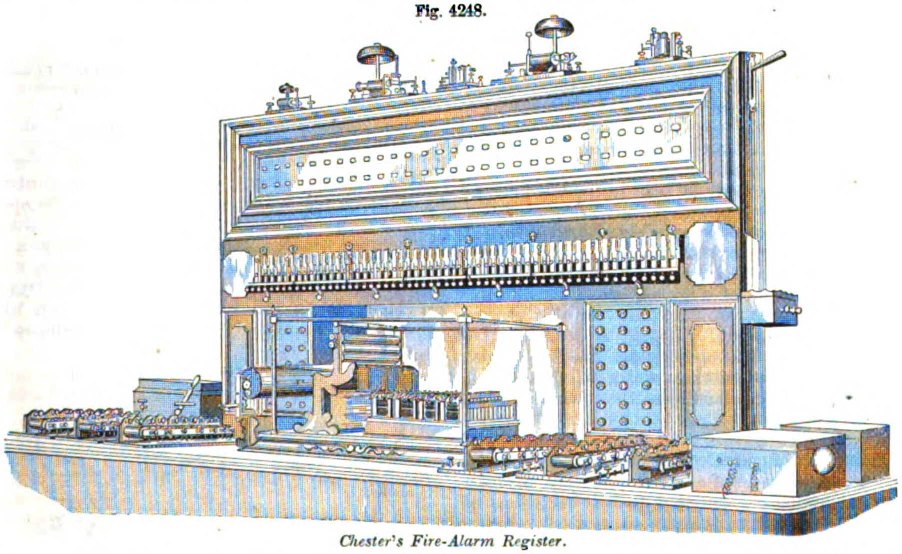
Morse Register.

the ordinary Morse apparatus this stylus is simply a sharp metallic point on the end of the armature lever, which embosses the character on the strip of paper on being brought in contact therewith.

An inking stylus or an inking roller is sometimes used in lieu of a plain stylus.

The fire-alarm telegraph register records all the alarms and tests which are sent into the central office. The line currents from the stations are received through a series of fifty-six relay magnets, which also act upon annunciators indicating the number of the station turned in.

Fig. 4248.

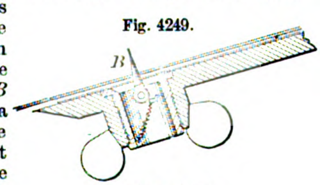


Chester's Fire-Alarm Register.

When a signal is struck at a street box the circuit is broken, the magnet appropriate to that station drops, operating a lever which throws down the annunciator corresponding to that number, rings a bell, sets in motion the register train, carrying forward a broad, endless roll of paper, and by means of a pen, of which there are fifty-six, actuated by as many magnets, imprints the signal on the endless roll. The condition of the line is also hourly tested through this apparatus.

Reg'is-ter-point. (*Printing.*) A device for puncturing or holding a sheet of paper, serving as a guide in laying on the sheet, so that the impressions on each side shall accurately correspond or *register* correctly. One is placed on each side of the table. In the example, the pivoted pointers *B* are snapped by a spring into the sheet and hold it in position till the nippers of the cyl-

Fig. 4249.



Register-Point.

inder draw the sheet, when the point automatically retires.

Reg'is-ter-ing-ther-mom'e-ter. A thermometer in which the column of mercury moves a glass or porcelain bar and leaves it at the maximum or minimum point which is reached by it between observations. See THERMOMETER; MAXIMUM THERMOMETER; MINIMUM THERMOMETER.

Reg'let. 1. (*Printing.*) A strip of wood or metal with parallel sides and of the hight of a *quadrat,* and used for separating pages in the chase, etc.

They are sometimes made type-high to form black borders.

2. (*Architecture.*) A flat, narrow molding, employed to separate panels or other members; or to form knots, frets, and similar ornaments.

Reg'let-plane. A plane used in making reglets or printer's furniture for spacing lines. The adjustable *fences* are screwed fast to the body of the plane, and project from the sole a distance equal to the hight of a *quadrat,* so that when the fences rest on the bench the plane-bit will cut no longer. See cut under ROUNDING-PLANE.

Re-grat'ing. (*Masonry.*) Taking off the surface of an old hewn-stone wall in order to whiten it and make it look fresh again.

Reg'u-la. (*Architecture.*) A band below the tænia of the Doric epistylium, extending the width of the triglyph, and having six guttæ depending from it. It also signifies the space between two adjoining canals of the triglyphs.

Reg'u-lat'ing-screw. A screw used for determining a motion.

The motion of the roller of a copperplate press, upward from the bed, is regulated by screws which bear upon the journal-boxes.

The upper roll of a bar, sheet, or other iron mill is similarly arranged.

The motions of the slides and moving parts of machinery are sometimes regulated by screws, which act as *stops* or *slides.*

Reg'u-la'tor. A mechanical contrivance for equalizing motion.

The generic name may be held to include *governors, thermostats, gas-regulators, fly-wheels, flyers, dampers, pendulums, balance-wheels, throttle-valves, compensation arrangements in timepieces,* etc. These will be found under their specific heads.

1. The brake-band of a crab or crane.

2. (*Steam-engine.*) *a.* The governor of a steam-engine. See GOVERNOR.

b. The *cataract* of a steam-engine. See CATARACT.

c. A device for admitting steam in regulatable quantity to the valve-chamber of the steam-cylinder. See REGULATOR-BOX.

3. (*Furnace.*) A device for regulating access of air to a stove or furnace. Known as a *draft-regulator.* It may consist of a *register, damper,* or *door.* Automatic appliances actuated by the variations of heat are THERMOSTATS (which see).

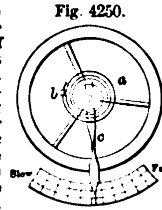
4. (*Horology.*) *a.* A clock keeping accurate time, used for regulating other timepieces.

b. The device by which the pendulum-bob is elevated or depressed.

c. The fly of the striking part of a clock or musical box.

d. An arm which determines the length of the balance (or hair) spring of a watch. By shortening the length of spring involved in the action, the rate of motion is increased, and conversely. On the under side of the arm are two pins, which embrace the spring, the center of motion of the arm being concentric with the arbor of the balance. As the arm is rotated, the pins slip on the spring, the extent of movement of the arm being indicated by a pointer on a graduated arc.

Fig. 4250.



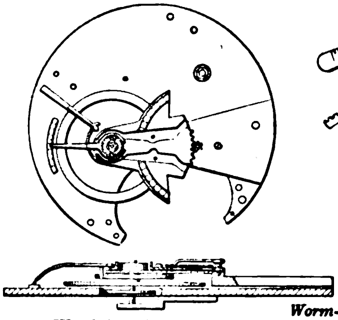
Watch-Regulator.

The balance-spring *a* is attached at its outer end to a stud *b* on the watch-plate, and at its inner end to the staff of the balance. The balance pulsates in one direction under the influence of the main-spring communicated through the train, and is returned by the recoil of the spring after passing the point at which these forces are in equilibrio. The duration of the pulsation is determined by the length of the hair-spring *a*, a longer spring allowing a longer movement of the balance. The lever *c* has two curb-pins, between which the hair-spring passes, and its activity is checked at this point. By moving the lever to the right, the effective length of the spring is decreased, and the pulsations are shortened, the balance moving quicker. When the watch is *too* fast, motion in the other direction corrects it.

Means have been employed for the more delicate adjustment of this arm, other than by a mere push. Among these are the worm-wheel and rack, as in Fig. 4252.

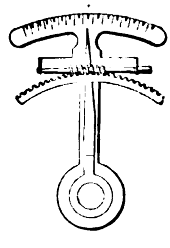
In Fig. 4251, the pointer which carries the pins embracing the hair-spring is connected to a bar having a segmental rack, actuated by a small cog-wheel; the shaft of the latter carries a pointer, by moving which a delicate adjustment is obtained.

Fig 4251.



Watch-Regulator.

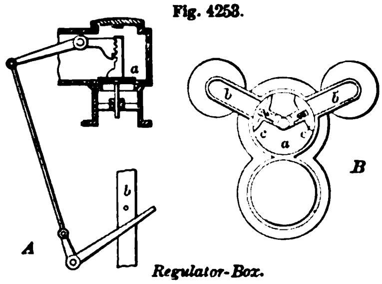
Fig. 4252.



Worm-Wheel Adjustment for Regulator.

Reg'u-la'tor-box. A valve-motion contrived by Watt for his double-action, condensing pumping-engines (*A*). A spindle passes through one side of the box, on which a toothed sector moves as a center, working a rack fixed to a brass valve *a*, which is accurately ground to its seat. The plug-tree *b* is provided with a pin which trips the lever, whose upper arm is connected to the toothed sector, so that the reciprocations of the plug-tree open and shut the valve.

Fig. 4253.



Regulator-Box.

In locomotives (see *B*) a pipe conducts steam from the steam-drum to the regulator *a* connected with the cylinders by two pipes *b b'*, which are opened or closed by the valves *c c'*, operated by a rod running longitudinally of the engine and turned by a lever within reach of the engineer.

The *regulator-cock* admits oil or tallow for lubricating the faces of the regulator.

Reg'u-lus. (*Metallurgy.*) The relatively pure metal which sinks to the bottom of a crucible or a furnace in the fusing and refining process. The slag or scoriæ floats upon it, and is skimmed off or conducted in another direction.

The term is not now often used, except when applied to antimony.

Re-heat'ing-fur'nace. (*Metallurgy.*) A reverberatory-furnace, resembling a puddling-furnace, in which blooms or piles of sheared or scrap iron are reheated for rolling or rerolling. A *balling-furnace.*

Rein. 1. (*Saddlery.*) A strap or cord by which a horse is driven or controlled. The ends of the rein are fastened to the bit-rings, as, —

Driving-rein.	Check-rein.
Bearing-rein.	Gag-rein.
Safety-rein.	Overhead-rein.

The Scythians hung the scalps of their enemies to their bridle-reins. The Red Indians do the same. Attila is similarly represented.

The Japanese bridle-rein is often of silk.

2. (*Architecture.*) A *springer* or lower *voussoir* of an arch, which rests upon the *imposts.*

3. A rope of twisted and greased raw-hide.

Reins. The handles of a blacksmith's tongs, on which the ring or *coupler* slides.

Re-in-force'. An additional thickness imparted to any portion of an object in order to strengthen it, as, —

1. (*Ordnance.*) The enlarged portion of a cannon, extending from the *base ring* to the *chase.* It is formed in casting, or by shrinking on a band of metal.

The *first reinforce* is that nearest the breech, where the metal is thickest.

The *second reinforce* extends from the termination of the first to a point forward of the *trunnions.* These distinctions are obliterated in American guns of the later patterns.

The *Armstrong gun* (English) is built up of coils and reinforces around a steel tube.

2. A strengthening patch. (See PATCH.) It may be an additional thickness sewed around a cringle or eyelet-hole in a sail or tent-cover; a piece pasted around the buttonhole of a paper collar, etc.

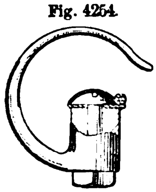
3. A patch on a tube, boiler, tank, etc.

Re-in-force'-ring. (*Ordnance.*) A flat molding at the breech end of the reinforce.

Rein-hold'er. (*Menage.*) A clip or clasp on the dashboard of a carriage, to hold the reins when the driver has alighted.

Rein-hook. (*Harness.*) A hook on a gig-saddle to hold the bearing-rein.

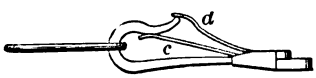
Fig. 4254.



Check-Rein Hook.

Rein-slide. (*Harness.*) A slipping loop on an extensible rein, which holds the two parts together near the buckle, which is adjustable on the standing part.

Fig. 4255.



Rein-Snap.

Rein-snap. (*Harness.*) A spring hook for holding the reins. In the example, one spring *c* retains the ring in the hook, and the other, *d*, forms a mousing to keep anything from accidental engagement with the point of the hook. See also SNAP-HOOK; HARNESS-SNAP.

Reis'ner-work. Inlaid work on the principle of the BUHL (which see). Reisner was a skillful practitioner of the art about the time of Louis XIV. He principally used woods of contrasted colors, while Buhl used metals and tortoise-shell by preference.

Imitations of this and buhl are now made by stamping instead of cutting out with the saw. At Birmingham, devices are stamped from sheet-brass and applied to papier-maché, the intervening depressions being filled up with successive coatings of black Japan varnish. See also BUHL; MARQUETRY; PARQUETRY; INLAYING, etc.

Re-joint'ing. (*Masonry.*) Pointing, as of walls.

Re-lay'. (*Telegraphy.*) A subsidiary electromagnetic circuit made and broken by the primary circuit. By means of the relay-magnet, a current too feeble to produce sensible mechanical effects at a distance is made to set in action an auxiliary current competent for the work. Invented by Professor Joseph Henry. — PRESCOTT, *History of the Electric Telegraph.*

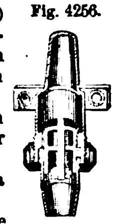
Re-lay'-mag'net. (*Telegraphy.*) A small electro-magnet requiring but a weak current to charge it, and having an armature to which is attached a lever ending in a platinum point, which impinges against a back stop whenever the armature is attracted by the electro-magnet. This back stop and armature form part of the circuit of a local battery to the sounder or register. If the main-line current arriving at an office is too weak to work the sounder or register, the relay is placed in the main circuit and operates to close a local circuit to the sounder or register whenever its armature lever is attracted against its back stop. This device, indispensable on long lines of telegraph, was invented by Professor Henry. See MORSE INSTRUMENT.

Re-lief'. 1. (*Sculpture.*) The prominence of a sculptured figure from the plane surface to which it is attached. According to the degree of prominence, it is known as *alto* or *high relief, mezzo* or *demi-relief,* and *basso* or *low relief.* See RILIEVO.

2. (*Fortification.*) The total hight of the parapet above the bottom of the ditch.

Re-lief'-valve. 1. (*Steam-engine.*) A valve belonging to the feeding apparatus of a marine-engine, through which the water escapes into the hot-well when it is shut off from the boiler.

Fig. 4256.



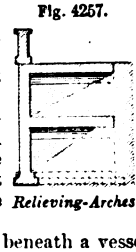
Relief-Valve for Beer-Engine Pipes.

2. A valve so arranged as to open outward when a dangerous pressure or shock occurs, to allow escape of water.

3. A valve to allow access of air to a barrel from which liquor is drawn.

Re-liev'ing-arch. An arch at the back of a revetment or retaining wall, to relieve the pressure of the bank upon the wall, and act as a tie or interior buttress. Arches of this description have their axes and the faces of their piers at right angles to the face of the bank. The front end is usually closed by a vertical wall. The arches of two stories are shown in section, with the retaining wall, and a talus of soil occupying a part of the space beneath each.

Fig. 4257.



Relieving-Arches.

Re-liev'ing-tack'le. (*Nautical.*) *a.* A tackle temporarily attached to the end of the tiller, to assist the helmsman in bad weather, and act as a guard in case of accident to the tiller ropes or wheel.

b. A tackle from a wharf passed beneath a vessel when careened, and secured to the opposite side, to

act as a guard against upsetting and to assist in righting.

Rel'ish. (*Joinery.*) The projection of the shoulder of a tenoned piece beyond the part which enters the mortise. See TENON.

Rem'bérge. (*Vessel.*) A long, narrow, low rowing vessel of war, formerly used by the English.

Rem'blai. (*Fortification.*) The elevated portion of earthworks formed by the disposition of the *déblai*, or excavated materials.

Re-lief'-line En-grav'ing. The process of Mr. Palmer of England, about 1840, in which a blackened copper plate is covered with a ground of a definite thickness of sulphate of lead, wax, and resin; a tracing or photographic image is transferred to the *ground;* the ground is cut away by gravers or etching-points, so as to make lines down to the metallic surface, which is blackened so as to enable the effect of the work to be seen. The plate then receives a coating of graphite, and an electro-cast is made, forming a raised surface from which to print.

The hight of the little ridges in the cameo cast in copper is equal to the depth of the ground through which the design was cut. In the broad spaces — the lights, where the lines are at a considerable distance apart and there is a danger of ink attaching itself to the plate in inking — wax is dropped upon the ground before *blackleading*, so as to make elevations at those points which become depressions in the electro-cast.

This process was adopted by Jewett and Chandler of Buffalo for many years in making the cuts for the Patent Office reports, and is still practiced by Mr. Chandler in making the cuts forming the illustrations of this Dictionary and numerous other works.

Re-lief'-pro'cess. See PHOTO-RELIEF PROCESS.

Rem'e-dy. (*Coining.*) The allowance at the mint for deviation from the exact standard fineness and weight of coin. In England the *remedy of the mint* is: Gold, 12 grains per pound in weight; $\frac{1}{16}$ of a carat in fineness. Silver, 1 dwt. per pound in weight; 1 dwt. per pound in fineness. Copper, $\frac{1}{40}$ of the weight, both in weight and fineness.

The remedy of United States gold coin is, double-eagle, one half grain; smaller gold coins, one quarter grain.

On coin in bulk, $\frac{1}{100}$ of an ounce in 5,000 gold pieces of the denominations $20, $10, $5, $2.50; $\frac{1}{100}$ of an ounce in 1,000 gold pieces of the values $3 and $1.

The remedy on United States silver coin is $1\frac{1}{2}$ grains to the piece. Or, on coin in bulk, $\frac{3}{100}$ of an ounce in 1,000 silver pieces of the values $1, 50 c., 25 c.; $\frac{1}{100}$ of an ounce on 1,000 dimes. On the minor coins, 3 grains for the 5-cent piece; 2 grains for the 3 and 1 cent pieces.

Re-mon'toir. (*Horology.*) A mechanism designed to render the force which sustains the movement of the escapement perfectly even.

Re-mon'toir-es-cape'ment. An escapement in which the scape-wheel is driven by a small weight raised by the clock at intervals of thirty seconds, usually; or by a spiral spring on the scape-wheel arbor, wound up a quarter or half turn at the said intervals.

Rem'o-ra. (*Surgical.*) An instrument to retain parts in place; as one to keep the intestines from protruding at the inguinal ring after the operation of castrating, or one to maintain a fracture in place or a luxation reduced.

Ren'der. 1. (*Nautical.*) To pass through the block; said of a rope. To *reeve.* To *rack* a tackle is to seize the parts together and prevent *rendering.*

2. To try out lard or tallow.

Ren'der-ing. 1. (*Plastering.*) The first coat of plaster on brick-work. It is followed by the *floating* coat and the *setting* coat, the latter of *fine* stuff.

The first coat is sometimes termed the *pricking-up* coat. When on lath it is said to be laid. *Rendered* and *set* is complete two-coat work on brick or stone.

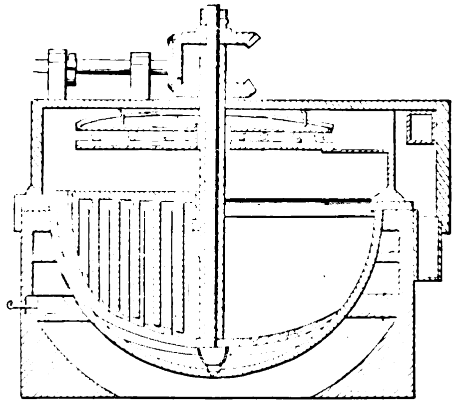
2. The process of trying out oil or lard from fat. See RENDERING-APPARATUS; LARD-TANK.

Ren'der-ing-ap'pa-ra'tus. An apparatus for extracting oil and lard from fatty animal matters. The object to be attained is to separate the purely oleaginous part from the cellular tissue inclosing it. In household economy this is effected by simply heating the fat, previously cut into small pieces, in an open vessel over the fire; this separates the greater part of the purely oily matter. The scraps, called *cracklings*, are freed from the remainder by straining and pressure.

Somewhat more complicated arrangements are introduced when the process is conducted on a large scale, in order to more perfectly extract the oily matter with economy of labor and material.

Black's apparatus consists of a pan set in a furnace, which has two flues, the lower one communicating with the fireplace by means of apertures,

Fig. 4258.

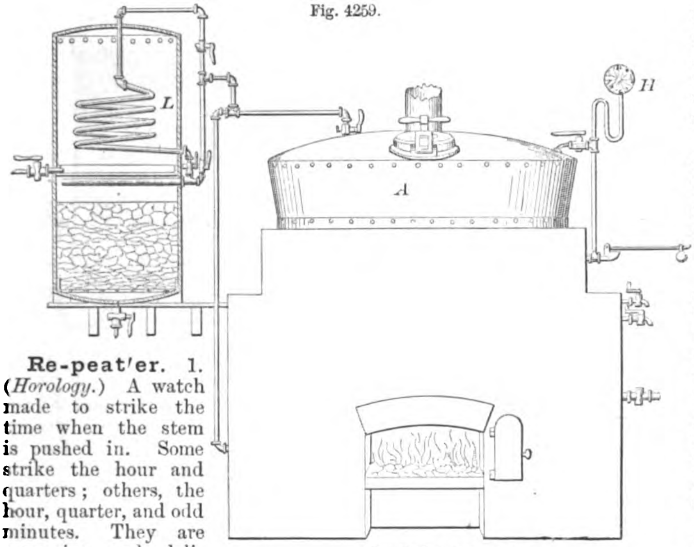


Rendering-Pan.

which may be closed when desired by dampers. The pan has a perforated false bottom, and in the space between the bottom and false bottom is arranged a rotary stirrer. Above the false bottom is a hollow rotary shaft provided with arms. The pan has a tight cover, to which are suspended two plates, the upper one being provided with gutters. The interior of the pan communicates with a condenser which is connected with a drain or sewer. The vapors are condensed by means of cold water supplied by perforated boxes.

Gray's apparatus (Fig. 4259) consists of a closed tank or kettle *A* having a jacket covering the part which comes in contact with the fire. The space contains water, which is heated so as to render the lard in the kettle. The vapors and gases which escape from the lard during the process of rendering are carried through a coil *L* in a condenser, and afterward through a gas-purifier, or they may be conducted into the furnace and burner. A gage *H* indicates the amount of steam-pressure; try-cocks at different hights are provided for drawing off the lard in a fluid state. See also LARD-BOILER; LARD-TANK.

Fig. 4259.



Rendering-Apparatus.

Re-peat'er. 1. (*Horology.*) A watch made to strike the time when the stem is pushed in. Some strike the hour and quarters; others, the hour, quarter, and odd minutes. They are expensive and delicate, owing to the assemblage of so many parts within so limited a space.

Some *repeaters*, in addition to their announcement of the hour when called on, will strike the hours and quarters as they recur. A *striking* watch merely has not the faculty for *repeating* when called on so to do.

Alarms are also attached to watches. The machinery is somewhat similar to that of the alarm-clock.

James II., in person, heard arguments on interfering applications for patents for repeating-watches (Barlow *vs.* Quare), and decided in favor of Quare (1676). Priority of invention belonged, however, to Barlow, who employed two pins to strike the hours and quarters, while Quare afterward effected this with one only.

The smallest repeating-watch ever known was made by Arnold for George III., to whom it was presented on his birthday, June 4, 1764. Although less than six tenths of an inch in diameter, it repeated the hours, quarters, and half-quarters, and contained the first ruby cylinder ever made. Its weight was that of an English silver sixpence. Arnold made it himself, and also the tools employed in its construction. The king presented Arnold with 500 guineas ($2,500) for this curious watch, and the Emperor of Russia afterward offered the maker 1,000 guineas for a duplicate of it, which Arnold declined.

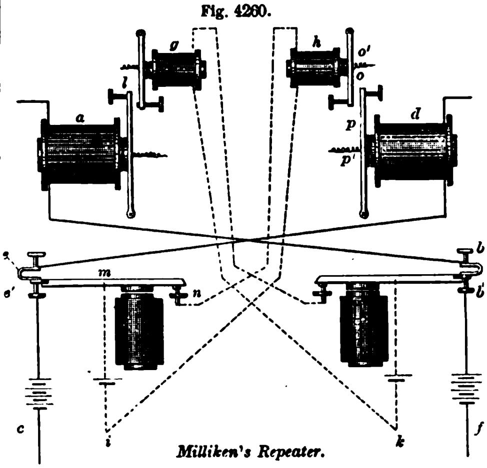
2. (*Fire-arms.*) An arm which may be caused to fire several successive shots without reloading. In Colt's and other revolvers, the charges are placed in chambers in a rotating cylinder, and brought successively in line with the barrel; while in the Spencer, Winchester, and Henry rifles, and others of that class, a number of the cartridges are inserted in a chamber at the butt or beneath the barrel, and fed and discharged singly by mechanism connected with the lock devices; metallic cartridges only are employed, the case being automatically ejected after each discharge. See FIRE-ARMS; REVOLVER.

3. (*Telegraphy.*) An instrument for automatically resending a telegraphic message at an intermediate point, when, by reason of length of circuit, defective insulation, etc., the original line current becomes too enfeebled to transmit intelligible signals through the whole circuit. The original circuit being divided into two or more shorter circuits, the sounder or armature lever of one circuit opens and closes another circuit by an action similar to that of a *relay*.

Fig. 4260 is a plan of Milliken's. The main-line wire from one direction (west, for example) passes through the relay-magnet *a* and the repeating points *b b'* of the opposite sounder, and thence to the battery and ground at *f*; the eastern line passes through *d*, *e e'*, and to *c*.

The extra local magnets *g h* are so arranged that when either of their armatures is released, it is drawn back by the spring attached to its lever, bringing the latter firmly in contact with the armature lever of the corresponding relay. The dotted lines show the circuits from the extra local batteries at *i k*. If the main circuit be broken in the western wire, the relay *a* breaks the local circuit in the sounder at *l*. The movement of the lever *m* of the sounder first breaks the extra local circuit at *n*, causing the magnet *h* to release the armature *o* which is drawn back by the spring *o'* against the top of the lever *p*, and the eastern main circuit is also broken at *e e'*. The lever *p* is prevented from falling back when the circuit of *d* is broken by the tension of the spring *o'*, which is so adjusted as to be greater than that of the spring *p'*. The apparatus on the right-hand side of the repeater therefore remains quiet while the west is working, and *vice versa;* the current through *d* being always restored before that through *h* is broken, which is effected by the U-shaped spring on the screw *e*.

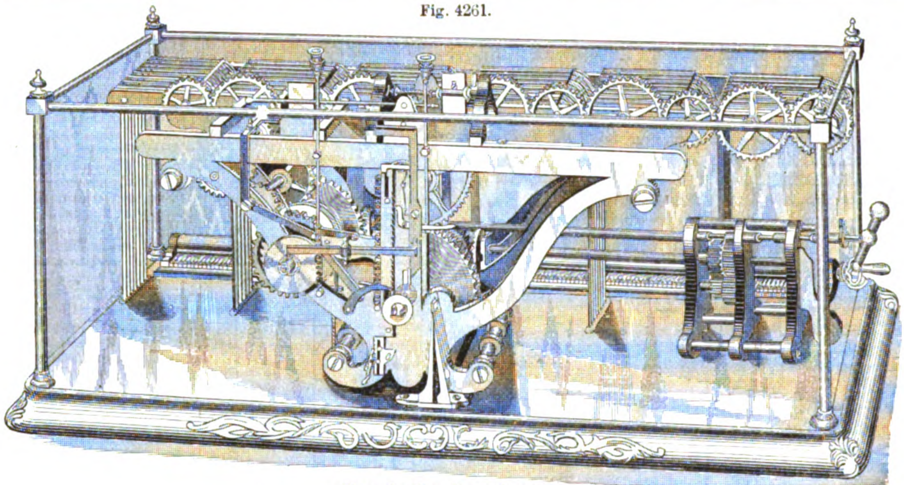
Fig. 4260.



Milliken's Repeater.

Fig. 4261 is a fire-alarm telegraph-repeater. It has a series of large broad-faced circuit-wheels having teeth, in sets of 8, arranged spirally on its periphery. These are faced with platinum, and as the wheels are revolved by clock-work and weight, make contact with springs also armed with platinum and arranged in sets of 8, throwing the current into the line wires to the different stations in order, or to such of them as the operator may desire. Those not wanted are thrown out of circuit by a switch-board. Numerical signals from 1 to 998 may be transmitted. In order that these may be repeated automatically, a series of toothed regulating-wheels, so arranged as to be readily attached or detached, is provided. Each of these has only the teeth corresponding to the particular signal which it represents, and when placed in the train the current is not transmitted through the current-wheels by the springs which make the circuit through it and the circuit-wheels, when the interspaces between the omitted teeth are out of contact with the springs. The times in which these and the circuit-wheels make a revolution are automatically adjusted, so that equal intervals shall elapse between the striking of each tap of the signal, which denotes the units, tens, or hundreds, as the case may be; the

Fig. 4261.



Chester's Fire-Alarm Repeater.

gearing then ensures a complete revolution of the circuit-wheel; the remaining part of the signal, if it consists of more than one place of figures, is struck in a similar way, and the operation is continuously repeated until the regulator-wheel is displaced.

Re-peat′ing-cir′cle. A reflecting-instrument, on the principle of the sextant, for measuring angular distances. The image of one of the observed objects, after being reflected from a mirror on a pivoted arm and again from a fixed mirror, is brought into coincidence with the other seen by direct vision; the *apparent* angular distance is thus doubled, and the graduations of the circle, which are continued all the way around its limb, thus embrace 720° of arc.

It was first invented by Mayer about 1744. Borda, after whom it is frequently called, in 1780, introduced a second arm and vernier, to which Troughton subsequently added a third.

The mean of the readings given by each arm is taken as the true angular measurement, which may be repeated continuously around the circle, bringing a different part of the limb into use at each repetition, thus tending to eliminate errors of centering and graduation.

Notwithstanding the accuracy theoretically obtainable by this principle, there appears to be, says Sir John Herschel, some constant source of error in this instrument which in a large degree counterbalances its theoretical advantages. It has consequently never come into extensive use either in this country or England. See REFLECTING-CIRCLE; SEXTANT; QUADRANT.

Re-peat′ing Fire-arm. One which discharges several successive shots without reloading.

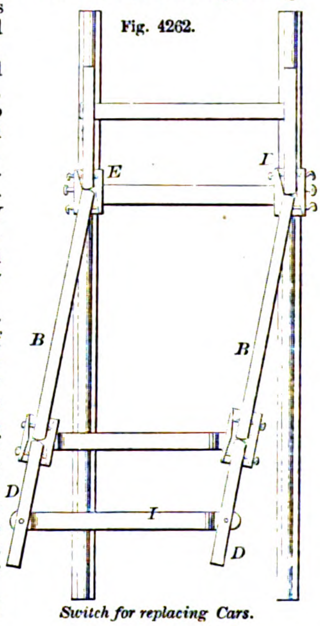
"After dinner was brought to Sir W. Compton a gun to discharge seven times, the best of all devices that ever I saw, and very serviceable, and not a bawble; for it is much approved of, and many thereof made." — PEPYS'S *Diary*, 1662.

In the armory of the Tower of London are several Indian pieces known to be as old as the fifteenth century, and in principle similar to our revolvers. They have the defect of liability to ignite all the charges at once, and were abandoned as dangerous and useless. Specimens of British and French manufacture are in the museums of England and France; and the fire-arms of Collier, an American gunsmith, 1818, and of another American in 1819, have the defects of their predecessors. Colonel Colt is believed to be the first inventor of a really available repeating pistol. (TEMPLE.) His first device was a number of barrels, but he subsequently devised the rotating cylinder breech and single barrel. See also MAGAZINE FIRE-ARM; REVOLVER.

Re-peat′ing-watch. (*Horology.*) One constructed to strike the hours and quarters when the stem is pushed in. See REPEATER.

Re-plac′ing-switch. A device forming a bridge by which the wheels of cars are replaced upon the track. A section is laid upon each track, and has a shoe *E* to which an inclined piece *B* is jointed. The inclined section rests upon another shoe. *D I* are farther extension-pieces which are pushed in below the wheels.

Fig. 4262.



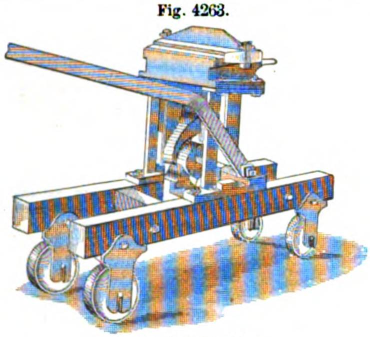
Switch for replacing Cars.

Re-pous-sé′-work. A kind of chasing. It is effected entirely by the hammer. The workman uses a plain flat sheet of silver, having before him a model of the article to be produced. The plate rests upon a soft bed of pitch or other composition, and with a small hammer the workman produces indentations on the inner surface of the plate, corresponding to the design. A small steel punch is, in some cases, employed; and if the relief is accidentally made too high, it is reduced by counter hammering.

Benvenuto Cellini, 1500 – 70, is celebrated in this and kindred branches of the arts.

Re-press′ing-ma-chine′. A machine for repressing brick after being partially dried. Also used for making brick direct from the clay, in warm climates, where brick are used without burning;

Fig. 4263.

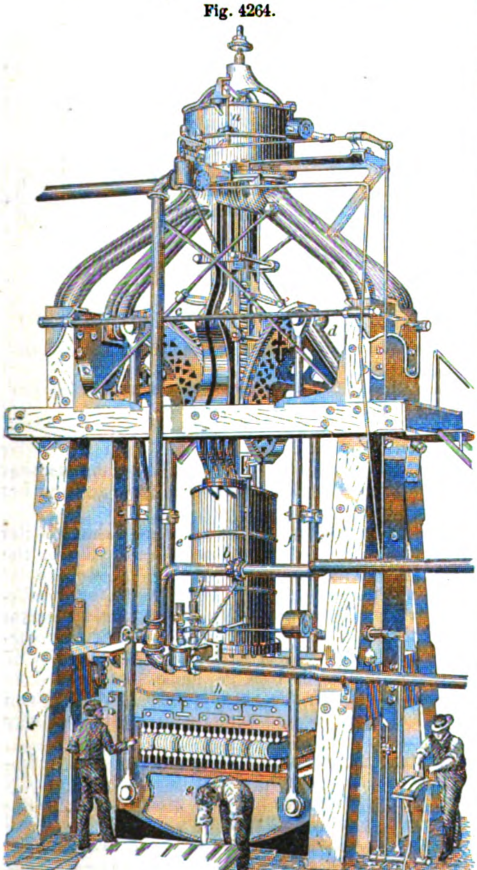


Repressing-Machine.

adobes. In that illustrated, the brick is placed within the mold, the sliding cover which had been pushed aside for that purpose being replaced, the lever is depressed, raising a platen forming the bottom of the mold; on throwing up the lever the reverse movement of the eccentric allows the platen to descend a certain distance, the sliding cover is slipped aside, and a farther upward movement of the lever causes the platen to rise sufficiently to permit the brick to be removed.

Re-press'ing-press. A press designed for compacting bales of cotton, etc., into the smallest possible compass for transportation. Grader's (Fig. 4264) has two steam-cylinders *a b*, the upper one of which is of greater diameter than the lower. The piston of the lower has a ratchet which engages with the toothed arcs *c d*, to whose upper extremities are attached rods *e e' f f'* connected with the platen *g*. Steam admitted below the lower piston causes an upward movement of the segments, which, through the medium of the rods *e e' f f'*, raise the platen and compress the bales placed between it and the immovable bed *h*. If a greater pressure is desired than is thus obtainable, the piston of the large cylinder *a* is caused to descend; a clutch on its piston-rod then engages the teeth on the ratcheted piston-rod of the lower cylinder, and on admitting steam below the upper piston a farther upward movement is imparted to the platen *g* through the medium of the ratchet, arcs, and connecting-rods.

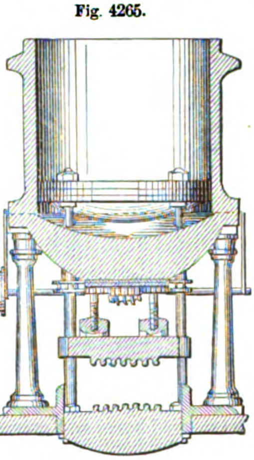
Fig. 4264.



Grader's Repressing-Press.

The power of the press may be varied, — by using the lower cylinder alone; by working the upper cylinder expansively; by working the upper cylinder expansively and the lower under full boiler pressure; and by using full boiler pressure in both cylinders.

Fig. 4265.

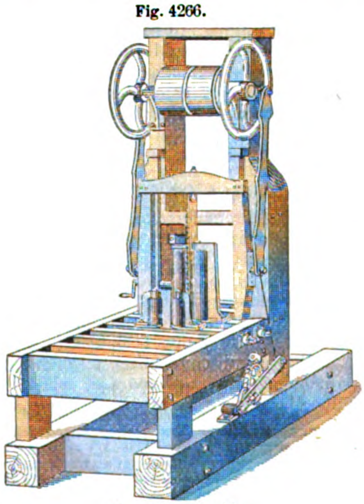


Repressing-Press.

The repressing-press may be of any suitable form and construction, but the steam or hydraulic form shown in Fig. 4265 is compact and effective.

Rere'dos. 1. (*Architecture.*) The wall at the back of an altar or seat. In Gothic churches it is usually in the form of a screen detached from the eastern wall, and is ornamented with niches, statues, etc., paintings, or tapestry. Fine examples occur at Durham and St. Albans, England.

Fig. 4266.



Resawing Machine.

2. A projecting buttress on the back of a fire-place, or a movable plate occupying a similar position. It is called a *fire-back*, and its office is to throw forward the fire, so that it may radiate into the room. Hollinshed calls it a *rere-dorse*.

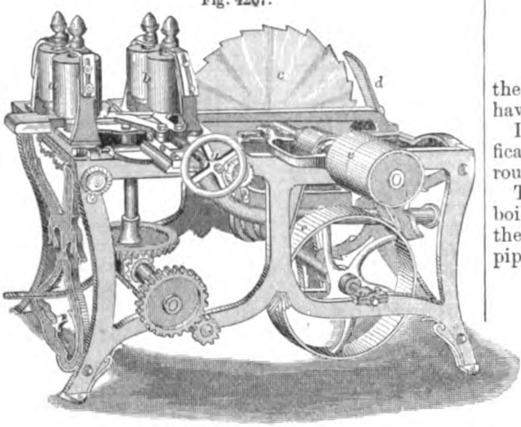
Re-saw'ing-ma-chine'. (*Wood-working.*) A machine for cutting up squared timber into small stuff or boards.

In the machine, Fig. 4266, a reciprocating-saw is employed. The longitudinal feed is effected by the usual vertical rollers, rotated by gear connection with a shaft caused to revolve by a pawl at the end of a lever connected with the journal of the pitman, which causes the reciprocation of the saw-frame.

A hand-crank and screw control the transverse feed of the stuff.

In Fig. 4267, the squared piece to be cut up is drawn between the adjustable feed-rollers *a b*, by which it is presented to the saw *c*; the sword *d* guides

Fig. 4267.



Resawing-Machine.

the severed board and prevents its fouling the operative mechanism. The roller-turning and saw-rotating gears are driven by the band pulleys *e e*, and the transverse movement of the carriage *f* may be effected by turning the hand-wheel *g*.

Re-serve'-style. (*Cotton-manufacture.*) A method of calico-printing in which the white cloth is impressed with figures in resist paste, and is afterward subjected first to a cold dye, as the indigo vat, and then to a hot dye-bath; the effect being the production of white or colored spots upon a blue ground. Also known as the *resist-style*.

Res'er-voir. 1. A pond for containing a supply of water for canal supply, irrigation, or the use of dwellers in cities.

A reservoir erected by Nebuchadnezzar at Sippara was 140 miles in circumference.

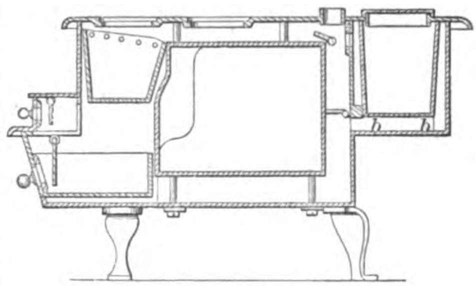
The lake of Mœris, constructed by the Pharaoh of that name to receive the superabundant waters of the Nile at the time of overflow, and afterward yield them for prolonged irrigation, was described by Diodorus Siculus (60 B. C.) as existing till his day. The circuit he gives, 3,600 furlongs, is almost incredible. The canal connecting it with the river was 80 furlongs long and 300 feet wide. Sluices commanded the water-way by opening and shutting.

The reservoir on Mill River, Mass., which burst with immense damage to life and property, May 16, 1874, was an artificial lake between high hills. The confining dam at the lower end was a stone-wall five and a half feet thick at bottom, three feet at the top, and 25 feet high. This wall was about 300 feet long, built of uncut stone from a foundation four feet below the level of the ground at the lower side, and was backed on the upper side with a bank of earth interwoven with branches of trees. The dam had been built eight years at the time of the catastrophe. See DAM.

2. An attachment to a stove or range to hold hot water.

It is heated by proximity to the stove itself or to

Fig. 4268.



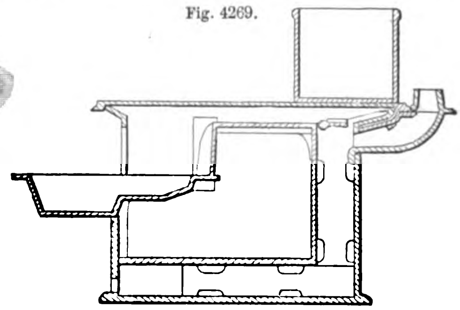
Reservoir-Stove.

the stovepipe. In Fig. 4268, it is behind the stove, having a flue *b b* around and beneath it.

In Fig. 4269, it is on top of the stove. In a modification of the latter form the boiler is made to surround the stovepipe.

The reservoirs of ranges are usually vertical iron boilers, connected by pipes with the water supply of the city. The water from the main passes through pipes in the fire-chamber, or through a water-back,

Fig. 4269.



Stove with Reservoir.

and thence to the boiler. A pipe from the boiler proceeds to the sink to supply hot water at that point, a branch leading to the bath-room and another to the laundry.

Res'er-voir-stove. One having a large boiler attached, to be constantly heated by the fire in the stove. See RESERVOIR.

Re-sid'u-a-ry-gum. Also known as *candle-pitch* or *chandler's gum*. The dark residuary matter from the treatment of oils and fats in the manufacture of stearine. It is darkened by the action of acid, and thence derives its name. It is used in coating fabrics for the manufacture of roofing, and combined with tar and asphate in making mastics and cement.

Res'in. A vegetable product composed of hydrogen, carbon, and oxygen. Distinguishable generally from gum by its solubility in alcohol and insolubility in water, while gums are soluble in water and insoluble in alcohol. There are many varieties of resins, derived from different species of trees. Some are naturally combined with the gums, forming what are known as gum-resins. Both these and the pure

resins are generally termed gums. Resins become negatively electrified by friction. They are largely employed in making varnishes, and some are used as medicines. The most common variety, known as *rosin*, is derived from the distillation of crude turpentine.

Dr Sacc, of Nuenburg, Switz., gives the following summary as to the resins of commerce: —

Copal, amber, dammar, common rosin, shellac, elemi, sandarach, mastic, and Caramba wax can be reduced to powder.

The following will become pasty before melting: amber, shellac, elemi, sandarach, and mastic; the others will become liquid at once.

In boiling water, Caramba wax will melt; common rosin will form a semifluid mass; dammar, shellac, elemi, and mastic will become sticky; while copal, amber, and sandarach will remain unchanged.

Dammar and amber do not dissolve in alcohol: copal becomes pasty; elemi and Caramba wax dissolve with difficulty; while rosin, shellac, sandarach, and mastic dissolve easily.

Acetic acid makes common rosin swell; on all the others it has no effect.

Caustic soda dissolves shellac readily, rosin partly; but has no influence on the others.

Amber and shellac do not dissolve in sulphide of carbon; copal becomes soft and expands; elemi, sandarach, mastic, and Caramba wax dissolve slowly; while rosin and dammar dissolve easily.

Oil of turpentine dissolves neither amber nor shellac, but swells copal; dissolves dammar, rosin, elemi, sandarach, and Caramba wax easily, and mastic very easily.

Boiling linseed oil has no effect on amber and Caramba wax; copal, shellac, elemi, and sandarach dissolve in it slowly, while dammar, rosin, and mastic dissolve easily.

Benzine does not dissolve copal, amber, and shellac, but does elemi and sandarach to a limited extent, and Caramba wax more easily; while dammar, rosin, and mastic offer no difficulty.

Petroleum ether has no effect on copal, amber, and shellac; it is a poor solvent for rosin, elemi, sandarach, and Caramba wax, and a good one for dammar and mastic.

Concentrated sulphuric acid is indifferent to Caramba wax; it dissolves all resins, imparting to them a dark brown color, excepting dammar, which takes a brilliant red tint.

Nitric acid imparts to Caramba wax a straw color; to elemi, a dirty yellow; to mastic and sandarach, a light brown: it does not affect the others.

Ammonia is indifferent to amber, dammar, shellac, elemi, and Caramba wax; copal, sandarach, and mastic become soft, and finally dissolve; while rosin will dissolve at once.

It is not difficult by means of these reactions to test the different resins for their purity.

Gum-resins.

Common Name.	Botanical Name.	Native Place.	Quality, Use, etc.
Amber	....	Prussia, Poland, etc	Found in the mines, rivers, and sea-coasts of Prussia. Used in varnish and for mouth-pieces of pipes.
Ammoniacum	Dorema ammoniacum	Persia, etc	Used as a stimulant in medicine.
Anime or Animi	Hymenæa courbaril Vateria indica	Brazil India	Used for varnish. The Indian kind known in commerce as "Indian Copal."
Asphalte	....	Trinidad, Dead Sea, etc.	Forms a basis of black varnishes, as Japan black, etc. Used with sand for paving material. Affords petroleum or rock oil.
Assafœtida	Narthex assafœtida, etc.	Central Asia	Used as a stimulant and antispasmodic in medicine.
Australian gum-resins	Eucalyptus (various)	Australia Tasmania	Affords resins for varnishes, and produces tannin.
Balata	Achras dissecta	Guiana	One of the Sapoteæ; allied in qualities to gutta-percha.
Benzoin or Benjamin	Styrax benzoin	E. Indian Islands	Fragrant. Used in incense, perfumery, pastilles; affords benzoic acid.
Canada balsam	Abies balsamea, etc	Canada	Becomes solid on exposure to the air. Used to mount microscopic objects, for varnish, and as a cement for optical glasses.
Caoutchouc	Siphonia brasiliensi Ficus elastica, etc Urceola elastica	Brazil East Indies E. Indian Islands	The solidified milky juice of many families of plants. Is very elastic; has the property of uniting with sulphur, magnesia, etc.; is used for submarine coating, etc.; is of the highest value in mechanics and manufactures.
Copal	Hymenæa (various)	W. Africa, E. Indies, S. America	Used for varnish.
Dammar	Dammara australis	New Zealand	Used in making varnish. Obtained from Cowdi pine. Found where the tree has formerly grown.
Dragon's blood	Calamus draco Dracæna draco, etc	East Indies Canaries S. America	Deep reddish-brown color. Used (after being dissolved in alcohol) for staining material for marble, wood, leather, etc., and to color varnishes.
Elemi	....	Tropics	Ointment, plasters, varnish.
Galbanum	Ferula galbaniflua	Levant	Used in pharmacy.
Gamboge	Cambogia gutta Hebradendron Gambogioides, etc	Cambogia, Siam, etc	Yellow. Used as a pigment and as a gold lacquer, etc.
Geranium	Monsonia burmanni	S. Africa	Produces much resin. Found in the sands about the Cape of Good Hope. The resin is produced after the death of the plant.
Gum-dragon	(See Dragon's blood.)		
Gutta-percha	Isonandra gutta	Malay Islands	The solidified milky juice of many species of Sapotaceæ. Being plastic when heated, is used in molding, electro-plating, etc. Is a bad conductor of both heat and electricity.
Indian copal	Vateria indica	India	Called "Piney Varnish." Similar to Animi.
India-rubber	(See Caoutchouc.)		
Kino	Pterocarpus erinaceus	Gambia	Used as an astringent in medicine.
Lac	Ficus religiosa Butea frondosa	India	Resin produced by the puncture of a hemipterous insect on the tree, especially the "Peepul." Sold in commerce as shellac, threadlac, blocklac. Used to make sealing-wax, glass-cement, varnishes, and for bodies of hats, etc.
Mastic	Pistacia lentiscus	Scio	Used for varnish. Employed by dentists. Aromatic, astringent.
Myrrh	Balsamodendron myrrh	Shores of Red Sea	Used as an antispasmodic, stomachic, etc., and in tooth-powder.
Piney varnish	(See Animi and Indian copal.)		
Pitch	Pinus sylvestris	Sweden, etc	The residuum of the distillation of pyroligneous acid from wood-tar.
Rosin	Pinus palustris, etc	N. America, etc	The residue left after the distillation of oil of turpentine from the raw turpentine.
Sandarach	Callitris quadrivalvis	Algiers	Used in varnishes. When powdered, affords pounce.
Scammony	Convolvulus scammonia	Asia Minor	Used as a purgative in medicine.
Shellac	(See Lac.)		
Storax	Styrax officinale	Asia Minor	Soft; unctuous, and used as an expectorant. Incense.

Common Name.	Botanical Name.	Native Place.	Quality, Use, etc.
Storax (liquid).....	Liquidumber	United States	Fragrant; bitter; expectorant.
Tar (wood)........	Pinus sylvestris	North Carolina, Sweden, and Russia	Obtained by slow distillation of the branches and roots of the pine, etc., whilst burning in a nearly closed pit.
Turpentine	Pinus palustris........	America...........	Used in medicine, painting, and as a solvent for resins.
Turpentine (Strasburg)..........	Abies picea............	Europe............	
Turpentine (Venice)	Larix europoea.........	Europe............	
	Gums Proper.		
Gum-arabic........	Acaia arabica et vera...	N. Africa, Asia, etc.	Finest of the gums. Soluble in water.
Gum (British)......	Solanum tuberosum ...	Britain, etc.......	Torrefied potato-starch. Called dextrine.
Gum-tragacanth..	Astragalus tragacantha, etc............	Asia Minor, Persia	For mucilage and as a substitute for gum-arabic.
Gum (various).....	Pyrus, prunus, etc.....	Britain, etc......	Soluble in water. Exudes from apple, pear, cherry, and other trees.

Re-sist′. (*Dyeing.*) A material applied to cotton cloth to prevent the action of a mordant or color on those portions to which it is applied in the form of a pattern.

Resists act mechanically or chemically.

Fat or paste forms a mechanical resist, as it prevents the access of the mordant or color.

Chemical resists act upon the color, and prevent its fixing itself in the fabric.

2. (*Calico-dyeing.*) A process in which those portions of the cloth which are intended to remain uncolored are saturated with a substance which resists the action of the dye when immersed in the dye-vat.

The *resist*, a preparation of copper, imparts a brown tint to those parts to which it is applied, and the cloth is dipped in the dyeing solution, indigo in lime-water, with a proportion of copperas, which deoxidizes and decolorates the indigo; on being removed from the vat the cloth is of a greenish hue, which soon becomes blue by the reoxidation of the indigo on its contact with the air; the parts covered by the resist become charged with blue in the vat, the copper salt parting with its oxygen to the indigo. The blue thus formed has no union with the fiber, and is easily removed by weak acid, while that formed in the spots not touched by the resist remains fast.

In the *china blue* process the figures are printed with indigo thickened with paste, and by alternate immersion in lime-water and solution of copperas the indigo is dissolved and fixed in the spots where so applied by similar chemical reactions.

In the *discharge* process, employed for black and white, or red or chocolate and white, the cloth is passed through red or iron liquor, dried, and dipped in a mordant, — this is termed *padding;* it is then printed with citric acid, thickened with wasted starch, which discharges the mordant, so that when dyed the discharged figures are left white. Logwood is used for black, and madder for red and chocolate.

Re-sist′ance-box. (*Telegraphy.*) An inclosing-box for a resistance-coil.

Re-sist′ance-coil. (*Telegraphy.*) A coil introduced into a circuit to increase the resistance. It has normally a greater resistance than the remainder of the circuit. It is usually of a material of a less conducting power than the main circuit, say of German silver in a circuit of copper. See RHEOSTAT.

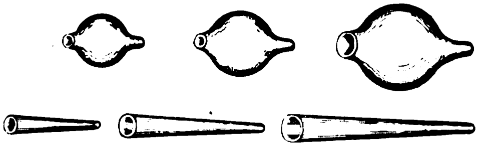
Res′o-na′tor. An instrument invented by Professor Helmholtz for facilitating the analysis of compound sounds. It consists, in its simplest form, of a tapering tube or a hollow bulb, spherical or nearly so in form, having an opening at one side for the air and a tube adapted to the ear at the other. When the instrument is fitted to one ear, the other being stopped, tones above or below the pitch of the resonator will be but imperfectly heard; but if a note be sounded corresponding to the peculiar or proper note of the resonator, it will appear greatly intensified.

Each resonator of this kind is adapted to the detection of but a single tone; but Helmholtz has also devised a compound resonator, consisting of three tubes sliding one within the other, so as to adapt it to notes of different pitch. Another form has been constructed, having holes like a flute, which are opened and closed by the fingers.

If the particular tone to which the resonator employed is attuned is contained in the sound under investigation, that tone will be sounded by the resonator.

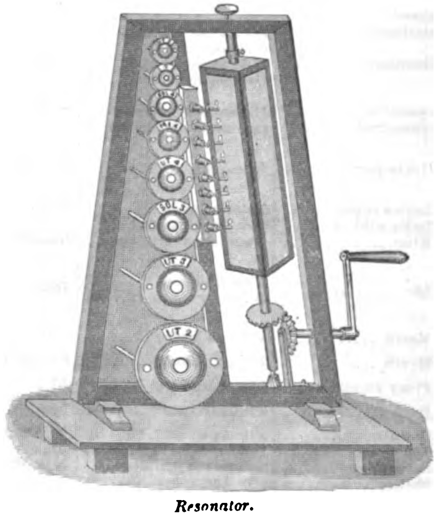
By employing a set of these any sound or sounds may be wholly or partially resolved into elementary notes, proving that those emitted by the voice or by musical instruments are not simple, but compound tones of different intensity and pitch, blending so as to form an apparently simple note when heard by the unassisted ear.

Fig. 4270.



Resonators.

Fig. 4271.



Resonator.

Fig. 4271 is an instrument for illustrating the influence of different musical tones upon the vibrations of flames. A series of organ-pipes tuned to produce the various notes of the gamut are arranged one above the other upon a vertical stand; at the side of this stand are a series of gas-jets. When air is forced into the pipes each flame will vibrate in concord with the pipe to which it is opposite.

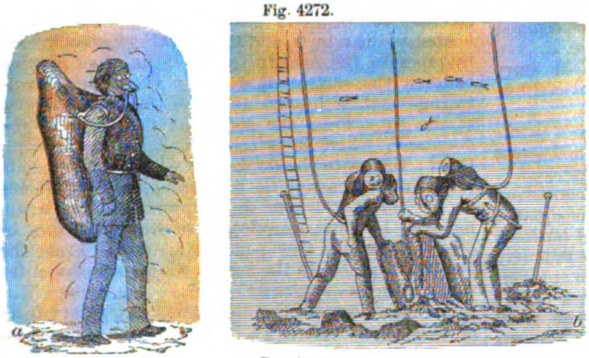
A four-sided mirror, on a vertical axis, is rapidly rotated by means of a crank and bevel-gears, when the reflections of the flames in the mirror present the appearance of a series of teeth as the flames rise and fall.

Res′pi-ra′tor. A device worn over the mouth to exclude injurious matters, such as smoke or dust, from the lungs; or to change the condition of the air by passing it through medicaments or gauze.

Respirators are used by cutlers and other grinders to exclude the dust from the lungs. Such respirators may have magnetic gauze, to attract the passing particles of steel. Respirators for persons having weak lungs have several plies of fine gauze, which warm the air as it passes through. Professor Tyndall's fireman's respirator is attached to a mask, and consists of an iron cylinder packed with cotton wool, glycerine, and charcoal. The wearer is enabled to remain from a quarter to half an hour in an atmosphere of smoke, which he could not otherwise breathe.

Galibert's respirator (*a*) is designed for the use of firemen and others who may be compelled to enter places filled with smoke or noxious gases. It consists of a fire-proofed canvas sack, inflated with air

Fig. 4272.



Respirators.

by a bellows and strapped to the back; this is provided with two pipes leading to a horn mouthpiece, through which the wearer breathes; a nose piece for expiration and goggles to protect the eyes complete the apparatus.

The apparatus of Rouquayrol and Denayrouze (*b*) is used by divers in submarine operations. It embraces an iron or steel reservoir, capable of resisting great pressure, and surmounted by a valved chamber which regulates the amount and pressure of the air inhaled by the workman. From this chamber a valved pipe having a mouthpiece, to be held between the lips, is conducted through the helmet which forms part of the armor worn by the diver. The cylinder is charged with compressed air by an air-pump at the surface, which need not be kept in continuous operation. The valves admitting air from the cylinder to the chamber, and from the latter to the lungs, open and close automatically during the process of breathing.

The cut illustrates a party of divers recovering a chest of gold which had been lost overboard from a steamer in the harbor of Marseilles.

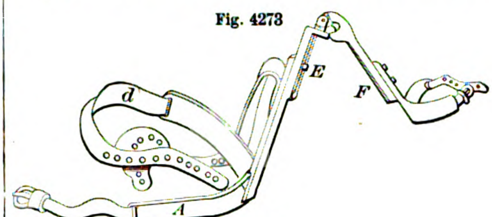
Rest. 1. (*Lathe.*) A device for supporting a piece of work in a lathe or vise.

A lathe-rest is a horizontal bar attached to the bed or shears, for the support of the turning-tool.

A slide-rest supports the turning-tool, and has motion in several directions by means of screws. See LATHE; SLIDE-REST.

2. A support for the muzzle of a gun in aiming and firing. The arbalest or cross-bow and the earlier hand fire-arms were always thus supported, and the long guns of the Moors and Arabs are still univer-

Fig. 4273



Rifle-Rest

sally provided with a device of this kind. In civilized countries the rest is employed by sharp-shooters and in practice-firing. See RIFLE.

It may consist of a stake or picket, whose pointed end is driven into the ground, the gun resting in a crotch at the upper extremity; or, as in some of the European armies, of a device having a screw point, by which it may be attached to a tree or other support.

In experimental firing, an adjustable table or trestle, on which all that part of the gun in front of the trigger-guard rests, is sometimes employed.

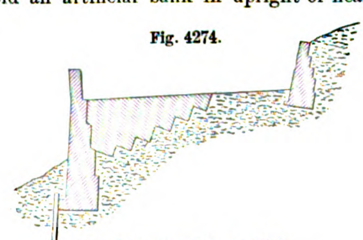
Fig. 4273 is Kinman's rest. It is strapped around the body of the rifleman by the belts *A d*. It has a rigid vertical arm *E* carrying the adjustable pivoted arm *F*. This has a free movement corresponding with the natural movement of the arm, and may be made to bear rigidly on the arm *E*, so as to afford a firm support to the piece in aiming and firing.

Res′tau-rant-car. One adapted for affording meals to passengers on board while traveling. See HOTEL-CAR.

Re-tain′ing-wall. (*Engineering.*) A wall erected to maintain a bank of earth in position, as in sunk fences, faces of earthworks, railway cuttings, sea-walls, etc.

A *retaining-wall* is, strictly speaking, one erected to hold an artificial bank in upright or nearly up-

Fig. 4274.



Retaining and Breast Walls.

right position. A *breast-wall* is one erected against a natural bank, or one whose materials are undisturbed, but whose face has been made by excavation.

The proportions of retaining-walls vary with the character and dip of the material at the back, and also with the degree of humidity of the strata cut by the excavation. They are re-

quired to stand against the lateral thrust and perpendicular weight.

The thickness under average circumstances may be, at the bottom, one third of the hight, diminished by set-offs on the inside. For walls exposed to the wash of water on the outside, and to the percolation of water, a greater thickness is required, say one half the hight.

The maetrial will vary with local and economic considerations, stone, brick, or concrete; of the latter the French form (see BÉTON) may be considered the most perfect.

Re-tic'u-lat'ed Glass. (*Glass.*) A species of ornamental glassware formerly made in Venice and recently revived by Pohl. It is produced by a network of air-bubbles inclosed in the glass and arranged in regular interlacing series. A bundle of small glass rods are arranged cylindrically, fixed by melted glass, and heated till the rods cohere. The bunch is then drawn out to a long cone and spirally twisted. Another bunch is similarly elongated and twisted in the other direction. One of these cones is inserted in the other and the two fused together. Wherever the little rods cross each other a bubble of air is inclosed, and the reticulated appearance is thus given.

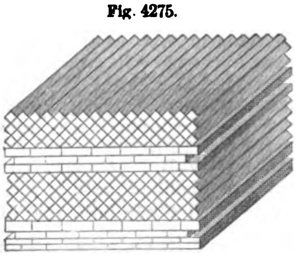
Re-tic'u-lat'ed Mi-crom'e-ter. Invented by Malvasia, about 1660, who constructed a network of silver wires, crossing each other at right angles, and dividing the field of the telescope into a number of equal squares. It is used for measuring small celestial distances. The reticulated micrometer consists of an eye-piece of low power, having stretched across it a number of wires at right angles to and at equal and known distances from each other. The wires are illuminated with the lantern, and the object measured by noting the number of divisions covered by it. See WIRE MICROMETER.

Re-tic'u-lat'ed Work. (*Masonry.*) Masonry formed of small square stones or bricks placed lozenge-wise. See RETICULATUM.

Re-tic'u-la'tion. A method of copying a painting or drawing by the help of threads stretched across a frame so as to form squares.

Re-tic'u-la'tum. A form of masonry consisting of layers of squared stone laid horizontally and obliquely so as to present their edges at the face of the wall, giving an appearance of *network;* hence the name.

Fig. 4275.



Opus Reticulatum.

Layers laid as described usually alternate with courses laid flatwise.

It is a fanciful style of masonry, adopted in ancient Rome, involving great labor, and is not now in use.

Re-tired' Flank. (*Fortification.*) A flank bent inward toward the rear of the work. For instance, the addition of such flanks, partially closing the *gorge*, changes a *redan* to a *lunette*. See LUNETTE.

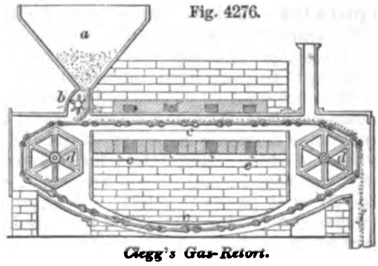
Re-tort'. A vessel in whose chamber an object is subjected to distillation or decomposition by heat, a neck conducting off the volatile products.

1. The retort of the pharmacy or laboratory is a vessel of glass, platinum, porcelain, or other material, and its various uses may be understood by consulting Muspratt, Morfitt, and Ure.

2. The retort of the gas-works is a cylinder or segment of a cylinder, and is formed of clay or of iron. The results are carbureted hydrogen, which passes off with various impurities which are eliminated by water, lime, copperas, etc.; and coke, which forms a valuable fuel. See GAS.

Clegg's *revolving-web retort*, for making coal-gas (Fig. 4276), has a hopper *a* from which the coal, in small fragments, is delivered by a feed-wheel *b* on to an endless web *c* made of plate iron, passing around two drums *d d*, whose revolution causes it to travel at a slow, fixed rate, so that the coal may be exposed a sufficient length of time to the heat of the flues *e e* from a lateral furnace by which the retort is heated.

Fig. 4276.



Clegg's Gas-Retort.

On reaching the pipe *f*, which is made air-tight by a suitable door or by dipping into water, the coke is discharged from the web.

Retorts for gas are now frequently made of clay, instead of iron, and are sometimes nearly 20 feet long, being charged from and discharging at each end. See GAS-RETORT.

Fig. 4277 shows the relation of the different parts forming the ordinary gas apparatus. The coal is heated in the retorts, and the resulting gas conducted by pipes to the *hydraulic main*, the pipes dipping beneath the surface of water in the main, constituting what is known as a *seal*, to prevent reflow of the gas. From the *main* the gas passes to the *condenser*, where it is cooled and the tar precipitated; thence to the *washer*, in which the ammonia is removed by passing the gas through water; thence to the *purifier*, where the sulphur compounds are removed by lime, sesquioxide of iron, iron ore, or other material. (See pages 953, 954.) From the *purifier* it passes to the *holder*, where it is stored for use. (See GAS, pages 943 - 957.)

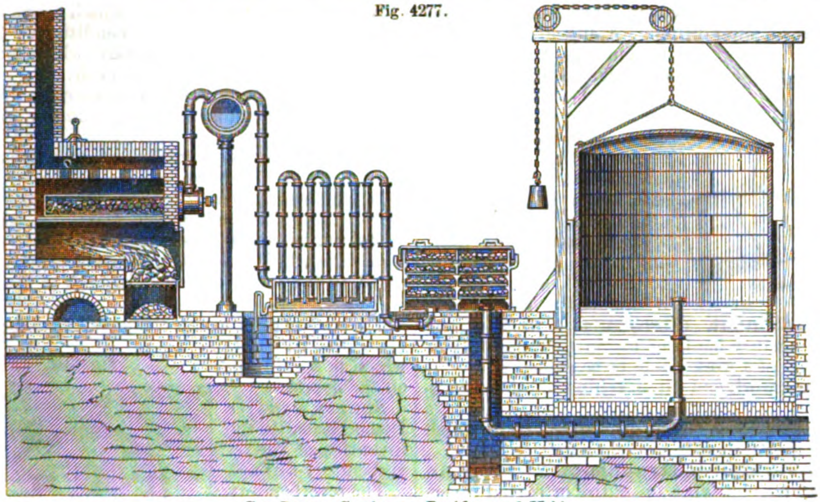
3. The retorts for the distillation of mercury from cinnabar, as erected by Dr. Ure at Landsberg, in Bavaria, resemble gas-retorts.

In the quicksilver works of New Almaden, in California, the ore is roasted in closed chambers with luted covers. At Idria, in Austria, the mode is a true furnace process, the ore being above the fire, the volatile results, both of combustion and sublimation, being conducted to condensing-chambers. In the Palatinate, retorts of pottery are used, their necks being luted into receivers containing water. See MERCURY-FURNACE.

4. The retort for silver amalgam is shown at *a* (Fig. 4278). It is commonly made twelve inches diameter inside, with a hood at the mouth having lugs to catch the clamp which fastens the door. The whole retort is set on cast-iron bearers in an arch, with the fire-grate under it. The neck of the retort passes through the back wall and connects with the condenser. The condensed quicksilver filters through a bag fastened on the end of the pipe, and is received into a tray. A cast-iron front, with closed doors, prevents the fumes from passing into the retort-room, and compels them to pass into the flue. Two tiers of amalgam trays may be used in this retort at the same time, one above the other. The bottoms of the lower tier are circular, so as to conform to the shape of the retort.

The iron retort for gold amalgam is a cast-iron crucible-like cup *b*, to which a flat iron top is fastened, a bent pipe of the size of small gas tubing passing out at the center, forming the neck of the

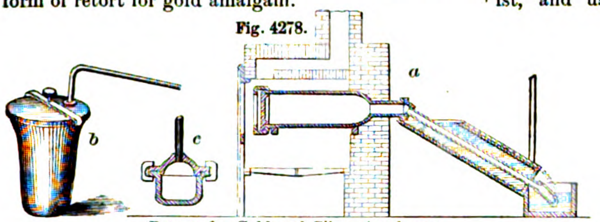
Fig. 4277.



Gas Retort, Condenser, Purifier, and Holder.

retort. Upon the application of heat the mercury is expelled and collected under water at the end of the tube, for future use. *c* is a section of another form of retort for gold amalgam.

Fig. 4278.



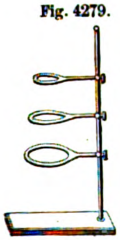
Retorts for Gold and Silver Amalgams.

5. Nitric-acid retorts are cast-iron cylinders, and resemble those for coal-gas, or are made of glass or pottery in a sand pot heated by the furnace fire.

There are many other retorts used in distillation and sublimation, such as those in which carbureted hydrogen and pyroligneous acid are obtained from wood, gas from tar, oil and other materials yielding hydrocarbons. See works on practical chemistry and chemical manipulations.

Re-tort′-scal′er. An instrument to cleanse the incrustation from the inside of coal-gas retorts.

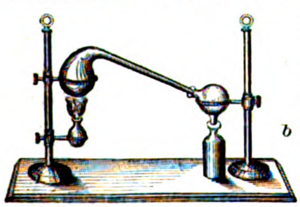
Fig. 4279.



a

It acts mechanically to break away the scale, or is an arrangement for driving air into the red-hot retort to burn away the incrusted matter.

Re-tort′-stand. (*Chemical.*) A device (*a*) for holding retorts or flasks while heat is applied by a spirit-lamp. It consists of a flat plate carrying an upright rod to which sliding rings of various sizes are fitted; these may be held at any suitable hight by clamp screws. A similar upright with sliding rings is frequently added for holding the receiver, as at *b*.

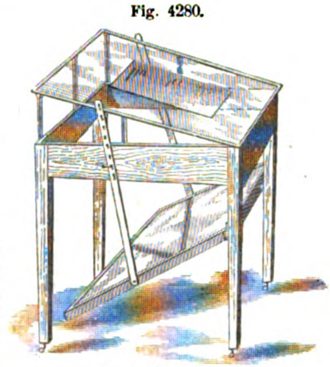


b

Retort-Stands.

Re-touch′ing-ta′ble. (*Photography.*) A glass-top table, or one with an opening to suit the size of a negative, inclined for the convenience of the artist, and used with a mirror below to throw light through a negative for the purpose of retouching. Formerly, india-ink and a hair pencil were used to improve and repair the surface, but a lead-pencil used as a stipple is now the usual instrument.

Fig. 4280.



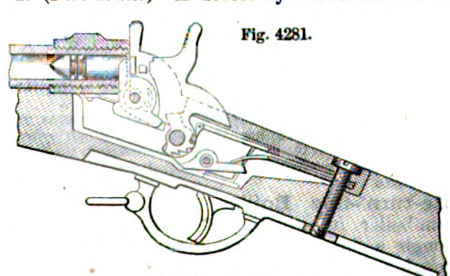
Retouching-Table.

Re-tract′or. 1. (*Surgery.*) *a.* A towel or rubber cloth, which is employed to hold back the flaps while the bone is being sawn off.

b. A hook or hoe-like instrument of metal, hard rubber, or horn, to hold back masses of flesh or anything obstructing the view while operating on deep-seated organs.

2. (*Fire-arms.*) A device by which the metallic

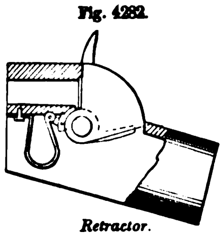
Fig. 4281.



Cartridge-Retractor.

cartridge-cases employed in breech-loading guns are withdrawn after firing. A lug or prong rests behind the flange of the cartridge and withdraws the spent shell when the breech is opened. In Fig. 4282, the positive movement of the notched extractor-plate loosens the shell from the bore, and after passing a certain point a spring comes into play, and gives a sudden impulse to the shell, which throws it clear of the fire-arm.

Fig. 4282.



Retractor.

Re-trench'ment. (*Fortification.*) *a.* A *traverse* or defense against flanking fire in a covered way or other portion of a work liable to be enfiladed.

b. A breastwork and ditch behind another defensive work.

c. An interior rampart or defensible line to which a garrison may retreat to prolong a defense.

Re-tro-ver'sion-in'stru-ment. (*Surgery.*) An instrument for rectifying an entire or partial inversion of the womb.

Sims's uterine repositor consists of a short metallic sounder, rotatable on a long shaft, through which runs a rod, by means of which the sounder may be fixed at any angle after introduction *in utero*, and the uterus restored to its normal position.

Ret'ting, Rot'ting, Rat'ing. (*Fiber.*) Steeping of flax or hemp, for the purpose of loosening the fiber from the *boon* and woody portion by the softening of the gummy portion which binds them.

Flax, after the removal of the bolls and seed by *rippling*, is bound in sheaves and immersed in water, the sheaves being packed loosely and resting on their butts. They are covered with sods, grass side down, or by straw and poles. The water should be soft, and in gentle motion. Fermentation softens the gum, which binds the fibers and loosens the *hare* from the *bark* and *boon*.

The process having continued till the fibers part from the *boon* (the pith or internal woody portion), the bunches are raised, drained for twenty-four hours, and then spread on the grass to dry and get wet alternately; the showers, sun, and air completing the preparation of the fiber for the mechanical treatment, — the *brake* and the scutcher. This exposure to weather is termed *grassing*.

The time occupied in *retting* is from six to twenty days, according to temperature.

Dew retting is accomplished by exposing the flax stalks to the weather, without steeping, the sun, showers, and air rotting the woody portion and washing away the mucilage.

Schenck's retting apparatus, 1851, consists of circular vats, in which the flax is placed, being kept down by a weight while it is swelled by water maintained at a heat of 90° by the introduction of steam. Passing to the acetous fermentation, the mucilage is rendered perfectly soluble and is run off, the flax being then removed and dried. The process takes about sixty hours. The flax is exposed to the air upon frames or dried by steam heat.

Bower's retting process (English) consists in alternately steeping and rolling the stalks, so as to soften and press out the mucilage by the alternate process.

Caustic ammonia, or other salt, is added to the rain water, in which the plant is steeped. (Ammonia, 1 pound; water, at 90° to 120°, 150 pounds.) The process takes about thirty hours.

Another process consists in the repeated application of an alkaline solution in a vessel exhausted of air. This is said to take but a few hours. Heat is probably applied.

The process with hemp is substantially similar to the water-retting of flax.

The stalks in bundles are steeped in running streams until the cellular portion is rotting, the gummy so much softened as to wash away, and the woody so far loosened as to readily fall away from the fiber when the stalk is dried and operated upon by the brake.

Re-turn'-flue Boil'er. (*Steam-engine.*) A steam-boiler in which the heated gases return through a flue in the water space, after passing through a *direct* flue, or alongside of the boiler. See STEAM-BOILER.

Re-turn'-valve. A valve which opens to allow reflux of a fluid under certain conditions. In some cases it is merely an overflow-valve which allows excess of liquid to return to a reservoir.

Re-veal'. (*Carpentry and Masonry.*) The vertical return or side of an aperture, chimney, doorway, or window.

In a chimney it is equivalent to the *jamb*, or, when beveled, the *coving*.

In windows the *reveal* is the outside-return, or the space between the window-frame and the exterior arris.

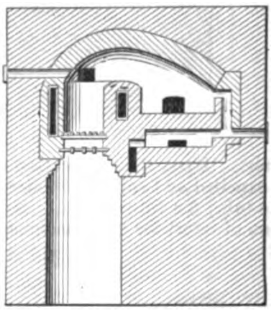
Re-ver'ber-a-to'ry-fur'nace. (*Metallurgy.*) A furnace in which ore, metal, or other material is exposed to the action of flame, but not to the contact of burning fuel.

The flame passes over a *bridge* and then downward upon the material, which is spread upon the *hearth*.

Seneca credits Democritus with the invention of the reverberatory-furnace.

The reverberatory is a very usual form of furnace, and is used in the treatment of many metals. See list under FURNACES; also PUDDLING-FURNACE.

Fig. 4283.

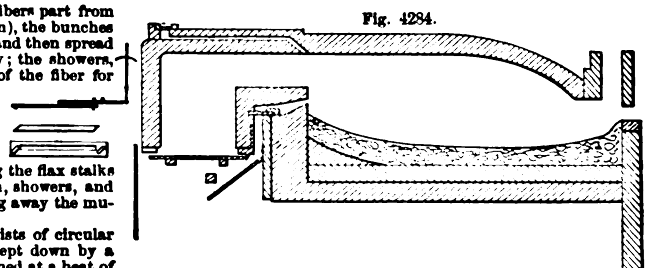


Reverberatory, with Water-Boshes.

Fig. 4283 is a reverberatory, with water-chambers around the fire-box and in the fire-bridge.

In Fig. 4284, air is heated by contact with the walls and introduced into the metal chamber in converging currents the full width of the throat.

Fig. 4284.



Reverberatory with Air-Ducts.

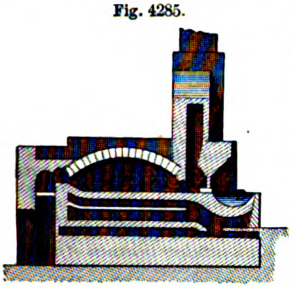
The reverberatory-furnace for copper has a furnace-chamber, hearth, two tuyeres, and two cisterns, into which the molten results of the process are discharged.

The *sole* of the chamber is covered with a composition of clay and pounded charcoal, and the charge of black copper laid upon it. The furnace is filled with wood and lighted, and when the metal is melted, a blast from the two tuyeres *t t* is made to spread over the surface of the metal in chamber *A*, oxidizing the sulphur, lead, and iron. The slags are raked off by the door *D*. Red scoriæ are formed containing suboxide of copper, which affects the malleability of the resulting metal. The operator withdraws a small quantity of metal from time to time, and tests it under the hammer to judge of its condition.

The metal is flowed from the hearth to the cisterns *B B*, and water thrown on the surface, producing a congealed scale of red metal. This is removed, and the process repeated until the metal is all reduced to the form of blistered scales or plates. See CALCINING-FURNACE, Fig. 1023; COPPER-FURNACE, page 618.

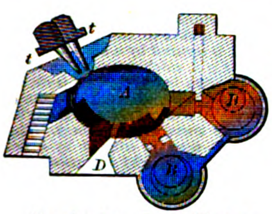
Re-verse'. The back of a coin; in contradistinction to the obverse, or face.

Fig. 4285.



Re-versed′ Arch. An arch with its convexity downward. An *inverted* arch.

Re-versed′ Curve. (*Railway Engineering.*) When a curved part of the track, instead of terminating in a tangent, joins another curving in an opposite direction, the two are said to form a reversed curve.

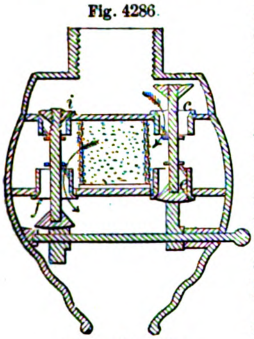


Reverberatory Copper-Furnace.

Re-versed′ O-gee′. (*Architecture.*) The *cyma reversa*, a molding composed of two circular arcs, the upper convex and the lower concave to the surface from which it projects.

Re-verse′-valve. (*Steam-engine.*) A valve in a steam-boiler opening inward to the pressure of the atmosphere when there is a negative pressure in the boiler. A vacuum-valve.

Fig. 4286.

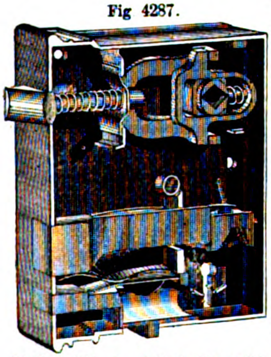


Reversible Filter.

Re-vers′i-ble Fil′ter. One through which the fluid may flow in either direction. In that shown, the filtering material is inclosed in a porous cylinder, and between two diaphragms in the chamber. Valves *c e i f* have their seats in these diaphragms and open in reverse directions; either may act as the inlet or outlet, according to the way the water flows.

Re-vers′i-ble Lock. A lock which may be applied to a door hinged to the jamb of either side, or opening either inward or outward. This involves turning the latch-bolt over, so that its beveled edge may slide freely over the catch, without requiring the knob to be turned in order to close the door.

Fig 4287.



Mallory, Wheeler, & Co.'s Reversible Lock.

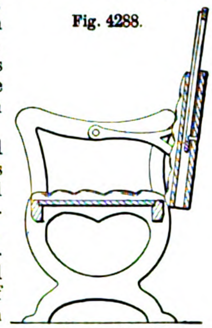
In Mallory, Wheeler, & Co.'s lock (Fig. 4287), this is effected by simply pulling the bolt forward until it clears the notch in the rim, and turning it half round.

Re-vers′i-ble Mouth-bit. (*Menage.*) A bit having a rule joint; when in one position it works the same as the Pelham, while, if reversed, it becomes a stiff-mouth bit.

Re-vers′i-ble Plow. (*Agriculture.*) A plow whose cutting apparatus is capable of being reversed, to throw the furrow slice in either direction, as required. See SIDE-HILL PLOW.

Re-vers′i-ble Seat. One for railway-cars, so as to be laid over on either side, according to the direction in which the car is traveling. In Fig. 4288, the head-rest is padded, and traverses the seat-back, so as to be drawn upward from either side.

Fig. 4288.

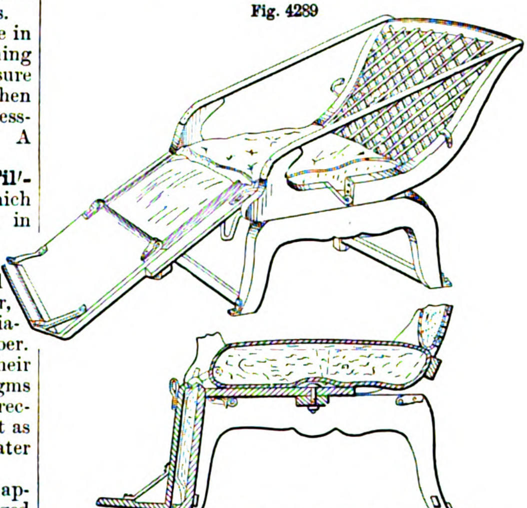


Reversible Car-Seat.

Fig. 4289 has a hinged back, is reversible on its frame, and has hooks and flexible side-straps for supporting the arms of the sitter.

Re-vers′ing. (*Engraving.*) Obliterating engraved lines on plate by means of blows of a bare hammer on the engraved plate, whose back rests on a sheet-lead covering to the anvil. The reaction of the lead causes it to rise in ridges corresponding to the engraved lines,

Fig. 4289

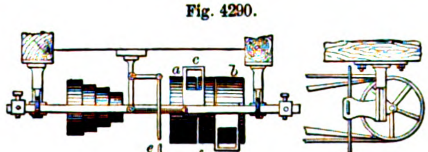


Reversible and Reclining Seat.

and to drive the thin plate before it, filling up the cuts in the face of the plate, and making a corresponding concavity in the back.

Re-vers′ing-coun′ter-shaft. (*Machinery.*) One which may be rotated either way for changing the direction of motion in the machine driven by it. One of the pulleys *a b*, which are loose on the shaft, carries a straight and the other a crossed belt pass-

Fig. 4290.



Reversing-Countershaft.

ing through the forks *c d*; on moving the lever *e* to the right or left, either belt may be transferred to

the fast pulley *f*, causing it and the countershaft on which it is keyed to turn in either direction.

Re-vers'ing-gear. (*Steam.*) The apparatus for reversing the motion of a marine or locomotive engine, by changing the time of action of the slide-valve; the eccentric being in advance of the crank for the forward motion will, if turned to an equal distance behind the crank, produce a backward motion.

Re-vers'ing-han'dle. (*Steam-engine.*) A lever which operates the valve so as to reverse the action of the steam. A *reversing-lever.*

In locomotives, the lever of the link-motion controls the valve entirely, both for forward and reversing motions and for throttling.

In marine engines, the reversing movement is by means of a wheel and worm acting upon a rack.

Re-vers'ing-mo'tion. An appliance by which the motion of the engine is changed from the *direct* to the *reverse*, as in the case of a crank which is caused to turn in a direction contrary to its former motion, or the driving-wheels of a locomotive to rotate backwardly.

The action of the steam is reversed before the piston has completed a given stroke, so that the parts which receive motion therefrom return on their former motion, or *back*, so to speak.

The reversing-apparatus of the locomotive, where it is most used, is the LINK-MOTION (which see).

Another common form is the eccentric-rod, whose gab-hook is attached to one or the other of the wrists on an arm keyed to the rock-shaft.

Re-vert'ing-draft. In steam-boilers, when the current of hot air and smoke returns backward on a course parallel to its former one. In contradistinction to a *direct*, *wheel*, or *split* draft.

Re-vet'ment. 1. (*Fortification.*) A facing to a wall or bank, as of a scarp or parapet.

The material depends upon the character of the work, whether *permanent* or *field* works. In the former the revetment is usually of masonry; in the latter it may be of sods, gabions, timber, hurdles, rails, or stones.

A *full revetment* is carried up the *scarp*, *exterior slope*, and *superior slope*. See PARAPET.
A *demi-revetment* is when a portion only of the *rampart* is revetted.
A *rectangular revetment* is one in which the vertical walls have an equal thickness throughout.
A *leaning revetment* has a wall of even thickness, sloping toward the bank.
A *sloping revetment* is thicker at the base, the back vertical.
A *counter-sloping revetment* has a sloping back and vertical face.
A *hollow revetment* has a vaulted or defensive gallery in the rear.
A *counter-arched revetment* is similar to the hollow, having a gallery with *embrasures* or *loop-holes*.

2. (*Civil Engineering.*) A *retaining* or *breast wall* at the foot or on the face of a slope. See RETAINING-WALL; BREAST-WALL; DIKE; SEA-WALL.

Re-vise'. (*Printing.*) The second proof submitted to the author, in order that he may examine whether the corrections have been made.

The *first proof* is for the office reader.

The second, or *clean proof*, for the author.

The *revise*, for the author.

Re-volv'er. 1. (*Weapon.*) A fire-arm having a revolving barrel or breech cylinder, so as to discharge several loads in quick succession without being reloaded. In some pistols the barrel has a plurality of bores, in which the charges are inserted and from which they are fired; more commonly, as in Colt's, the weapon has a cylinder at the base of the barrel, containing several chambers, generally six, in which the loads are placed, and all are fired through the single tube which constitutes the barrel; in all the rotation is caused by devices actuated by the lock mechanism.

The principle is not new, but it was first made a practical success by the late Colonel Samuel Colt.

Colt's revolving pistol is shown in section at *D*, and the cylinder and revolving mechanism detached at *E*. In general construction it closely resembles the rifle. The barrel *c* is of steel and rifled. It has a socket beneath for receiving the rammer *d* with its lever *d'* and fixtures, and a longitudinal socket and transverse slot to receive and secure the cylinder-pin *e*.

The cylinder *f* is of steel, and has five or six chambers, of the same size as the barrel, or a very little larger, bored through it nearly to the rear end, leaving a sufficient thickness of metal to insure against bursting. Behind and entering each chamber a cavity is made, at the base of which is a screw-threaded orifice, entering the cylinder, into which a cone is screwed.

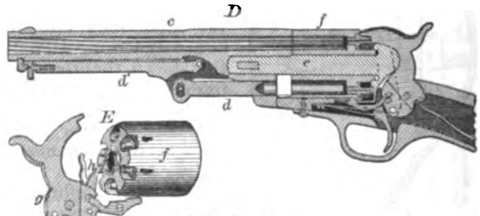
In another hole bored axially through the cylinder, the pin on which it turns passes, one end entering a cavity in the base of the lock-frame, and the other a socket in the enlarged portion beneath the barrel, where it is secured by a key.

On the base of the cylinder *f* is a ratchet having as many teeth, five or six, as the chamber has barrels. The teeth are so arranged that when the hammer is at full cock, a chamber is directly in line with the barrel. On the surface of the cylinder are cut as many small slots as there are chambers. That which happens to be lowest at the time is entered by a bolt which is moved by the action of the lock, and is pressed into the slot by a spring, so that while in this position the cylinder is immovable.

The lock-frame is directly in rear of the cylinder, and contains the firing mechanism.

The sear and trigger are in one piece, as are also the hammer and tumbler *g*, upon which the main-spring acts directly. On the face of the tumbler is a pawl or *hand h*, which successively engages each of the teeth on the rear of the cylinder; and the tumbler has also a projecting pin which at the proper time engages the bolt that locks the cylinder, lifting it out of the slot and allowing the cylinder to rotate under the action of the hand. When the pin no longer acts upon the bolt, it is forced by the spring into the next notch which presents itself.

Fig. 4291.



Colt's Revolver.

The operation is as follows: The chambers having been loaded by inserting a cartridge successively in each and forcing it home by the rammer and its lever, and capping each cone, the hammer, supposed to be resting on one of the cones, is drawn back; this causes the pin on the tumbler to disengage the bolt from the lowermost slot in the cylinder, and the hand engages a tooth and rotates the cylinder $\frac{1}{5}$ or $\frac{1}{6}$ of a revolution; on arriving at full cock the pin is disengaged from the bolt, which then falls into the next slot and locks the cylinder; the weapon may then be discharged by pulling the trigger.

In those pistols which are designed for firing metallic cartridges, the cartridge is inserted at the base of the cylinder, the case being afterward pushed out by a device analogous to the rammer just described.

Fig. 4292 shows a group of Colt's revolvers.

A, the revolver musket for infantry.

B, a revolving rifle for sporting.

C, a revolver-carbine.

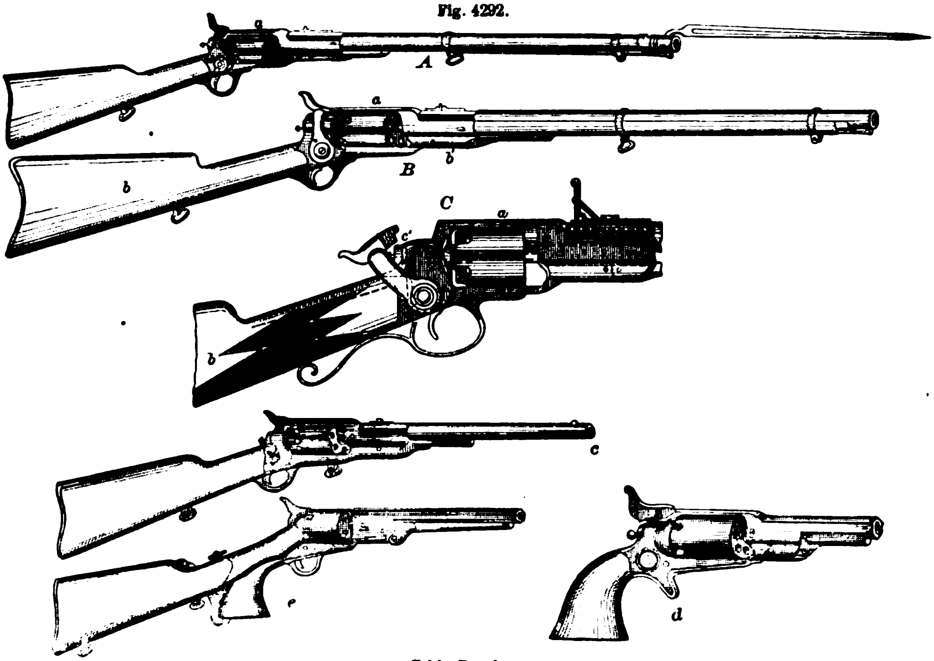
d, a pistol.

e, a pistol mounted on a supplementary stock for shooting from the shoulder.

Colonel Colt obtained his first patent in 1835, but his weapon was not perfected until 1845. On visiting England, he undertook to investigate the origin of repeating fire-arms, and the result of his researches was that arms similar in principle to his own revolver had been invented four centuries before.

In the Tower of London he was shown a match-lock gun, dating back to the fifteenth century, and closely resembling, in the principle of its construction, the revolver of the present day. It has a revolving breech with four chambers, mounted on an axis fixed parallel to the barrel, and on that axis it may be

Fig. 4292.

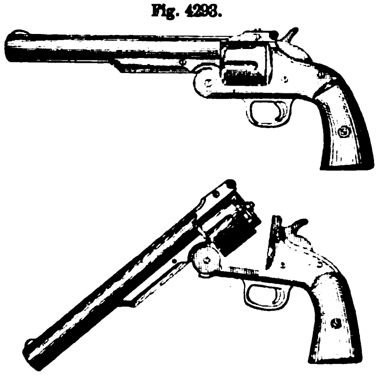


Colt's Revolvers.

turned round, to bring any one of the four loaded chambers in succession in a line with the barrel, to be discharged through it. There are notches in a flange at the fore end of the revolving breech to receive the end of a spring, which is fixed to the stock of the gun, for the purpose of locking the breech when a chamber is brought round into the proper position. The hammer is split at the end, so as to clasp a match, and to carry its ignited end down to the priming powder, when the trigger is pulled. Each chamber is provided with a priming-pan that is covered by a swing lid, and, before firing, the lid is pushed aside by the finger, to expose the priming powder to the action of the lighted match. In the lower armory was a specimen of a repeating fire-arm of a more recent date, though still very ancient, and presenting considerable improvement on the preceding one. It has six chambers in the rotating breech, and is furnished with a barytes lock and one priming-pan, to fire all the chambers. The priming-pan is fitted with a sliding cover, and a vertical wheel with a serrated edge projects into it, nearly in contact with the powder in the pan. To this wheel a rapid motion is given by means of a trigger-spring, acting upon a lever attached to the axis of the wheel, and the teeth of the wheel strike against the barytes, which is brought down, previously to firing, into contact with it, and the sparks thus emitted set fire to the powder in the priming-pan, and discharge the piece. In this instance, also, the breech is rotated by hand.

In Smith and Wesson's revolver (Fig. 4293), the

Fig. 4293.



Smith and Wesson's Revolver.

cylinder is rotated in the usual way by a click operated by the hammer in cocking and firing.

The cylinder is connected with the barrel, which is pivoted to the lower metallic part of the stock, so that by setting the hammer at half cock, raising a spring-catch *a*, and depressing the muzzle, the bottom of the cylinder is turned up to receive the metallic cartridges. When the muzzle end of the barrel is thrown upward, the spring-catch reëngages in the back plate, and the pistol may be fired.

Fig. 4294 shows six revolvers which are interesting in the history of that fire-arm.

a is a matchlock of the fifteenth century, in the Museum of the Tower of London. It has a revolving breech with four chambers, which rotates on an arbor parallel to the barrel. The chamber is turned by hand.

b is an arquebuse, with six chambers, each of which carries its own pan for priming powder. A movable plate covers the powder-pans and exposes them serially to the match as a given chamber comes in line with the barrel. This is an Oriental piece, and was given to Mr. Forsyth by Lord William Bentwick, the governor-general of India.

c is an arquebuse, in the Tower of London, with six chambers in a revolving breech, and a flint lock. This has a sliding plate over the powder-pan. The turning of the breech is automatic.

d is the arm of John Dafts, of London, and has six chambers.

e is Elisha Collier's arm, patented in the United States in 1818. The charge-cylinder has five chambers, and is turned by hand. The cylinder is held between two plates, of which the lower presses the cylinder toward the barrel, and the upper plate closes the chambers. The rod serving to charge the chambers is placed in the stock. The hammer carries a magazine of priming placed in the stock. This gun is No. 1260 of the collection in the Museum of "St. Thomas d'Aquin," in France, where also are several other ancient arms with revolving-chambered breeches.

f is a revolving-chamber flint-lock pistol at Woolwich.

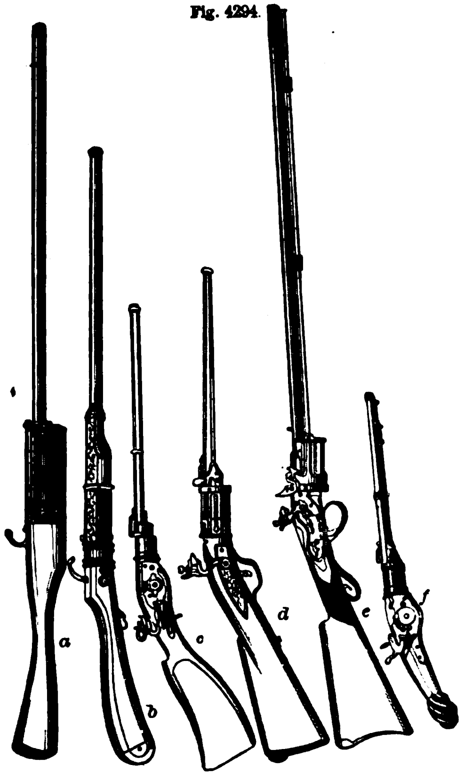
They are thus described in Turgan's "Études sur l'Artillerie Moderne," Paris, 1867. The cylinders are all revolved by hand, and not by special mechanism. Three are with matches, and were made in the beginning of the seventeenth century. One (No. 1251) is a small flint-lock hunting arquebuse: the cylinder has eight chambers. The vent is closed by a sliding cover; a spring with a hook stops the cylinder at the time it is in line with the barrel.

1252 (of the same collection) is an arquebuse with a match; the cylinder has five chambers, and turns upon an axis parallel with the barrel. It has a pan for each barrel.

1253 is a five-charge match arquebuse, having but one pan, of which you renew the priming at each shot.

1254 is a German musket of the middle of the seventeenth cen-

Fig. 4294.



Revolvers (from the Fifteenth Century to 1818).

tury. It has a wheel-lock. It has three chambers, and turns on an axis parallel with the barrel.

1255 is a five-chambered French flint-lock gun of the eighteenth century.

1256 is a gun of the same date, with six chambers.

2. (*Husbandry.*) A hay or stubble rake whose head has two sets of teeth projecting from opposite sides in the same plane. The set in advance having collected a load, the rake is tipped, making half a revolution, discharging the load and bringing the other set of teeth into action. See Fig. 2454, page 1082.

Re-volv'ing. Having a motion in an orbit, as that of a planet around the sun ; the cylinder of a *revolving-cylinder* steam-engine around the shaft ; the *planet-wheel* of the sun-and-planet motion around the sun-wheel.

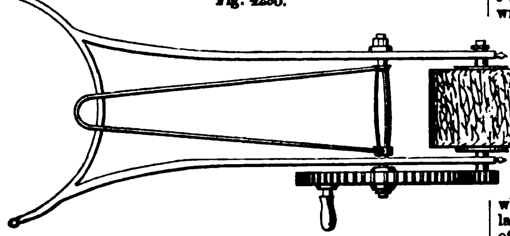
The terms *rotary* and *revolving* should not be confounded, as they are needed in their specific senses.

Rotation on an axis, as a carriage-wheel, a sun-wheel.

Revolution, as cited above.

Re-volv'ing-boil'er. (*Paper-making.*) A boiler for paper-stock or pulp, rotating on trunnions, so as to agitate the contents and expose the stock fully to the hot-water, steam, chemicals, etc. See PULP-BOILER ; PULP-DIGESTER, etc.

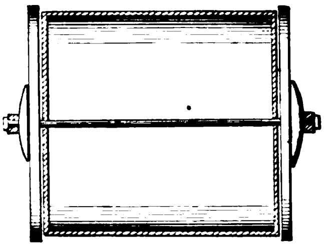
Fig. 4295.



Revolving-Brush.

Re-volv'ing-brush. A mechanically rotated brush for the hair or for sweeping. The example is intended for barbers' use ; the frame has a curved portion resting against the person of the operator, and an elastic loop passing around his neck, and is turned by a hand-crank and spur-gears.

Fig. 4296.



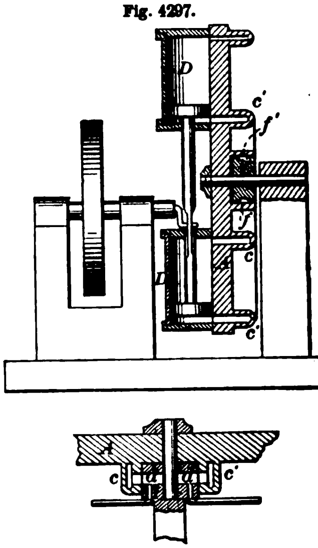
Revolving-Car.

Re-volv'ing-car. One which rolls as it travels. In the example, a cylindrical receptacle is attached to an axle supported in a frame by two wheels, which run loosely on the axle to allow them to turn more easily. Each frame has a tongue, and two or more cars can be attached to each other.

Re-volv'ing-cyl'in-der Steam-en'gine. One whose cylinder is mounted on trunnions and is caused to rotate by the reciprocation of the piston, in contradistinction to the rotary engine, in which the pistons rotate on an axis within a steam drum.

The sectional view (Fig. 4297) exhibits an engine of this class, having a fly-wheel *A* with two cylinders *D D* rigidly attached to it and placed opposite each other in a radial line. These cylinders have a common piston-rod, which is attached at its center to a crank-pin in such a manner that every revolution of the fly-wheel *A* caused by the action of the steam in the cylinders produces two revolutions of the crank.

Fig. 4297.



Revolving-Cylinder Steam-Engine.

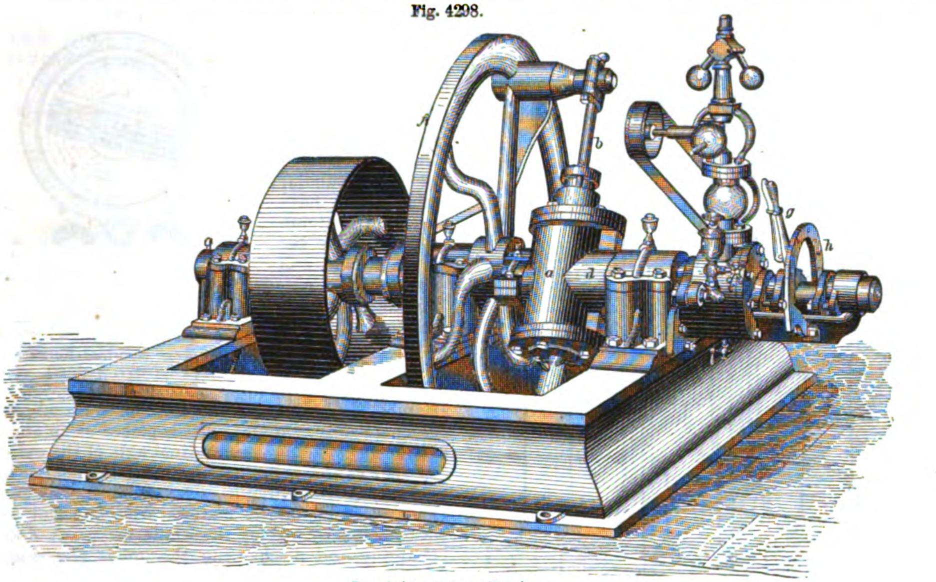
The stationary disk-valve *I*, with ports *d d'* and grooves *f f'*, and pipes or channels *c c'*, control the admission and exhaust of steam.

In Scott and Morton's steam-engine (Fig. 4298), the cylinder *a* is mounted on trunnions *c d*, and the piston-rod *b* is connected to a wrist-pin on the fly-wheel *f*. The trunnion *c* is journaled eccentrically in the hub of the fly-wheel, so that each revolves independently on its own axis. Previous to starting the engine, the piston is placed at half-stroke on one side of the fly-wheel center. Steam is admitted to and exhausted from the cylinder through ports in the trunnion *d*. *e* is the steam-chest.

The valve motion is controlled by the lever *g*, by which the engine is started or reversed, and by moving it back or forth on the arc *h* the lap of the valve is changed.

In Kipp's revolving-engines the exterior cylinder, to which a belt may be directly applied, it being surrounded by a lagging for that purpose, is caused to rotate by the reciprocation of two pistons with duplicate heads in cylinders whose axes are at right angles to each other. The piston-heads *a a'* are con-

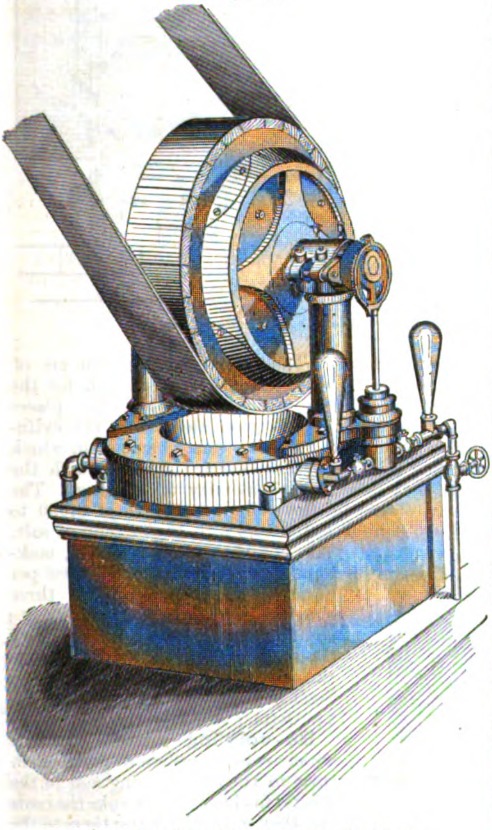
Fig. 4298.



Revolving Steam-Engine.

nected, as are also $b\ b'$, by the pieces $c\ c\ c'\ c'$. Yokes $d\ d'$ connect these with a crank e on the main shaft of the trunk. Steam is

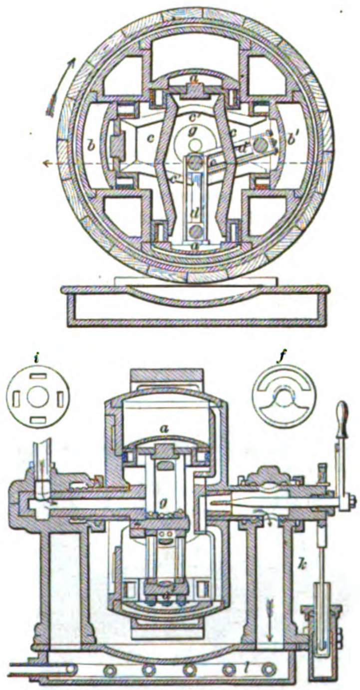
Fig. 4299.



Kipp's Revolving-Engine (Perspective View).

admitted through the valve f to the central space g, which serves as a steam-chest. The arrangement of the ports is shown at i. The drum is mounted on trunnions, through one of which the steam enters, the other serving to exhaust through one of the hollow

Fig. 4300.

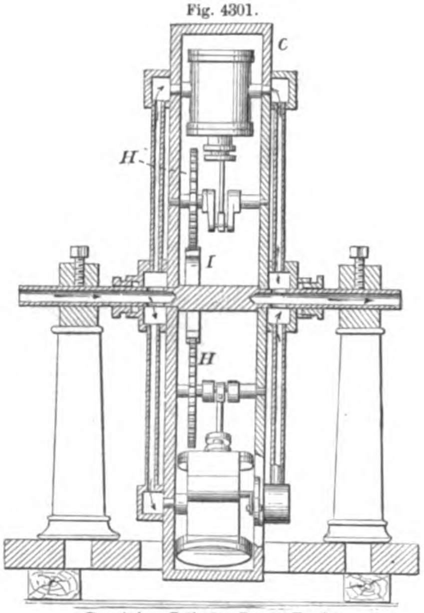


Kipp's Revolving-Engine (Sections).

pillars k into the feed-water heater l; an eccentric on the main shaft also operates the feed-water pump.

In Fig. 4301, the drum C rotates in bearings, the steam passing in and out at the respective trunnions. The cylinders oscillate in bearings in the heads of the drum, and revolve with it.

Fig. 4301.

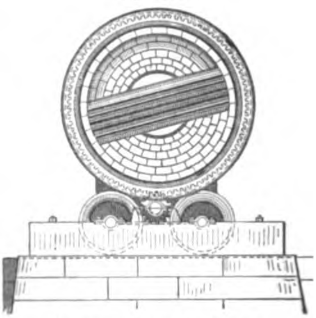


Revolving-Cylinder Steam-Engine.

The reciprocating pistons are connected by cranks to planetary gears *H H*, which mutually and severally engage a fixed sun-wheel *I* on the central axis. Power is transmitted by a belt on the drum.

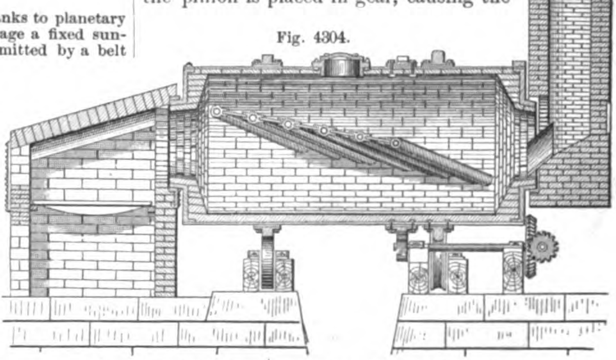
Re-volv′ing-fur′nace. The Brückner revolving-furnace, for chloridizing, desulphurizing, and roasting ores is shown in Figs. 4302, 4303, and 4304. It is designed for roasting ores with salt, and is a horizontal cylinder, constructed of boiler-plate iron and lined with fire-brick. It is 12 feet long and 6 feet in diameter, supported on rollers, on which it is rotated by gearing. One end of the cylinder communicates with a brick fireplace, while the opposite end is let into the stack so that the flame from the fireplace passes through the interior of the cylinder. Within the cylinder there is an iron diaphragm or partition protected by fire-proof material and running longitudinally through the greater part of its length. It is made in sections, which are held in grooves that are formed in the tubular ribs, which have open ends extending outward beyond the side of the cylinder, permitting the passage of air. When the several sections are in place, the entire partition or diaphragm has the form of a rhomb, whose ends are obtuse angles. It is placed at an angle of 10° or 15° with the longitudinal axis of the cylinder, so that as the cylinder containing the charge is revolved, the diaphragm causes a continuous passing and repassing of the material from one end to the other, thereby mixing the whole mass. A door for charging and discharging the ore is placed on the surface of the cylinder opposite the partition. The outside of the cylinder has flanges which rest on the rollers, and a toothed rib, with which the pinion is placed in gear, causing the whole to revolve. The fireplace and fire-flue are of brick or stone, with funnels large enough for the ends of the cylinder, which may fit into their places easily and revolve. Between the end of the cylinder and the stack there is a dust-chamber, in which the fine material that is carried through with the draft may have an opportunity of settling. The charge of ore for the cylinder consists of 3,000 to 4,000 pounds, with from 6 to 10 per cent of salt. The cylinder revolves slowly, making only one or two revolutions per minute; it consumes about three quarters of a cord of wood per day; the chloridation is said to be very thoroughly effected. See also ROASTING-FURNACE; SILVER PROCESS; DESULPHURIZING-FURNACE; SILVER-MILL; SHAFT-FURNACE.

Fig 4303.



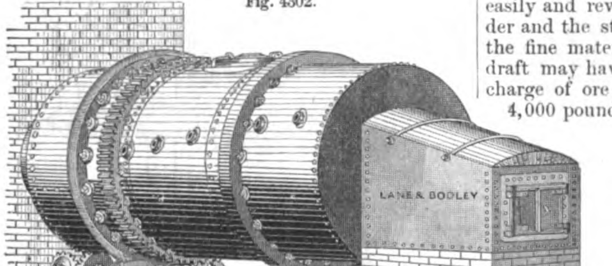
Brückner Roasting-Furnace (Transverse Section).

Fig. 4304.



Brückner's Revolving-Furnace (Longitudinal Section).

Fig. 4302.



Brückner's Revolving-Furnace (Perspective View).

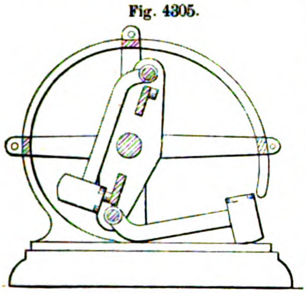
Re-volv′ing-grate. 1. One which exposes different portions in turn to the feed-opening and to the greater fire heat, so as to coke the coals and then gradually bring them to the point where the fire is more urgent.

2. An ore-roasting furnace with a horizontal revolving-hearth. See ROASTING-FURNACE.

Re-volv'ing-ham'mer. A hammer revolving with a shaft.

In Fig. 4305, the apparatus consists of an armature revolved by a crank which carries two hammers, whose handles, hinged respectively upon axes at the ends of the armature, may fold back upon the armature and upon opposite sides thereof in such manner that the hammers will rest upon supports attached to said armature lying within or nearly within the orbit of the axis to which the handles are secured, and the circle described by the armature. A rim or guard of unequal but proper curvature, which lies in the orbit of revolution of the armature, prevents the hammer from being thrown from its support by centrifugal force until it shall have passed beyond a plane projected vertically through the axis of the armature.

Fig. 4305.

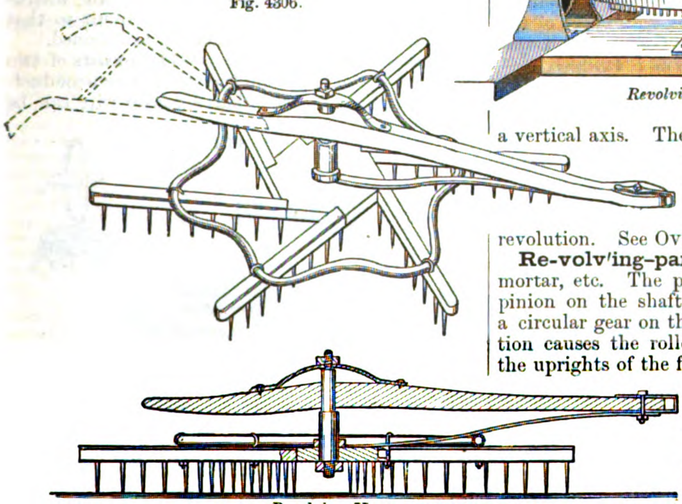


Revolving-Hammer.

Re-volv'ing-har'row. One which rotates in a plane parallel to the earth's surface, to assist the dragging action of the teeth. In Fig. 4306, the beams that hold the teeth are attached at their inner ends to a hexagonal central hub of iron, provided with mortises in each of the six sides. See also HARROW.

Re-volv'ing-light. One character of light as displayed from a lighthouse. It is one of the forms

Fig. 4306.



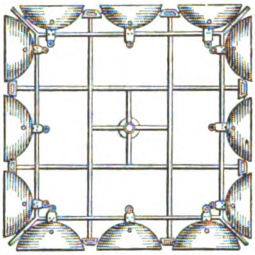
Revolving-Harrow.

of interrupted lights; the others are termed *intermittent* and *flashing*. Each of the three is distinguished from the *fixed*, whose beams are constant. The *fixed*, *revolving*, *intermittent*, and *flashing* are each capable of variation as to *color* and *number;* in the latter respect as *single* and *double*.

The characteristics above cited are variously combined, as, *revolving white*, *revolving red and white*, *revolving red and two whites*, *double fixed*, *double revolving white*, etc., etc.

The revolving light is produced by the revolution of a frame with three or four sides, having reflectors of a larger size than those used for a fixed light, grouped on each side with their axes parallel. The revolution exhibits once in one or two minutes, as may be required, a light gradually increasing to full strength, and then decreasing to total darkness.

Fig. 4307.



Revolving-Light.

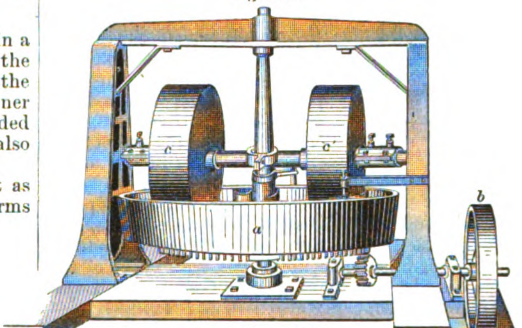
The *intermittent* has a steady light for a short time, and a sudden eclipse, forming a dark interval.

The *flashing* is a revolving light in which the light is always visible, but alternates in power, the light rising and sinking at intervals of five seconds. See LIGHT.

The reflectors are attached to a square reflector-frame, having an upright central shaft on which the apparatus turns. This is supported by a socket below and a bridge-piece above. It is rotated by clock-work and gearing. When the light is alternate *red* and *white*, the lamp chimneys of the lights on the respective sides are of red and white glass. When two white lights alternate with one red, or vice versa, the frame is triangular or hexagonal, and the lights on the respective sides are suitably arranged for the sequence of colors.

Re-volv'ing-ov'en. One having pans which revolve on a horizontal axis, or a horizontal hearth on a vertical axis. The object is to pass the bread once around within the time required for baking, taking off a batch of loaves and putting on a batch of dough at each portion of a revolution. See OVEN.

Fig. 4308.



Revolving-Pan Mill.

Re-volv'ing-pan Mill. A mill for grinding mortar, etc. The pan *a* is caused to rotate by a pinion on the shaft of the pulley *b*, which engages a circular gear on the bottom of the pan. Its rotation causes the rollers *c c'*, journaled in bearings in the uprights of the frame, to revolve and comminute the material beneath, which is directed toward them by curved scrapers.

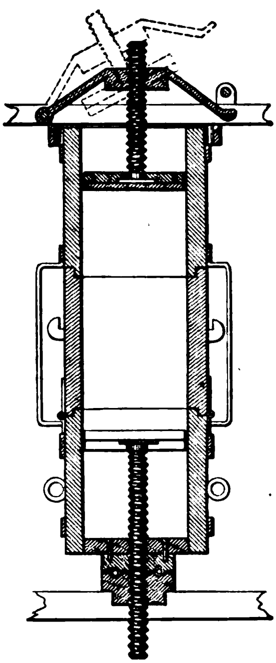
Re-volv'ing-press. One form of baling-press, in which, as the box revolves, screws acting in stationary nuts actuate the followers in the box, approaching or withdrawing them according to the direction of rotation of the box.

The press has usually but a single screw, one example of which is shown under BALING-PRESS (which see).

In the present example, the box rotates on a vertical axis, and has two followers attached to the ends of screws, one right and the other left, which screws pass through fixed nuts, one at the top and the other at the bottom of the frame, so that, as the box is rotated, the followers turn the screws and are thereby made to advance toward or recede from each other.

Re-volv'ing-sun. A pyrotechnic device, con-

Fig. 4309.



Revolving-Press.

sisting of a wheel upon whose periphery rockets of different styles are fixed, and which communicate by conduits, so that one is lighted in succession after another.

Re-volv'ing-tow'er. The revolving tower or turret, for offensive or defensive operations, was the work of Theodore R. Timby, of Saratoga, N. Y. The idea was conceived and a model made in 1841, caveated in 1843, and it was patented to him in 1862.

The original model had a base, revolving-tower, and central lookout, and the specification of 1843 involved the use of steam-power for revolution and for propulsion of the floating structure. The revolving-turret is a feature in the monitors, both as constructed by Captain Ericsson and his successors, and also by Captain Coles of the British navy, who devised a modified form of turret. Some notice has been taken of the subject under ARMOR-PLATING; GUN-BOAT; IRON-CLAD (which see). See also TOWER; TURRET.

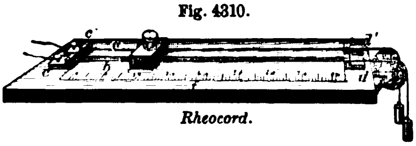
The advantages claimed for the turret over the broadside are,

1. Steadiness of carriage amidships.
2. Hight above water.
3. Greater facility of training and increased field of fire.
4. Protection to gunners, as the port can be turned out of fire.
5. Rapidity of fire, as the gun may be kept trained while the embrasure is turned out of fire.
6. That it admits of greater weight of metal being thrown on one side.
7. Advantage of position, as the gun can be pointed in any direction without regard to the lay of the vessel.
8. Allows a minimum port-hole without interference with range

Rhe'o-cord. An instrument for measuring electro-magnetic resistances. Poggendorff's (Fig. 4310) is well adapted for small resistances.

Two platinum wires *a b* are stretched on a board and held between clamps *c c' d d'* at either end. To the ends *d d'* are attached silken strings passing over

Fig. 4310.



Rheocord.

pulleys and carrying weights, which keep the wires tense. The wires are insulated from the clamps and pass through a box *e* filled with mercury, which slides on the wires and carries a vernier. When the clamps *c c'* are connected with the poles of a battery, the current from *c* passes through the wire to the box *e*, where it is transferred by the mercury to the other wire and conducted to the other pole of the battery. The distance which the current has to traverse along the wires is greater or less, according as the box *e* is caused to approach or recede from *c c'*, and is measured on the scale *f* by an index attached to the box.

The resistance of the whole length of the wires *a b* having been determined, that of each division of the scale is deduced, and one of these divisions may be employed as a unit for calculating resistances either by the differential or substitution methods.

A simple arrangement for measuring greater resistances consists of a number of short metallic bars placed at equal distances apart on a board, in such a way that their ends may be connected by the insertion of brass plugs between them. Each bar is attached to one terminal of a German silver coil of definite resistance. When the plugs are all inserted, a current will pass directly through the series of plates; but when any one or more is left out, the circuit is compelled to pass through the resistance coil or coils connected to the bar or bars thus left out of the short circuit. The sum of their resistances gives the total resistance.

A modified arrangement on the same principle is employed for measuring very great resistances. Half of each coil is in all instances wound in a direction opposite to the other, to neutralize the induction of the coil upon itself.

Rhe-om'e-ter. (*Electricity.*) A term first proposed by Peclet to designate an instrument to measure the force of an electric current. See ELECTROMETER; GALVANOMETER.

Rhe-o-mo'tor. (*Electricity.*) Any apparatus which originates an electric current, whether it be a magneto-electric current or a voltaic battery, a thermo-electric battery, or any other source whatever of an electric current.

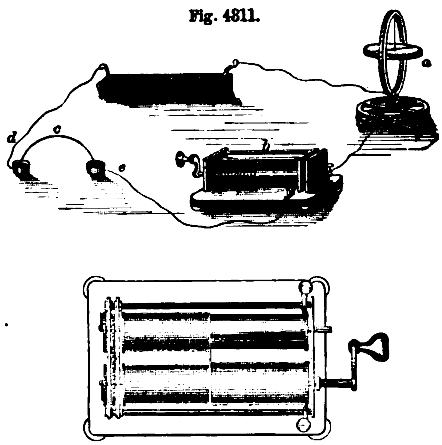
Rhe'o-phore. (*Electricity.*) A term employed by Ampère to designate the connecting wire of a galvanic apparatus as being the carrier or transmitter of the current.

Rhe'o-scope. (*Electricity.*) An instrument for detecting an electric current. See ELECTROSCOPE.

Rhe'o-stat. (*Electro-magnetism.*) An instrument for regulating or adjusting a circuit so that any required degree of force may be maintained.

Wheatstone's rheostat (Fig. 4311) consists of two cylinders, one of brass and the other of non-conducting material so arranged that a copper wire can be

Fig. 4311.



Rheostat.

wound from one to the other by turning a shiftable handle. The surface of the non-conducting cylinder has a screw-thread by which the successive convolutions of wire are isolated. Being introduced into a circuit, the wire is wound on or off the threaded cylinder by which the resistance is determined, the brass cylinder being so large that its resistance is not considered. In the upper figure, the current is

shown as traversing a galvanometer *a*, the rheostat *b*, and the conductor *c*, the resistance of which is to be measured. The whole wire being wound on the brass cylinder, the deflection of the galvanometer is noted, the conductor *c* is withdrawn from the circuit, and the ends *d e* directly connected; the amount of wire on the non-conducting cylinder when the galvanometer indicates an equal deflection, shows the strength of the resistance *c*.

Rhe'o-tome. (*Electricity.*) An instrument which periodically interrupts a current. — FARADAY.

Rhe'o-trope. (*Electricity.*) An instrument which periodically inverts a current. — FARADAY.

Rhi'no-plas'tic Knife. One for performing the Tagliacotian operation for artificial nose. See next article.

Rhi'no-plas'tic Pin. A pin used in securing an artificial to the natural base or remains of the nose.

The operation for the restoration of the nose was introduced by Gaspar Tagliacozzi at Bononia, about 1553. He cites successes of former operations in ingrafting noses, ears, lips, etc. Tagliacozzi obtained the piece for the replacement by dissection from the shoulder or arm of the patient, or a piece from some obliging person who was willing to be tied to the patient for a few weeks till the graft united, and might be severed from the original proprietor.

Liston introduced the plan of cutting the piece from the forehead of the noseless. This plan had been previously practiced among the Koumas of India, among whom the loss of the nose was inflicted as a penalty for various crimes. The brutal punishments or revenges of Europe, a few centuries since, included various mutilations, pruning off the salient members, especially those of the head, and sometimes, as in the case of Abelard, organs whose loss no skill could remedy, and whose imitation would be but an aggravation.

The "Notary's Nose," by E. About, is an amusing account of the operation for grafting an artificial nose upon the face of a man, M. L'Ambert, who is related to have had his fine Roman nose cut off in a duel with a Turk. A vagabond cat having eaten the amputated organ, the patient is reduced to a choice between the East Indian and Italian methods. The former consists in cutting a triangular piece out of the skin of the forehead, the apex at the bottom, at which point the portion retains its attachment to the brow. The flap is then turned down and twisted half round, so as to bring the epidermis outside, and its edges are sewed to the corresponding outline of the wound. The Italian method is to cut the flap from the arm, to which it is left attached at one point to keep up a vital circulation; the piece is sewed to the outline of the wound, and the arm is bound to the head till the junction is perfected.

M. L'Ambert selected an Auvergnat water-carrier, who consented to allow the flap to be cut from his arm, which was bound to the head of the patient, and so they were united for a month. The interest turns upon the quarrels of the ligatured parties and a supposed connection of the new nose with the bodily conditions of the discharged water-carrier, even after the separation of the parties. The lout becomes dissipated, and the nose is red and swollen; sick, and the nose becomes thin, pale, and attenuated; he enters a looking-glass factory and absorbs so much mercury that the notary's gold spectacles become rotten at the bridge by amalgamation; he catches a terrible cold, and "talking through his nose," as the phrase is, has a horrible Auvergnat brogue; finally, the man loses his arm by entanglement in some machinery, and the notary's nose drops off.

Rhi'no-scope. An instrument for examining the posterior nares, — the rear portion of the nostrils. A mirror, ½ to ¾ inch diameter, on a stem about 5 inches long, is introduced into the mouth. On the top of this mirror is a retractor, to hold back the palate, in order to obtain an uninterrupted view. Light is thrown in by means of a reflector, as used in laryngoscopy. See LARYNGOSCOPE.

Rho'dings. (*Nautical.*) The brass boxes for the journals of the pump-break.

Rho'di-um. Equivalent, 52.2; symbol, *Ro.*; specific gravity, 12.1; nearly infusible. It is a white, lustrous, hard, brittle metal, not acted on by acids when pure, and is used for the tips of gold pens.

Rhumb. One of the *points* on a compass-card. The circle of 360° is divided into 32 points or rhumbs, each interval comprehending an angle of 11° 15′. These are divided into half and quarter points. See MARINER'S COMPASS.

Rhus'ma. (*Leather-manufacture.*) A mixture of caustic lime and orpiment or tersulphide of arsenic, used in depilation or unhairing of hides.

Warington, finding that the arsenic was ineffective, and that the sulphide of calcium was the active agent, substituted the latter, *per se*, and found it effective in from 24 to 36 hours in softening the epidermis and loosening the hair.

Rhy-sim'e-ter. An instrument invented by Mr. A. E. Fletcher for measuring the velocity of fluids or the speed of ships. It is on the principle of the *Lind Anemometer* (Fig. 205, page 99), and of *Pitot's Tube* (Fig. 661). It presents the open end of a tube to the impact of the current, which raises a column of mercury in a graduated tube.

Rib. A bent timber or metallic bar forming a principal piece in a frame or structure, as —

1. (*Shipwrighting.*) One of the curved side timbers of a ship or boat, to which the wooden planking and the interior sheathing is trenailed or pinned. So called from their resemblance in form and object to the ribs of the human body, which are articulated in the spine and inclose the thoracic cavity.

In wooden vessels of considerable size, timber of the required dimensions and form cannot be procured to make a rib of one piece, so it is made in sections scarfed together. These are known as the *first*, *second*, and *third futtocks*, and terminate in the *top-timber*. In iron vessels, a bar of the proper size is bent into the required form.

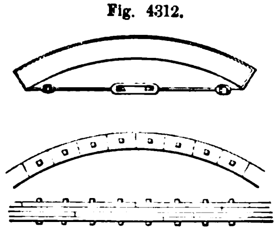
2. (*Carpentry.*) *a.* A timber arch to support a plastered ceiling.

b. A projecting or tracery molding on a vaulted ceiling.

c. A curved member of an arch center.

The rib of a bridge or roof may be of iron or wood, having an arched form and springing from abutments. The rib of a centering is of wood, and forms a part of a frame whose construction depends upon the span and expected weight.

Fig. 4312.



Built Ribs.

Built ribs, constructed on the method devised by Philibert de l'Orme, are made of several layers of planks set on edge, breaking joint, and connected by bolts. The figures exhibit a side elevation and plan, and an elevation of a rib constructed of straight-edged planks.

Laminated ribs are made of layers of plank laid flatwise and bolted together. See ARCHED BEAM, Plate III. See also ROOF, Plate LII.

Various other names have been given, as —

Decorating rib.	Ridge-rib.
Diagonal rib.	Round rib.
Intermediate rib.	Transverse rib (cross-springer).
Nerve.	Wall-rib.

3. (*Bookbinding.*) One of the ridges on the back of a book which serve for covering the tapes and for ornament.

4. (*Machinery.*) An angle-plate cast between two other plates, to brace and strengthen them; as be-

tween the sole and wall-plate of a bracket. See BRACKET.

5. (*Mining.*) A pillar of coal left as a support for the roof of a mine.

6. One of the extension rods on which the cover of an umbrella or parasol is stretched. They are made of whalebone, steel, or cane.

Ri-ba-do'quin. (*Weapon.*) A cross-bow for throwing large darts.

Rib'band. (*Shipbuilding.*) *a.* A longitudinal strip of timber following the curvatures of the vessel and bolted to its ribs to hold them in position and impart stability to the skeleton. A number of these are fastened at different distances from the keel.

b. Square timbers of the slip fastened lengthways in the bilgeways, to prevent the timbers of the cradle slipping outward during launching.

Rib'band-lines. (*Shipbuilding.*) Oblique longitudinal sections of the hull.

Rib'band-shore. (*Shipbuilding.*) A strut to support the frame of a ship while building. Their heads rest against the ribbands and their bases on the slip or dock.

Ribbed Arch. (*Engineering.*) An arch consisting of iron or timber parallel ribs springing from stone abutments.

Rib'bing-nail. (*Shipbuilding.*) A nail with a large round head with rings.

Rib'bon. 1. (*Fabric.*) A narrow fabric used for trimming.

Ribbons are of various materials, textures, and qualities. Among these are the following: *chiné, ferret, galloon, love, lustring* (lutestring), *ribbon velvet, sarsnet, satin, taffety,* etc.

The ribbon manufacture is largely carried on at Coventry, in England, and at Saint-Etienne, in France. A great number of the improvements in the different branches of the manufacture are due to the Swiss and Germans, among others the bar-loom, brought from Switzerland, in 1756, by M. Flachat, of Saint-Chamond, and the economical processes for fining velvet, introduced in 1775, by Roland de la Platiere.

The application to the bar-loom of the Jacquard machine, and of the various improvements derived from it, have resulted in the production of an admirable working instrument, with which a skilled workman is able to make everything, from simple taffetas to elaborate portraits. The ornaments vary considerably in style and arrangement. Sometimes these are purely fanciful compositions, — Byzantine, Indian, Oriental, Chinese; at others, of birds and animals, more or less approaching nature. The commonest ornaments, and generally the most successful, are borrowed from flowers. Buds, corn-ears, — fruits even, — are all suitable for composition. Birds, and some species especially, lend themselves very readily to the fancy of the designer, but quadrupeds which are able to find suitable place in an ornament are rare.

Whatever may be the nature of the design, a practical application is given to it by the card-setter, who transfers it, while enlarging the size, to a checkered sheet. This sheet assists the stamping-out machine to prepare the cardboard sheets for the Jacquard machine. The warps are made under careful supervision, and the threads composing them consist of organzines thick enough to support the strong tension necessary to the weaving. The warping requires an extreme attention, especially in the case of ribbons which are to include different kinds of web and different colors of warp. Each warping-mill is composed of a "bank," a frame slightly inclined and arched, fixed, at its two extremities, into a wooden frame. It bears a variable number of bobbins, among which are divided the organzines destined to form the web. Parallel to the bank is placed a vertical divider, on which each warp revolves when it is made. The workwoman, with her left hand, moves a crank, which transmits the motion to the divider, and with her right hand she guides the passage of the threads between the glass teeth of a kind of large toothed comb. The warps prepared in the divider are then rolled by large bobbins, called blocks, belonging to the master weaver, who is intrusted with the making of the ribbon. The threads of weft are not twisted and doubled like the organzines of the warp, but are more or less twisted, according to the nature of the tissue desired. To produce plushes in various designs, imitating either fur or the feathers of birds, especially of the peacock, they imprint on a warp the ornament they wish to reproduce, only on a wider scale, and weave it in satin; and by means of the shortening of the threads, caused by weaving, the figure is formed more or less exactly as the imprint was well or badly calculated. This satin, worked with thick silk threads, after being woven, is placed in the hands of women, who cut every length of the threads with little special tools worked with the hand. The plush then is raised or left flat according to the nature of the thread employed, and the close or loose texture of the satin. The most satisfactory results are thus obtained. Among charming combinations may be mentioned one representing, on taffetas, a peacock embroidered in relief, accompanied, on each side of the ribbon, with a plush border, happily imitating the beautiful iris eyes which glitter at the end of the peacock's feathers. A large quantity of ribbons are bordered with bands of imitation fur.

The finishing workshops, common to all the manufacturers of Saint-Etienne, give the last figuring to the different kinds of ribbons which are to receive them. Most of these figures are impressed by rolling; thus moire is obtained by passing the stuff between cylinders ranged with various cuttings. Satin, on the contrary, between smooth cylinders, the action of which compresses the threads of the warp, and gives them the polish peculiar to this beautiful material. In some special cases, the ribbons, before being rolled, are passed through a bath of starch or gum. A rigid inspection of the completed products, both on their return from the houses of the workmen and before their sale to the purchaser, weeds out all defective pieces.

Ribbons for hand-stamps are tapes saturated with an oily pigment, which becomes impressed upon an object when the stamp is brought down upon the two, which are placed in contact beneath it. It is an inky ribbon, and is used as a substitute for inking the face of a stamp.

2. (*Fiber.*) A continuous strand of cotton or other fiber in a loose, untwisted condition. A sliver.

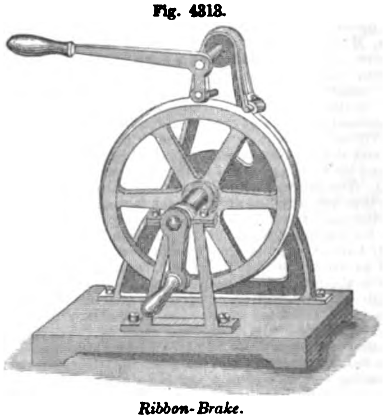
3. (*Carpentry.*) A long, thin strip of wood or a series of such strips connecting a number of parts.

4. (*Metal-working.*) A long, thin strip of metal, such as a watch-spring; a thin steel band for a belt or an endless saw; a thin band of magnesium for burning; a thin steel strip for measuring, resembling a tape-line in its size and functions.

5. (*Nautical.*) The painted moldings on a ship's side.

Rib'bon-brake. A brake having a band which nearly surrounds the wheel whose motion is to be

Fig. 4318.

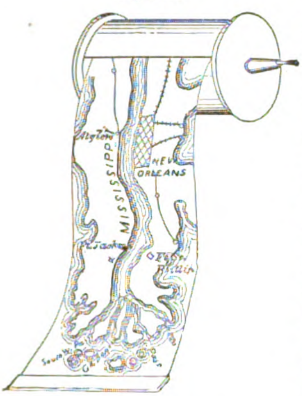


Ribbon-Brake.

checked. One end is made fast and the other is attached to the short arm of a bent lever, by means of which it may be at once applied to the greater part of the periphery of the wheel, exerting a frictional pressure proportionate to the force applied to the lever.

Rib'bon-loom. The ribbon-loom first appeared at Dantzic in 1586, and the inventor is said to have been strangled to prevent the spread of what would throw so many mechanics out of employment. It was prohibited in Holland for that reason in 1623. It is first noticed in England in 1674. In 1780, the mode of ornamentation (watering) by pressing between figured steel plates was adopted. Steel cylin-

Fig. 4314.



Ribbon-Map.

ders were afterward substituted. See NARROW-WARE LOOM.

Rib′bon-map. A map printed on a long strip which winds on an axis within the case.

Rib′bon-saw. A thin and narrow endless band of steel, one edge of which is serrated. It is stretched over two drums, such a distance apart that there is a certain length of straight saw-band between them. Motion is communicated to one of these drums, which causes the band-saw to travel with it by friction. Owing to the small width and thickness of the band, it is capable of cutting the wood to almost any curve required. See BAND-SAW.

Rib-vault′ing. (*Architecture.*) Vaulting having ribs projecting below the general surface of the ceiling to strengthen and ornament it. When the ribs radiate from a central boss or pendant, it is termed *fan-vaulting* or *fan-tracery vaulting*.

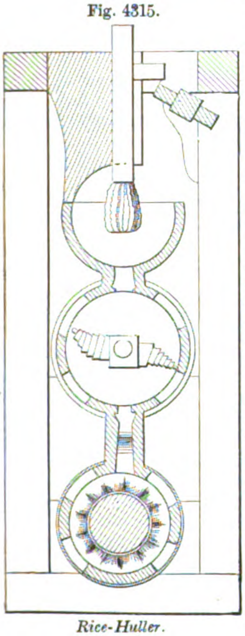
Rice-hull′er. Rice is a native of Asia, in whose warm climates it has been grown from time immemorial. Its introduction into Africa and America is comparatively recent.

The watered rice-fields of "the East" (India) are noticed by Aristobulus.

Rice was introduced into Europe by the Spanish Saracens. The same is true of cotton and sugar.

Rough rice, as it is termed in America, or *paddy*, its name in the East Indies, has an outer husk, and a thin cuticle which adheres to the pearly grain with great tenacity.

Fig. 4315.



Rice-Huller.

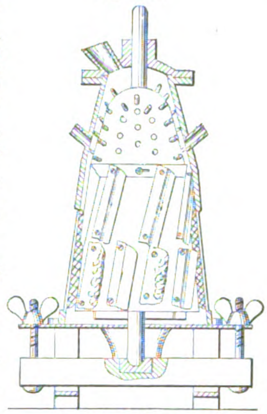
The old method of removing the hulls of rice was by pounding in mortars. These were made of pitch-pine and held about a bushel. The work was performed by the slaves of South Carolina and Georgia in addition to the day's work, a certain amount of hulling being performed by each before regular work and after it.

Machinery was constructed by Lucas, about 1780-90, which was driven by tide-power, and operated iron-shod pestles in cast-iron mortars of the capacity of five bushels each. Steam-power was subsequently introduced.

Fig. 4315 is an example of the application of machinery to the pestle and mortar huller. The grain, after a rough preliminary grinding between stones, is passed to the mortar, and is beaten by the ribbed pestle. From the mortar it passes to a horizontal cylindrical chamber having wire gauze at the sides, and containing a rotating cylinder with corrugated curved arms. From the latter the rice passes to the polishing-cylinder.

In another form of machine the cuticle is removed in a whitening-machine, which consists of a stone of coarse grit mounted like a grindstone and rotating in a sheet-iron casing, which is punched full of holes, the roughnesses projecting inward. The casing is large enough to allow a space of about one inch all round the stone, and a door in the casing allows the rice to be placed therein. The stone is rotated about 250 revolutions per minute, and a slow motion is allowed to the casing. The roughness of the stone and the casing and the mutual attrition of the grains on each other, together with the heat evolved, loosen and remove the cuticle, which passes out as a red powder through the holes in the casing.

Fig. 4316.



Rice-Huller.

Ewbank's rice-huller (English patent, 1819) recites the following series of processes:

1. The *paddy* is cleaned by sifting to remove dust and dirt.

2. The husks are rubbed off between millstones set at a suitable distance apart.

3. The grain is cleaned of its husks by a fanning-mill.

4. The grain is then pounded in mortars to remove the red skin.

5. It is placed on a screen of three distinct grades of fineness.

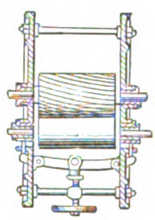
a. The upper screen allows all to pass through but the unhusked grains.

b. The second screen detains the whole rice.

c. The third screen detains the broken grains, but allows the dust to fall through.

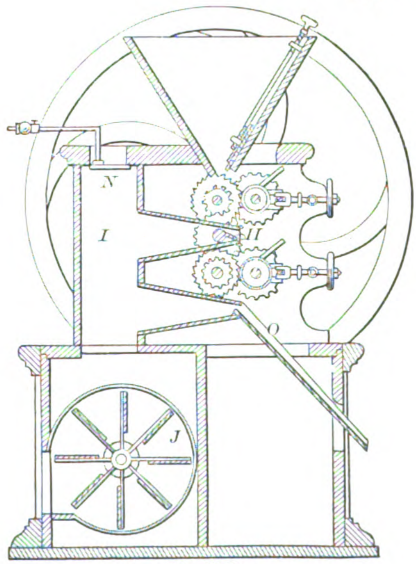
The grains unhusked in the process are conducted back to the mill.

6. The whole hulled grains are taken to the polishing or whitening machine, which consists of two cylinders placed concentrically. The exterior cylinder is stationary, and the revolving inner cylinder is covered with sheepskin having the wool on and placed on the outside. The action of the wool, the inner surface of the outer casing, and the attrition of the grains on each other, remove the remaining portions of the cuticle and polish the grain.



Wilson's rice-huller (English patent, June, 1827) specifies an inclined cylinder with inwardly projecting spokes and a slow rotation and an axial shaft with radiating spokes and a rapid rotation. The arms of the shaft occupy the spaces inter-

Fig. 4317.



Rice-Huller.

vening between those of the cylinder and conversely The rice enters at top, and is driven around in the inclined annular space, following a spiral course to its eventual discharge at the bottom.

The same plan has been adopted of late years in the United States in HOMINY-MACHINES (which see).

In yet another machine wire cards within a wire cylinder are used.

In one sorting-machine the revolving cylindrical inclined wire screen has sections with meshes of gradually increasing size. This, in connection with a blast, sorts the matter from the huller into five kinds, — *chaff*; *flour*; *small* fragments of less than half a grain; *middlings*; grain less than *prime*, but larger than *small*; *prime* unbroken grains.

Fig. 4316 is a machine which has a cone with pins, beneath which is a frustum with elastic scourers within a roughened case of conformable shape. The rough rice is fed in at top, and passes the grinding and abrading surfaces.

In Fig. 4317, the rice from the hopper passes between several pairs of rollers, in which a fluted metallic and a rubber-covered roller are placed opposite to peel the rice, which passes between them. Below each pair is a suction spout *H*, which draws the hull and chaff into the chamber *I*, allowing the grain to descend by its superior gravity. *J* is the fan which draws the chaff from the grain. *O*, the spout down which the grain descends. *N* is a valve for regulating the draft.

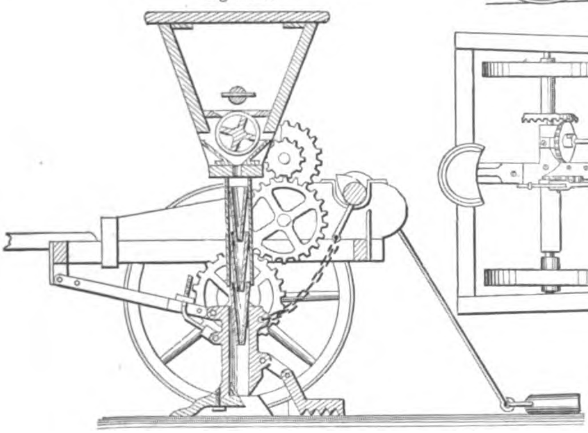
Rice-mill. A mill for removing the husk of paddy.

Rice-pa'per. A kind of paper introduced into England about 1803 by Dr. Livingstone, and named from its supposed material. It was understood to be a sort of dried pulp of rice.

It is, however, made of the pith of a leguminous plant, the *Aralia papyrifera*, which grows wild in abundance in the island of Formosa. The stem is cut into lengths of 8 or 10 inches, and the pith pushed out, much as elders are cleared of pith. This is cut into a continuous spiral ribbon, about 4 feet long, which is spread out and flattened into sheets.

Rice-plant'er. (*Husbandry.*) An implement for sowing rice. The character of the land renders

Fig. 4318.

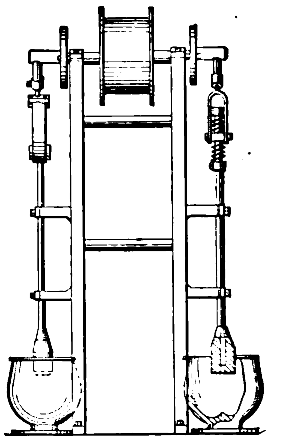


Rice-Planter.

necessary a somewhat different arrangement from the grain-drill. The seed falls through the tubular standard of the plow and is scattered by a deflecting board. The plow is followed by the coverer, which consists of a plate cast with serrations or ribs upon its lower surface. The plow is concave on its lower side, and is adjustable in horizontal inclination.

Rice-pound'ing Ma-chine'. A pestle and mortar for removing the cuticle from rough rice. The pointed elevations within the mortars prevent the pestles from crushing the particles of rice, and also cause them to spread from under the pestles, thereby producing an agitation and mutual friction of the particles.

Fig 4319.



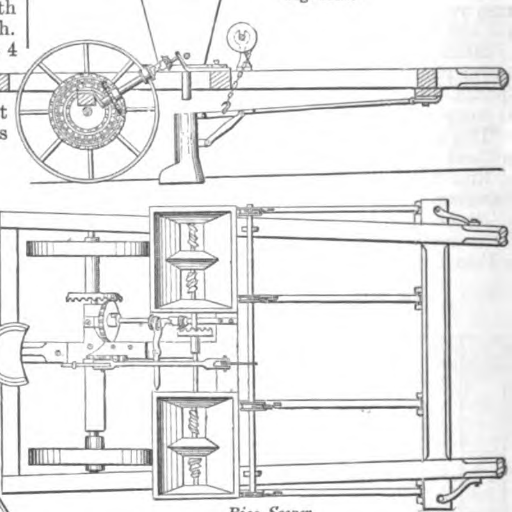
Rice-Pounder.

Rice-sow'er. (*Husbandry.*) A drill for planting rice. Fig. 4320 shows a side elevation and a top view. The seed-slides in the bottom of the hopper are worked by gearing from the main axle, and the seed drops down the conductor in the rear of the share, which opens the furrow.

Rick. (*Husbandry.*) A structure of hay or grain sheaves, having an oblong plan and a top with sloping sides to shed rain. A *stack* is round in plan, at least in the United States.

Ri'co-chet'. (*Military.*) A mode of firing with small charges and small elevation, resulting in a bounding or skipping of the projectile. In firing at a fortification, sufficient elevation is given to just clear the parapet, so that the ball may bound along the terre-plein or banquette without rising far above its level.

Fig. 4320.



Rice-Sower.

It is used with effect on hard, smooth ground against bodies of troops or such obstacles as abattis; and also upon water, either with round shot or rifle balls. It was introduced by Vauban at the siege of Philipsburg, in 1688.

Ri'co-chet'-shot. (*Gunnery.*) A bounding or leaping shot, fired at low elevation with small charge.

Rid'dle. A sieve with coarse meshes, used in preparatory separation, as: —

1. The *riddle* of a grain-separator which removes the coarser material, such as broken heads, straw, etc., from the grain; the latter is afterward separated from the chaff by the *sieves*, aided by the blast; and subsequently from the cheat and cockle by the

screen. Increasing fineness of meshes,—*riddle, sieve-screen.*

2. The coarse iron sieve which separates cinders from ashes, the larger pieces of ore from the smaller, gravel from sand, etc. See SIEVE; SIFTER.

3. (*Wire-working.*) A board with sloping pins which lean opposite ways, and between which wire is drawn in a somewhat zigzag course, to straighten it. (See WIRE-STRAIGHTENING.)

4. (*Founding.*) A coarse sieve (half-inch mesh), used to clean and mix the old floor-sand of the molding-shop.

5. (*Hydraulic Engineering.*) A kind of weir in rivers.

Rid'dlings. (*Metallurgy.*) The middle grade of broken ore which is obtained by sifting. The sizes are, *knockings, riddlings,* and *fell.* The *knockings* are the large pieces of spar and ore which are picked out. The *riddlings* remain in the sieve; the *fell* is the smallest, and falls through.

Ri'der. 1. (*Mining.*) A deposit of ore overlying the principal lode.

2. (*Shipbuilding.*) *a.* A rib within the inner sheathing, bolted through the latter into the main ribs and planking, for the purpose of stiffening the frame. The riders extend from the keelson to the orlop-beams.

b. A second tier of casks in a hold.

c. A rope which crosses another and joins it.

Ridge. 1. (*Carpentry.*) The upper horizontal edge or *comb* of a roof.

2. (*Fortification.*) The highest part of the glacis proceeding from the interior angle of the covered way.

Ridge-beam. (*Carpentry.*) A beam at the upper ends of the rafters beneath the ridge. A *crown-plate.*

Ridge-drill. (*Agriculture.*) One adapted to sow seed along a ridge which has been *listed up,* by backing up one furrow against another.

Ridge-fil'let. 1. (*Architecture.*) The fillet between two channels of a pillar.

2. (*Founding.*) The runner or principal channel.

Ridge-hoe. (*Agriculture.*) A form of cultivator for tending crops in drills.

Ridge-plow. (*Agriculture.*) A double mold-board plow, used in throwing land into ridges for certain kinds of crops.

Ridge-rope. (*Nautical.*) *a.* A rope leading from the *knighthead* to the upper part of the *bowsprit-cap,* for the safety of the men walking out upon the bowsprit in rough weather.

b. The center rope of an awning.

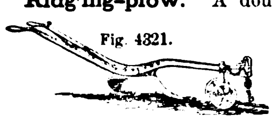
c. A safety line extended from gun to gun in bad weather.

Ridge-tile. A semicylindrical tile for covering the comb of a roof. It is 12 inches long, 10 wide, $\frac{5}{8}$ thick, and weighs about $4\frac{1}{2}$ pounds. Sometimes called a *crest-tile.*

Ridg'ing. The covering of the ridge of a building by ridge-tiles of a saddle shape.

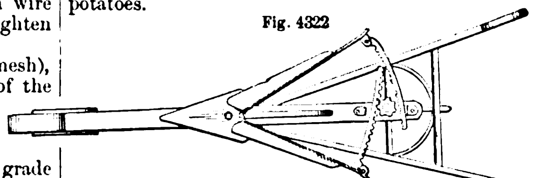
Ridg'ing-plow. A double mold-board plow, throwing the earth away and serving to ridge up land for beet-root, potatoes, or other plants sown on the ridge, and for opening water-furrows. These operations are sometimes performed by a single-breasted plow, which has to go up and down the field to accomplish the same work which this plow effects in one journey. When used for setting out land, a marker is attached for indicating the line of the next furrow. By removing the breasts and marker, it may be used for subsoiling; and again, by attaching the hoe-frame and cutters, a horse-hoe is formed, suitable for cleaning land between rows of plants sown either on the ridge or flat. By attaching to the frame of the subsoil body a set of prongs and a share, these plows are adapted for digging potatoes.

Fig. 4321.



Molding or Ridging Plow.

Fig. 4322



Ridging-Plow.

Fig. 4322 shows a ridging-plow, the wings of which are expanded or contracted by segmental racks and a pinion.

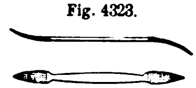
Rid'ing-bitts. (*Shipbuilding.*) Two strong upright timbers near the bows of a ship, to which the cable is secured; they extend through two decks, are connected by a cross piece and braced against the strain of the cable by horizontal standards bolted to the deck beams.

Rid'ing-part. A protuberance on the inner surface of the joint part of a scissors-blade which forms the touching portion back of the rivet, while the cutting portion is at the point of contact of the edges as they move past each other in closing.

Rif'fle. (*Metallurgy.*) An inclined trough or chute down which auriferous slimes or sand is conducted in a gentle stream, which is broken by occasional slats or by depressions containing mercury, which arrests the gold. See GOLD-WASHER; also list under METALLURGY.

Rif'fler. A file with a side so convex as to operate in shallow depressions; used by sculptors, carvers, and gun-stockers. They are made of various convexities and curvatures to adapt them to varying surfaces.

Fig. 4323.



Double-ended Riffler.

Rifflers are usually made of steel, but sometimes of wrought-iron and case-hardened, so that their shape may be modified to a certain extent by bending on a block of lead with a mallet.

Ri'fle. 1. (*Fire-arms.*) A fire-arm having the bore spirally grooved, so as to impart a rotary motion to the bullet and cause it to keep one point constantly in front during its flight.

Grooved-bored small-arms are said to have been in use as far back as 1498; these, however, do not seem to have been rifled in the proper acceptation of the term, the grooves being straight and intended merely to prevent fouling of the bore and facilitate cleaning. The grooves were made spiral by Koster of Birmingham, England, about 1620. In Berlin is a rifled cannon of 1664, with 13 grooves, and one in Munich of perhaps equal antiquity has 8 grooves. The French Carabineers had rifled arms in 1692.

Père Daniel, who wrote in 1693, mentions rifling the barrels of small-arms, and the practice was apparently well known at that time.

Rifles were early used by the American settlers in their conflicts with the Indians; and their first successful employment in civilized warfare is said to have been by the colonists in the war of the Revolution.

In the Artillery Museum at Paris is a large assortment of old rifles, comprehending a great diversity of grooves and twists. These exhibit straight grooves and grooves of uniform twist. In some the twist commences near the breech; in others, at the middle of the barrel or toward the muzzle. In some specimens, the grooves make from $1\frac{1}{4}$ to 2 turns in the length of the barrel; nearly two thirds have an even number of grooves, and

about three fourths upward of 6 grooves, varying from 7 to 12. Nearly seven eighths have grooves with rounded edges. Much the greater part of the remainder have triangular, but a few have rectangular grooves. None have grooves decreasing in depth from the breech toward the muzzle. This species of groove was introduced by Tamisier, in 1846, but is now general among the shallow-grooved arms intended for discharging expanding bullets. Tamisier also introduced the plan of increasing the twist of the grooves as they approached the muzzle.

With the earlier rifles and until a very recent period, a patch was generally used over the ball, causing it to fit tightly in the bore and take hold of the grooves. This was a somewhat precarious method; and, accordingly, the Brunswick rifle, one of the latest specially adapted for the round ball, was made with but two grooves, into which an annular rib on the ball fitted, compelling it to follow these. Lancaster effected the rotation of the ball by making it and the bore of the gun slightly elliptical in section.

To this succeeded the system invented by Delvigne, and improved by Thouvenet, Tamisier, and Minié, in which an elongated bullet, fitting loosely in the bore, is expanded, so as to fill the grooves. This permitted greater rapidity in loading, and insured the rotation of the projectile. See BULLET, page 401.

Rifling is now generally adopted in small-arms. The number of grooves is usually three. They are made very shallow, and gradually diminish in depth from the breech to the muzzle. The Swiss Federal rifle, introduced in 1848 by Colonel Wurstemburger, has eight grooves with a twist of one turn in three feet. In this the bullet is not expanded, and it has enjoyed a high reputation for accuracy. The caliber is small, .41 inch, the bullet weighing 257 grains, and the powder charge 62 grains. The plan of having studs or ridges on the bullet to engage the grooves has not been extensively adopted for small-arms. The rifle of General Jacobs, East India service, employs a bullet of this class, having four ridges corresponding to the four grooves of the rifle, and used with a patch.

In Murphy's mode, the rifling only extends four inches from the muzzle, and has its pitch left-handed to correct the slight tendency to pull the gun over to the right in pulling the trigger.

The Whitworth rifle has a hexagonal bore; the Westley Richards carbine, an octagonal bore; the Lancaster carbine, an elliptical bore, or it may be described as a spiral of oval section.

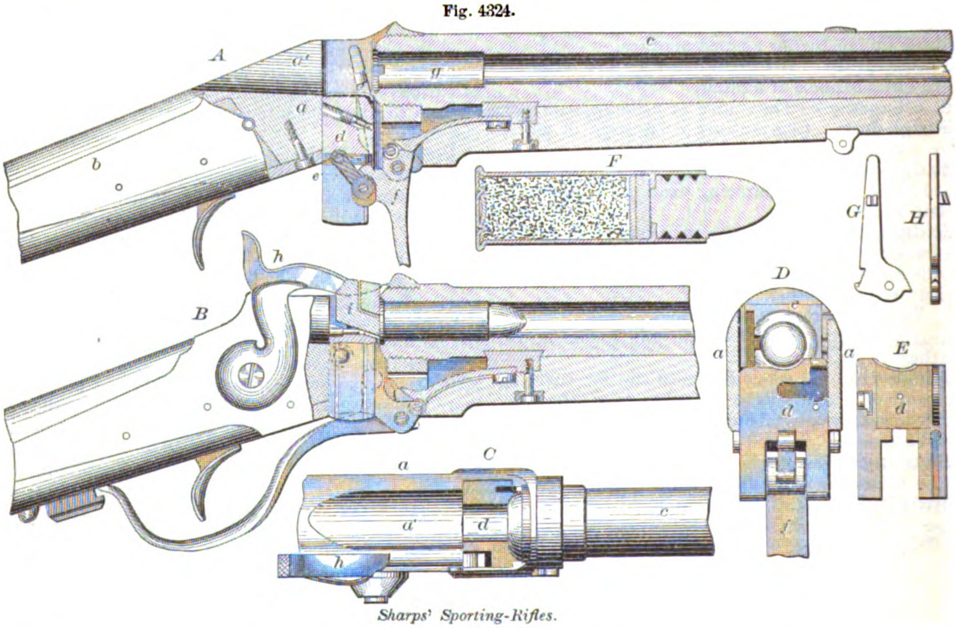
The rifling of gun-barrels in the Remington Works at Ilion, N. Y., is done by a very small cold steel chisel inserted in a long rod firmly attached to a rapidly revolving wheel, which also moves up and down a platform. The barrel is run over this rod and placed firmly in position. As the wheel revolves, the chisel in the rod cuts the rifling in the barrel; and as the wheel advances and retires very rapidly, the twist of the rifling is very elongated.

In breech-loading arms the bullet is of slightly larger diameter than the bore measured from land to land, and *slugs* so as to fill them when driven forward by the ignition of the charge.

See list of breech-loading fire-arms on pages 855–862, and illustrations, Plates XVI., XVII., XVIII. See also BULLET.

Sharps' is one of the very oldest successful guns of the breech-loading class, and the first in which a vertically sliding breech-block was employed. Originally, a paper cartridge was used, the rear end of which was cut off by the sharp forward end of the breech-block in its upward movement; a cartridge having its end closed by a thin combustible paper

Fig. 4324.



Sharps' Sporting-Rifles.

was subsequently substituted for this. At present the metallic cartridge is employed.

In Fig. 4324, *A* is a vertical section of the gun, the parts in loading position; *B*, the parts in firing position; *C*, a top view; *D*, a transverse section, with the breech-block down; *E*, front view of the breech-block, showing in the center the end of the firing-pin, and at the right-hand side the groove occupied by the cartridge-retractor shown by two views at *G H*. *F* is a metallic cartridge in section.

a is the metallic breech-piece, secured to the wooden stock *b*, and into which the barrel *c* screws; *d* is the breech-block, connected by a toggle *e* to the guard-lever *f*, and having a vertical movement

within a slot in the breech-piece *a*. The upper surface of the breech-block has a groove *a'* in line with the barrel, serving as a guide for the insertion of the cartridge into the chamber *g* when the breech-block is depressed out of the way. This is effected by throwing down the guard-lever *f*, as shown at *A*. The cartridge is then inserted, and the guard-lever brought back to the position shown in *B*, the hammer *h* having been previously set at half-cock. On depressing the lever the firing-bolt *i* is automatically moved rearward by a spur on its forward end, so as to clear the point of the bolt from the cartridge shell and rear end of the barrel. The shell is retracted by the same movement.

In order to fire, the hammer is set at full cock, and on pulling the trigger, its face comes in contact with the end of the firing-bolt, which is thrown forward, its end impinging against the base of the cartridge where the capsule containing the fulminate is placed.

The firing-bolt is so adjusted that the hammer cannot come in contact with it until the breech is perfectly closed, thus affording a security against premature discharge. The cartridge shells may be used a number of times. The exploded cap is removed, the shell cleansed, a new cap inserted, a charge of powder poured in, over which is placed a paper wad, and a lubricating wad composed of $\frac{1}{3}$ beeswax and $\frac{2}{3}$ sperm oil, and the bullet pressed home with a ball-seater.

Among the best known and most efficient arms of its class is the revolving-rifle of the late Colonel Samuel Colt, who, by the simplicity and ingenuity of his devices and his unceasing care to insure perfection of workmanship and material, first rendered the revolving system a success, and succeeded in producing a weapon which is known and used throughout the world.

In 1830, Colt invented a device "for combining a number of long barrels so as to rotate upon a spindle by the act of cocking the hammer." His improvement on this plan, which consisted in using a rotating cylinder containing several chambers, all of which discharge through one barrel, was patented in England in 1835, and in this country in 1836.

The rifle (*A B C*, Fig. 4292, page 1929) has a steel barrel with seven flat angular grooves. The lock-frame is provided with a bridge *a* above the barrel, and the stock is in two parts *b b'*, called respectively the butt and tip. It is adapted to receive a bayonet. The tip in some cases is dispensed with.

The rod by which the cylinder is secured to the barrel has a ratcheted disk *c'* near its rear end, which is engaged in the act of cocking, by a hook connected with the tumbler, rotating the cylinder and bringing each chamber successively in line with the barrel.

Fig. 4325 shows Maynard's rifle. It may, at the option of the user, be provided with two rifle-barrels of different calibers and a shot-barrel, one of which may be substituted for the other by simply releasing the pin *a* which, with the fixed pin *b*, connects the barrel with the stock and firing mechanism, removing the first barrel and securing the second by placing the pin *b* in the hook and reinserting the pin *a* after bringing the holes in the flanges, one of which is seen at *c*, and the arm *d* (shown in dotted lines) into line. These operations take but very few moments to perform.

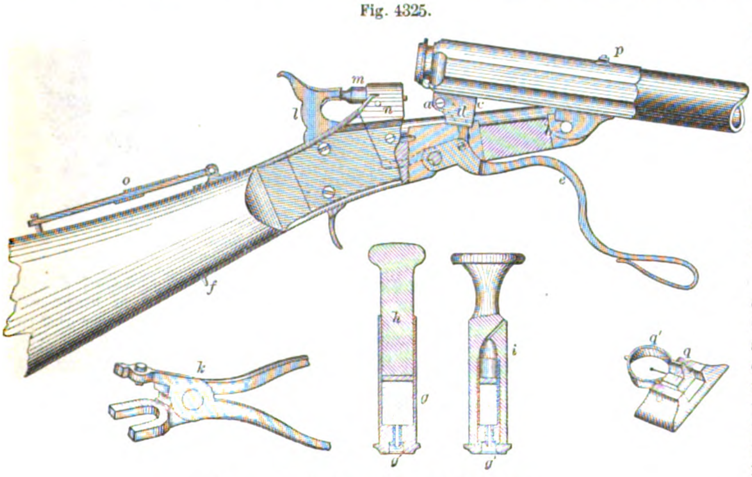
The rear end of the barrel is thrown up for this purpose, and also for loading, by turning forward the lever *e*, which also serves as the trigger-guard. When this is restored to its normal position, it is held by the pin *f* near the small of the stock, and the movement, by means of the arm *d*, draws the breech down into a groove in the metallic part of the stock, where it is in position for firing. Either the forward or backward movement of the trigger-guard *e* places the lock at half-cock, obviating the danger of premature discharge.

The Maynard rifle was perhaps the first in which a metallic cartridge was employed. The report of Major Bell to Colonel Craig, Chief of Ordnance, United States Army, May 16, 1856, describes the firing of Dr. E. Maynard's rifle, charged with a metallic cylindrical water-proof cartridge, and dwells upon the important fact of the coincidence of the axes of the ball and the barrel, obtained by the symmetrical setting of the ball in the metallic shell. The bullet was held in the shell by its exact fit, and without choking the shell upon it. The Maynard coil-primer was then used with it; the nipple and percussion-cap were substituted in 1864; the plunger exploder, in 1873; the Berdan primer, in 1874.

The cartridge cases *g* are of sheet-metal, sufficiently thick to permit their being used an indefinite number of times, and have a thick base, perforated to allow the passage of fire from the primer, which is a cap placed on a nipple slightly recessed within the cavity *g'* of the base. The charge of powder is placed within the case, and with the wad, if one be used, is rammed by the short rod *h*, which also serves for ramming the wad over shot when these are employed.

If ball be used, it is pushed into the case by means of the loader *i*, which has a cylindrical cavity terminating in a hollow conoid fitting the point of the ball and keeping it in truly axial position in the case. The flange at the base of the cartridge enables it to be readily withdrawn from the loader and from the barrel after firing. The device *k* is used for pressing the primer, a shallow, flanged cap, upon the nipple. The cartridge, having been loaded as described, is pushed into the rear of the barrel, which is then depressed by throwing backward the trigger-guard *e* until its loop rests against the stock, the pin *f* entering a hole in the guard. The hammer *l* is drawn back to full cock, and on pulling the trigger the main-spring throws the tumbler forward, causing the hammer to strike the firing-pin *m*, which is projected forward within an aperture in the breech-block *n*, and explodes the primer. The breech-block, backed by the stock in rear of it, sustains the force of the recoil.

Fig. 4325.



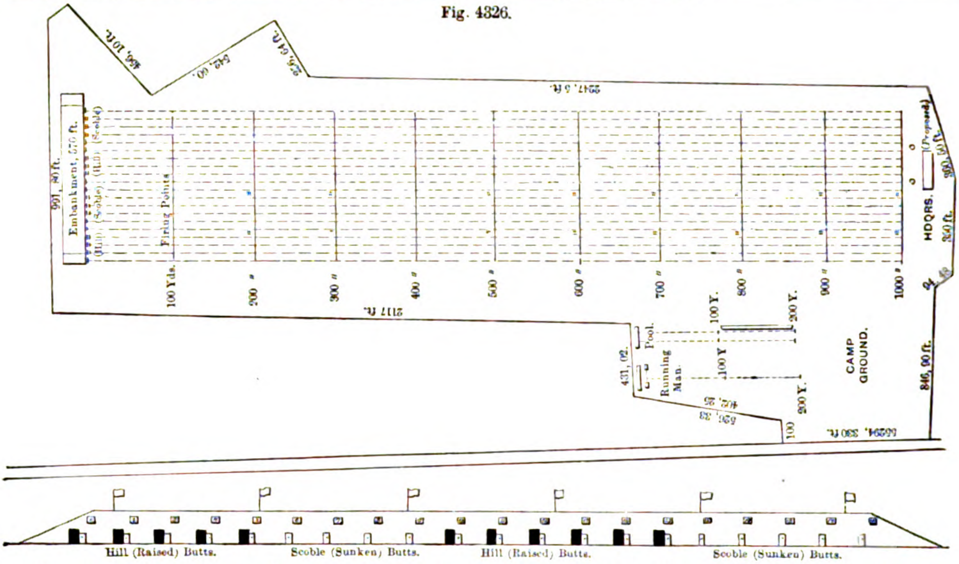
Maynard's Combined Rifle and Shot-Gun.

The rear sight *o*, pivoted on the small of the stock, is a slide-sight, adapted for long ranges, and is turned down when not in use. The block-sight *p* is used for short distances. The front sight *q* is compound, consisting of an ordinary sight and a globe-sight *q'* turning on a common pivot in a slotted base fixed near the muzzle of the barrel.

The barrel being readily detachable, enables the whole arm to be packed within a space not exceeding the length of the barrel, usually 26 inches.

Fig. 4326 shows a plan of the rifle-grounds at Creedmoor, Long Island, and Fig. 4327 is a sketch of the group of marksmen. The figures on the plan give the distances of the different ranges, and the lower view shows the mode of shooting, which was singular enough with

Fig. 4326.



Upper Figure: Plan. Lower Figure: Front Elevation of Embankment, showing Targets as seen from Firing-Points.

Rifle-Range, Creedmoor, Long Island.

some of the party. One man has the toe of his boot for a rest, another his crossed legs.

The shooting at the contest between the American and the Irish teams was the best on record.

The possible individual score was	180
The possible six-team score was (6 × 180)	1,080
The best individual score (Fulton, American) was	168
The American team score was	934
The Irish team score was	931

The best previous shooting at Wimbledon was 1,204 out of a possible 1,440.

Rifled cannon were first successfully employed during the Franco-Austrian war in Italy, 1859. The Lancaster gun had, however, been tried to some extent during the Crimean war.

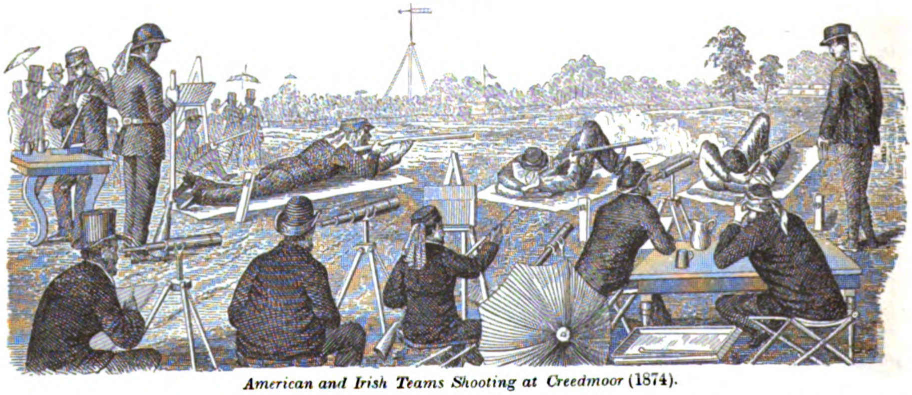
They may be divided into four classes:—

1. Guns in which the projectile is made entirely of hard metal, and of section corresponding to and fitting the bore, but having a small windage; such as the Lancaster and Whitworth, just described.

2. Muzzle-loading guns with balls having studs or ribs fitting the grooves; as the Armstrong and others.

3. Muzzle-loading guns having projectiles with expansible cups or envelopes of soft metal, which are forced into the grooves in the act of firing, so as to prevent windage; as Parrott's, Blakeley's, etc.

Fig. 4327



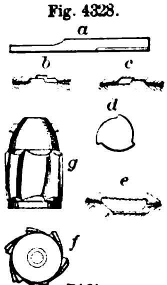
American and Irish Teams Shooting at Creedmoor (1874).

4. Breech-loading guns. In these the projectile has a soft metal coating, which is forced into the grooves in the same way as the leaden bullets of small-arms; *e. g.* the Prussian and Armstrong's.

The grooves of the Armstrong muzzle-loader are made deeper on one side than on the other, as shown in Fig. 4328, *a*; the deeper part is of uniform depth and connected with the shallower part by an incline. The studs on the shot are only half the width of the grooves, and of hight sufficient to allow the shot to enter the bore and pass down freely to its seat, as shown at *b*. When driven forward by the force of the discharge, the studs come in contact with the incline, and are *shunted* over into the shallower part of the groove, against which they bear firmly, causing the shot to leave the bore in a line concentric with its axis, as shown at *c*.

In the Scott gun this is effected by making the

Fig. 4328.



Rifling and Rifle Projectiles.

grooves of gradually decreasing depth from one side to the other (*d*).

The French system, of which the Woolwich is a modification, is shown at *e*.

The Austrian (*f*) in principle resembles this, the grooves being a series of spiral triangles; the projectile (*g*) has corresponding soft-metal ribs, which readily pass down the bore along the deeper sides of the grooves and are shunted over to the shallower sides when discharged.

See also SHELL; BULLET; and specific indexes under ORDNANCE and PROJECTILES.

2. (*Husbandry.*) A strop with a surface of emery for whetting scythes, etc.

Ri'fle-pit. (*Fortification.*) A pit or trench which, together with the excavated earth, forms a defense for a rifleman in an advanced position, where he may pick off the enemy's gunners or defend his own line.

The rifle-pits in the Crimea were holes 4 feet long and 3 feet deep, the parapet of earth crowned by 3 sand-bags having a loophole through which to fire.

The rifle-pits in the United States service were trenches and parapets for systematic advanced defense or attack, and holes scraped in the ground, occupied by sharpshooters who fought *each on his own hook*.

Rig. (*Nautical.*) *a.* The style of masting and sails of a vessel, as *square*, *fore-and-aft*, *schooner*, *lugger* rig, etc.

b. To prepare a *purchase* for use.

c. To furnish the masts and yards with rigging.

d. To thrust out a boom or spar.

Rig'ger. (*Machinery.*) A band-wheel having a slightly curved rim. Fast and loose pulleys are so called in English works on machinery.

Rig'ging. (*Nautical.*) The system of cordage on board a vessel. See MAST; ROPE.

1. The *standing rigging* includes: —

a. The *pendants*; strong ropes over the lower-mast heads, and having thimbles for attaching tackle.

b. The *shrouds*; supporting the masts laterally, and having *ratlines* by which they are ascended.

c. The *stays*; supporting the masts forward.

d. The *back stays*; passing from the mast-heads to the channels abaft the masts.

e. *Ratlines*; the steps of the shrouds.

f. *Slings*; by which the centers of the yards are secured to the masts.

g. *Trusses* and *parrals*; for connecting the yards to the masts.

h. *Gammoning*; the lashing chain which secures the heel of the bowsprit.

i. *Martingales*; the stays of the jibboom and flying jibboom.

j. *Guys*; lateral jibboom stays.

k. *Slings*; by which the yards are suspended. Also, —

Heel-chains.	*Ridge-ropes.*
Crupper-chains.	*Horses.*
Man-ropes.	*Stirrups.*
Foot-ropes.	*Flemish-horses*, etc., etc.

See under the respective heads.

2. The *running rigging* comprises: —

a. The *halyards*; by which a yard or *gaff* is raised.

b. The *lifts*; for raising and lowering the ends of the yards.

c. The *braces*; for trimming the yards fore and aft.

d. The *sheets*; by which the lower corners of a sail are extended.

e. The *clew-garnets* for the courses, and *clew-lines* for the upper sails; by which the *clews* of the sail are drawn up to the yard in the process of furling.

f. The *tacks*; ropes to confine the foremost lower corners of *courses* and *stay*-sails.

g. *Bowlines*; attached to the edges of a square sail, and hauled forward on the weather side, when the ship is on a wind.

h. *Buntlines*; ropes attached to the *foot* of a square sail to raise it when taking it in.

i. *Downhauls*; by which fore-and-aft sails are drawn down.

k. *Brails*; ropes used to gather a fore-and-aft sail up to its gaff, for furling.

l. *Reef-tackles*; by which the *earings* at the ends of the *reef-bands* are drawn up to the yard in reefing.

m. *Signal-halyards*; by which flags are raised to the mast-head or peak.

n. *Outhauls*; ropes used for extending the clews of a boom sail.

o. *Inhauls*; for rigging in the jibboom, studding-sail booms, etc.

p. *Leechlines*; lines attached to the leech-ropes of sails and passing up to blocks on the yards to haul the *leeches* by.

q. *Slablines*; lines by which the feet of the mainsails or foresails are hauled up.

r. *Spans*; ropes connected by both ends to the object, the purchase being hooked to the bight.

s. *Tripping lines*; used to unring the lower topgallant yard-arm when striking it or lowering it on deck.

t. *Tyes*; ropes made fast to yards and passing through the masts. By tackle attached to the other ends of the tyes the yards are hoisted.

u. *Vangs*; to steady laterally the peak of a *gaff*.

Right-hand Rope. One laid up and twisted *with the sun*. Left-hand rope is called *water-laid*.

Right-line Pen. A drawing-pen.

Ri-li-e'vo; Re-lief'. The prominence of a sculptured figure beyond the plane surface to which it is attached.

Alto-rilievo, or *high relief*, is the most prominent, the figure being sometimes only attached at a few points to the plane surface.

Mezzo-rilievo, *demi* or *half relief*, has a prominence of about one half the thickness of the figure.

Basso-rilievo, *bass-relief* or *low relief*, has but slight projection, as in the ornaments of friezes, medals, coins, etc. See the above.

The rilievo work of the ancient Egyptian sculptors did not project beyond the general line of the face, but was executed in a sunken panel, so that the highest relief was only flush.

Rim. A marginal portion of an object, generally circular.

1. (*Vehicle.*) *a.* The circular wooden portion forming the periphery of a wheel. It consists of bent portions or of sawed pieces called *fellies*. It is encircled by the *tire*, and is connected by *spokes* to the *hub* or *nave*.

b. The peripheral portion of a car-wheel attached by *spokes* or *web* to the *boss* or *nave*.

2. (*Nautical.*) *a.* The extreme edge of the top.

b. The circular, notched plate of a capstan or windlass into which the pawls drop.

3. The elliptical bows of spectacles in which the glasses are set.

4. The projecting margin of a kettle by which it is suspended in a furnace.

Rim'base. 1. (*Ordnance.*) A short cylinder at the junction of a *trunnion* with the gun. It is an enlargement or shoulder to the trunnion which forms the journal to the piece in elevating or depressing. See CANNON.

2. (*Small-Arms.*) The shoulder on the stock of a musket against which the breech of the barrel rests.

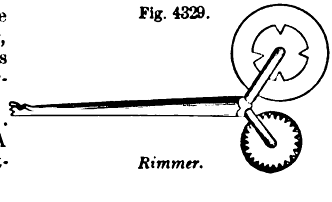
Rime. The *rung* or *round* forming the step of a ladder. A specific tool for making it is known as a *rimer*. The best tools are the drawing-knife and spokeshave to round up the *rived* timber.

Rim'er. 1. A boring implement for enlarging holes. See REAMER.

2. (*Fortification.*) A palisade.

Rim-lock. A lock having an exterior metallic case which projects from the face of the door, differing thus from a *mortise-lock*.

Fig. 4329.



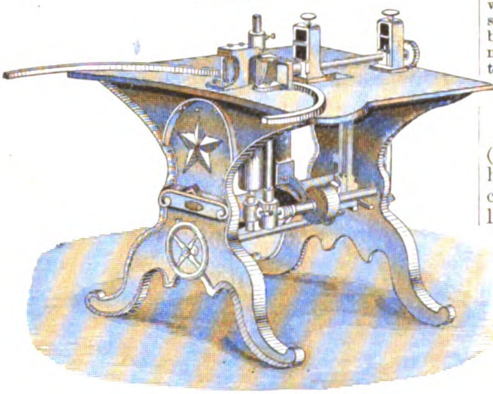
Rimmer.

Rim'mer. (*Domestic.*) A device for cut-

ting and ornamenting the edges of pies, etc. The example has a handle provided at one end with a rotary cutter secured to an irregular or ornamental roller and corrugated wheel, and at the other end with a butter-cutter or print.

Rim-plan'ing Ma-chine'. (*Wood-working.*) A machine for planing simultaneously one curved and one flat surface of a wheel-felly. The felly is carried circularly round by vertical feed-rolls operated by a screw and worm-wheel assisted by a horizontal feed-roll, which also holds the work down to the table. Vertical and horizontal knives, adjustable as to

Fig. 4330.

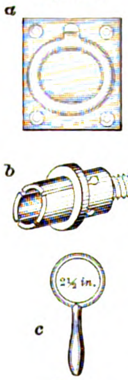


Rim-Planing Machine.

depth of cut, take off a shaving of the desired thickness from the periphery and side as the work passes between them.

Ring. 1. A hoop of metal used as a means of attachment, of the nature of a link, as in the *ring-bolt*, *lap-ring*, the ring on a neck-yoke, etc. In other cases, as a means of assembling, as the *key-ring*, *split-ring*. Other applications are common and obvious.

Fig. 4331.



Rings.

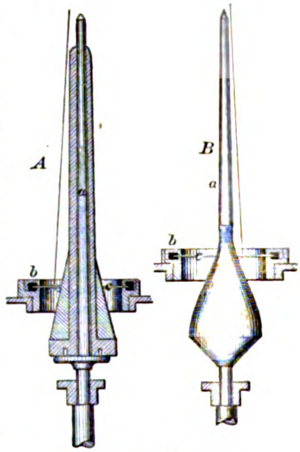
2. A kind of handle for drawers, etc. It is hinged above, and falls into a groove when not in use, so as to be flush with the surface. *a*, Fig. 4331.

3. (*Nautical.*) The appendage by which the cable is attached to the anchor by means of the shackle on the end of the chain-cable, called the anchor-shackle. See ANCHOR.

Ring and Trav'el-er Spin'-ning-frame. Jenks's *ring*-spinner is a modern machine. It is employed, like the throstle, for spinning warp-yarns; it makes a cop resembling that made by the mule, and, like the latter, its bobbin is adapted for the shuttle. The spindles are arranged vertically in the frame, and project through apertures in a horizontal bar. A flanged ridge around each aperture forms a *ring*, and affords a track for a little steel hoop called a *traveler*, which is sprung over the *ring*. The traveler guides the thread on to the spool. As the spindles revolve, the thread passing through the *traveler* revolves it rapidly, and the horizontal bar ascending and descending alternately winds the yarn regularly upon the spools.

Potter's ring and traveler (Figs. 4332, 4333) is designed for spinning all staples, its use not being confined exclusively to cotton. *A* is a spindle with one head bobbin; *B*, a cop-spindle; *a* represents the revolving-spindle; *b* the ring, which is hollowed out so as to form an annular groove. The traveler *c* is a straight or curved bar extending across the central opening of the ring, and while revolving around the spindle is balanced upon the yarn, which is kept at a uniform angle with the spindle, whether winding upon the bare spindle or upon a full bobbin, consequently maintaining a uniform tension and lessening the liability to breakage.

Fig. 4332. Fig. 4333.



Ring and Traveler.

Ring-bit. (*Menage.*) A bit having a ring-cheek, whether loose or otherwise.

Ring-bolt. (*Nautical.*) A ring passing through an eye in the end of a bolt which is secured to the deck or side of a vessel or on a wharf. It is used for attachment of a rope or tackle. On each side of a port it is used for hooking the train-tackles by which the gun is maneuvered.

Ring-chuck. A hollow chuck (*b*, Fig. 4331) whose grasping end is capable of being contracted by a ring, so as to hold firmly the object to be turned. The screw end fits the mandrel of the lathe-head.

Ring-dogs. Two dogs attached to a ring for hauling timber. See DOG.

Ring'er. 1. (*Mining.*) A crow-bar.

2. A chiming or bell-ringing apparatus. See Fig. 648, page 271.

Ring-gage. 1. (*Road-making.*) A ring (*c*, Fig. 4331) 2½ inches wide in the aperture, used for determining the size of broken stone under the Macadam system of road-making. Telford and Macadam, the English engineers who reduced the making of roads to a system, adopted the size of 2½ inches extreme limit as the best for the purpose.

2. (*Jewelry.*) A conical piece of wood or a tapering metallic slip, having marked upon it a series of sizes of rings, according to an established gage, or actual parts of an inch in diameter.

3. (*Ordnance.*) A circular steel gage used in inspecting shot and shells. They are made of two sizes for each caliber, the larger being a trifle more and the smaller a trifle less in diameter than the true caliber of the projectile. All shot received must pass through the larger gage, but are rejected if they pass through the smaller.

Ring'ing-en'gine. A simple form of *pile-driver* in which a ram weighing about 800 pounds and moving between timber guides is attached to one end of a rope passing over a pulley. The other end of the rope branches out into a number of ropes, each held by one man, in the proportion of one man to each 40 pounds of weight in the *ram*. They lift the ram about three or four feet, and let go on a given signal. The number of blows is from 4,000 to 5,000 per day. See also PILE-DRIVER, Figs. 2717, 2718, pages 1702, 1703; and specific index under HYDRAULIC ENGINEERING.

Ring-lock. A kind of puzzle or letter-lock in which the bolt is surrounded by a number of mova-

ble rings, having grooves which must be ranged in a straight line with one another before the bolts can be drawn.

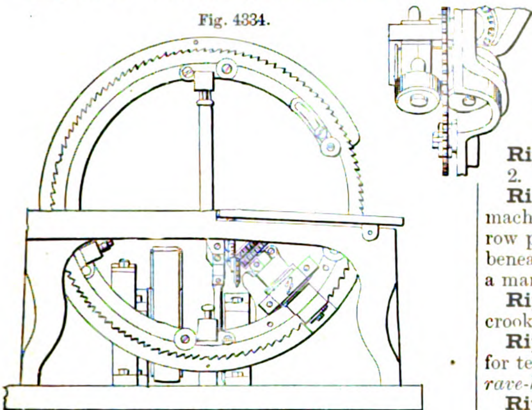
Ring-mi-crom'e-ter. A metallic ring fixed in the field of a telescope, and used to determine differences of declination between stars from the differences of time occupied by them in traversing different chords, either of the inner or outer periphery of the ring. A circular micrometer.

Ring-rope. (*Nautical.*) A rope secured to a ring-bolt in the deck to secure the cable or a purchase, or to check the cable in veering.

Ring-sail. (*Nautical.*) A small, light sail set on a mast on the *taffrail.*

Ring-saw. One having an annular web. The

Fig. 4334.



Ring-Saw.

example shows one driven by friction-rollers and directed by guide-rollers.

Ring-spin'ner. (*Spinning.*) See RING AND TRAVELER SPINNER.

Ring-tail. (*Nautical.*) An additional sail set abaft the spanker or driver, to extend its area in light winds.

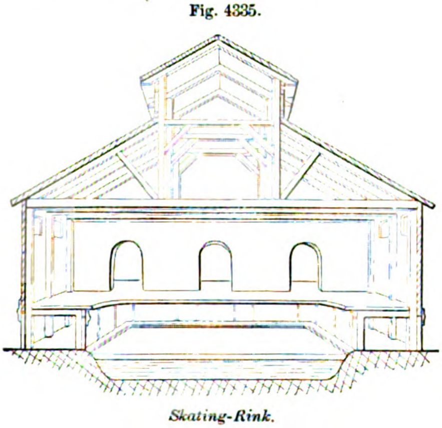
Ring-tail Boom. (*Nautical.*) A spar to rig out on the spanker-boom to set the ring-tail.

Ring-tum'bler. (*Locksmithing.*) An annular-shaped tumbler in a lock.

Ring-wall. (*Metallurgy.*) The inner lining of a furnace.

Rink. A skating-pond. That shown is under cover, and has doors in the foundation, which allow access of external air when required.

Fig. 4335.

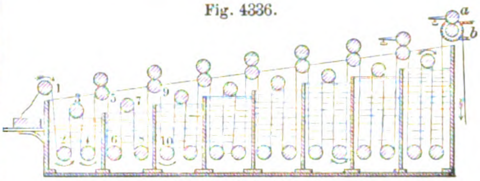


Skating-Rink.

Rins'ing-ma-chine'. (*Cotton-manufacture.*) An apparatus for removing impurities or surplus color from cotton cloth or prints.

The stuff is drawn alternately over and under a series of rollers 1, 2, 3, 4, etc., through tanks *a b c d*, and finally passes be-

Fig. 4336.



Rinsing-Machine.

tween the rollers *a b*, by which it is partially dried. The tanks successively increase in hight from the left to the right hand side of the apparatus, the water overflowing from one into the other, so that a current is caused to flow in an opposite direction to that in which the cloth is moving, the impurities being gradually removed during its progress.

Rip'per. 1. A tool for edging slates for roofing. 2. A tool for ripping seams of garments.

Rip'ping-bed. (*Marble-working.*) A machine for ripping a slab of marble into narrow pieces by passing it on a traversing bed beneath a gang of circular saws arranged on a mandrel. A *stone-saw.*

Fig. 4337.

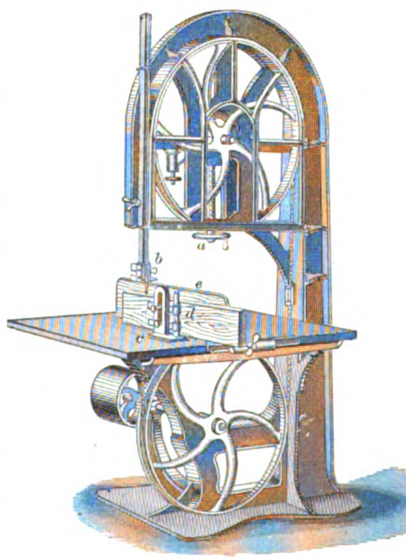
Ripper.

Rip'ping-chis'el. (*Wood-working.*) A crooked chisel for cleaning out mortises.

Rip'ping-i'ron. (*Nautical.*) A hook for tearing old oakum out of the seams. A *rave-hook.*

Rip'ping-saw. A saw for cutting wood lengthwise of the grain. Fig. 4338 illustrates a band-saw adapted for this purpose. The upper pulley is journaled in yielding bearings, adjustable in hight by the screw *a*, to impart the required tension. In front of the saw is a hinged gate, to prevent injury to the workman in case of slipping or breakage. The guide *b* is adjustable to suit different thicknesses of timber. The ripping-gage *c d* is

Fig. 4338.



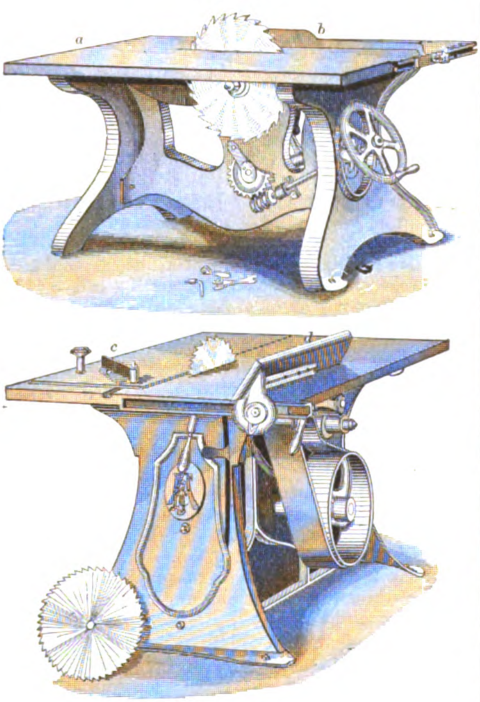
Ripping-Saw.

screwed to the table, and, by means of a thumb-nut, is adjusted to cut square or beveling, and the work is held firmly against the fence *e* by springs adjustable by thumb-screws.

Circular rip-saws differ principally in regard to the modes of hanging and the provisions for feeding and guiding the timber. In *a*, Fig. 4339, the guiding is effected by the fence *b*, which is moved parallel to the saw and held by a parallel-motion device at the end of the table.

The lower figure has a corresponding fence *c*, to be

Fig. 4339.



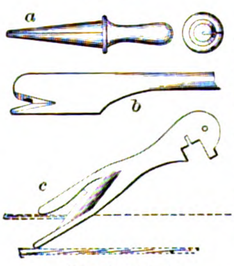
Ripping-Saws.

used for ripping, and a guide *e*, which can be moved transversely of the table, and is pivoted, so that the timber may be presented at any angle to the saw, which can thus be used for cross cutting.

d is a fence, the face of which is adjustable to any angle with the bed.

Rip'ping-tool. One for following a seam and cutting stitches without slitting the fabric.

Fig. 4340.



Ripping-Tools.

In the examples: —

a is a tool, like a bodkin, with a longitudinal radial blade. The cone spreads the seam open, and the stitches are drawn across the blade.

b is a thrusting tool, whose pointed portion expands the seam, the threads being cut by the sharp edge or angle.

c is somewhat similar to the last.

Rip'ple. An instrument (*a*) with teeth like a comb, through which flax is drawn to remove the capsules and seed therefrom, when the lint of the plant is to be used.

It is a very ancient instrument, having been used in Egypt in the time of the Pharaohs for removing the seed from the *dhura*, a variety of imphee or sorghum which was then cultivated for bread grain. The tombs have paintings *c* representing the rippling of *dhura*.

Fig. 4341.

Ripple and Rippling-Comb.

It was also used in the time of Pliny, for shelling the grain out of the ears of wheat; one mode of thrashing.

The implement (*b*) is placed on a stool, and the seed caught by a cloth spread beneath. The teeth are 18 inches long, ½ inch square at bottom, and tapering at the point.

A handful of flax is grasped by the butts, is spread like a fan, and, being thrown upon the comb, is drawn between the teeth, removing the seed.

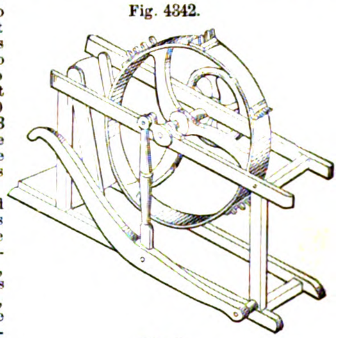
The stalks are then carried to the steeping-pool or watercourse, where it is *retted* or *rotted*.

The ripple is yet used in Japan for thrashing out grain, as it was in Egypt in the time of the Pharaohs.

The *dhura* was cultivated in the Nile country for a time that history telleth not to the contrary, forming the food of the poorest class. It yields a produce of about 240 for one. Hamilton states, in his *Ægyptiaca*, that the thrashed grain is only worth 3*s*. 9*d*. the *ardeb*, which is scarcely 6 cents per bushel. The *dhura* constitutes the chief subsistence of the peasantry in Upper Egypt. It multiplies itself even more quickly than rice.

To the great abundance of food is owing the great increase in population. Diodorus Siculus, who traveled in Egypt nineteen centuries since, states that to bring up a child to maturity did not cost more than 20 drachmas, about 3 dollars. It must be recollected that the value of money has decreased.

Fig. 4342.



Ripple.

The ripple is used in the United States for stripping the seed from broom-corn. In Fig. 4342, the treadle actuates the spiked wheel, which cleans the seed from the broom-corn when it is placed in the chute.

Rip-rap. (*Masonry.*) A foundation of loose stones. The artificial island in Chesapeake Bay, which is thus formed, is named the Rip-raps, and forms one of the defenses of Hampton Roads. Fort Sumter, Charleston Harbor, and Plymouth Breakwater, England, are founded on rip-raps.

Rip-saw. A saw whose teeth and mode of filing adapt it specially for *ripping* boards, that is, sawing them *with* the grain. In contradistinction to *cross-cut*. It has usually eight teeth to three inches. A half-ripper has teeth of modified form, and has three teeth to the inch. See RIPPING-SAW.

Rise. 1. (*Architecture.*) The *versed-sine*, or elevation of an arch above the *springing-line*.

2. (*Carpentry.*) The hight of a step in a flight of stairs; the width of a step is the *tread*.

3. (*Mining.*) A perpendicular *shaft* or *winze* excavated from below upward.

Ris'er. 1. (*Carpentry.*) The upright board of a step. The flat board is the *tread*.

2. (*Mining.*) A shaft excavated upward.

3. (*Founding.*) An opening through a mold, into which metal rises as the mold fills. A *head.*

Ris'ing. 1. (*Nautical.*) A narrow strake in a boat, beneath the thwarts.

2. (*Mining.*) A shaft worked from below, upward. The opposite of *sinking.*

Ris'ing-an'vil. (*Sheet-metal Working.*) A double beak-iron.

Ris'ing-arch. A rampart arch.

Ris'ing-floors. (*Shipbuilding.*) The floor-timbers which rise fore and aft from the plane of the midship floor.

Ris'ing-hinge. One so constructed as to elevate the foot of an opening door, to avoid the carpet.

Ris'ing-line. (*Shipbuilding.*) A curved line on the drafts of a ship, marking the hight of the floor-timbers throughout the length, and thereby fixing the sharpness and flatness of a vessel's bottom.

Ris'ing-main. The vertical pipe from a pump in a well to the surface of the ground.

Ris'ing-rod. (*Steam-engine.*) A rod in the Cornish steam-engine which rises as the cataract piston descends, by means of levers; it then lifts catches by which the sectors are released, and the weights are enabled to open or shut the equilibrium or exhaust valves.

Ris'ings. (*Shipbuilding.*) Thick planks supporting the timbers of the decks.

Ris'ing-square. (*Shipbuilding.*) A square upon which is marked the hight of the rising line above the keel.

Ris'ing-wood. (*Shipbuilding.*) A timber worked into the seat of the floor and into the keel to steady the floor-timber.

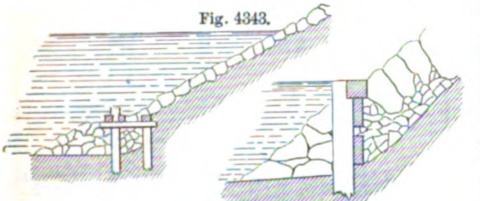
Riv'er-wall. (*Hydraulic Engineering.*) A wall made to confine a river within definite bounds, either (1) to prevent denudation or erosion of the banks; (2) to prevent overflow of the land adjacent; or (3) to concentrate the force of the stream within a smaller sectional area for the purpose of deepening a navigable channel.

The considerations adduced in reference to certain maritime structures (see SEA-WALL; JETTY; QUAY; GROIN; BREAKWATER) do not all apply to river-walls, as the latter are not exposed to the dashing action of the waves from the open sea, nor usually to so heavy a pressure of earth, which is alternately wet and dry twice a day, as in structures on tide-water.

The construction of the dikes of Holland furnishes many valuable suggestions for fluviatile erections, for, in these works, every material has been brought into use which seems to have any importance or usefulness.

Masonry, rubble, concrete, puddle, piles, boarding, fascines, stakes, earth, osiers, and reeds in bundles and growing, each is introduced to perform its part in the work of forming a barrier against the adjacent sea and the interior network of rivers and canals.

Fig. 4343.



River-Walls.

As in the cases cited, the artificial bank may consist of a rubble facing with a foot piling to support it, and having a slope of not less than 3 base to 2 vertical hight, the latter depending upon the exposure, and the rate of the current.

The Piedmontese engineers use prisms of concrete, forming a slope of 45°.

The banks of the Medway, England, are locally protected by a bed of concrete.

Fascines in crosswise layers alternating with gravel, clay, sand, and shingle are used in Holland. See FASCINE.

On the banks of the Rhine, panniers and gabions filled with gravel are employed.

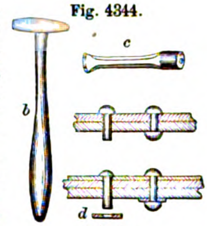
Riv'et. (*Machinery.*) A short bolt with a flat or rose head, employed for uniting two plates or thin pieces of material together. The stub end is swaged to prevent its withdrawal. When used for joining pieces of leather, as in making belting, an annular disk, termed a *burr*, is placed over this end previous to swaging, in order to give a greater bearing.

Rivets are cut from round metal rods, and formed by special machinery.

The *rivet* was the main dependence of the armorer for fastening plates of armor. In Homer's time *welding* and *soldering* were apparently unknown, and plates were attached by mechanical means; rivets, pins, nails, cramps, and dovetails.

In riveting iron plates together, as in boilers, tanks, etc., the rivet is made red-hot, and while a sledge is held against the head, the end is swaged down by striking directly with a riveting-hammer, or a species of die called a snap-head is interposed. In riveting together wooden surfaces, they may be lined with metallic plate, or washers be placed under the head and the swaged burr, to prevent the indentation of the wood. Machines are also employed for riveting. (See RIVETING-MACHINE.)

Fig. 4344.



Rivets.

Fig. 4345.

Rivet.

In riveting the plates composing the skin of iron ships, it is necessary that the outer end of the rivet should be flush with the plate. A countersink is, accordingly, formed in this side. The operation of riveting is performed by three men and a boy. The latter brings it from the furnace with a pair of tongs and passes it to the holder up, who receives it in a short pair of tongs and inserts it into the rivet-hole from the inside. He then presses against it with a hammer or with a tool called a *dolly*, having its end indented to receive the head of the rivet, while the two men on the outside hammer the other end down so as to fill the countersink.

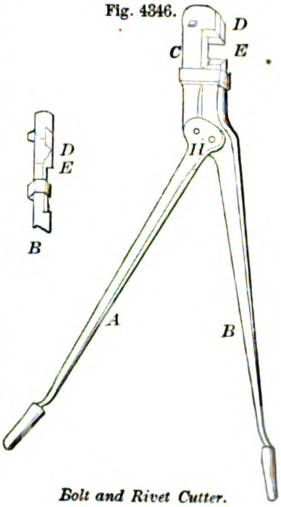
The plates may be put on with either *lap* or *flush* joints, their ends in the latter case butting. The first may be effected by a single row of rivets, the latter requires two. Double riveting requires two rows of rivets when the plates lap, or four for flush jointing. It has more than two thirds of the strength of the original plates, while single riveting affords somewhat over half of said strength.

Riv'et-cut'ter. A jaw tool for cutting off flush the stub ends of rivets or bolts. In the example, the handle *A H* is pivoted to the handle *B* and piece *C*, so that the jaws *D E* are brought together as the handles are compressed.

Riv'et-hearth. A shallow, round fuel-tray, mounted on three legs, and having a circular bellows beneath it for blowing the fire.

It is set up near the place where the rivets are to be driven. One of them is required for every two or three gangs of riveters. The boys who carry the rivets operate the bellows.

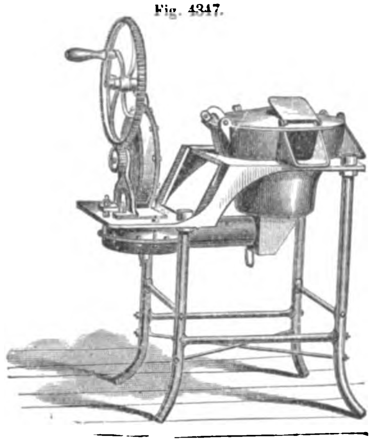
Fig. 4346.



Bolt and Rivet Cutter.

The hearth is formed of a slight iron frame and iron plates; on a separate frame is a small, round bellows, so arranged as to be operated by each mo-

Fig. 4347.

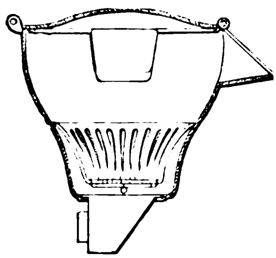


"*Keystone*" *Riveting-Forge.*

tion of the hand, up or down. See RIVETING-TOOLS.

Riv'et-ing-forge. The portable riveting-forge (Fig. 4347) has a pot rotatable by gearing and having three doors, so as to employ three operatives; it contains a grate-like basket, which allows the blast from the tuyere to pass through. At the bottom of the basket is a grate and a comb-raker, operated from the outside. Beneath the grate is the tuyere box. A fan is provided for creating a blast.

Fig. 4348.



Riveting-Pot.

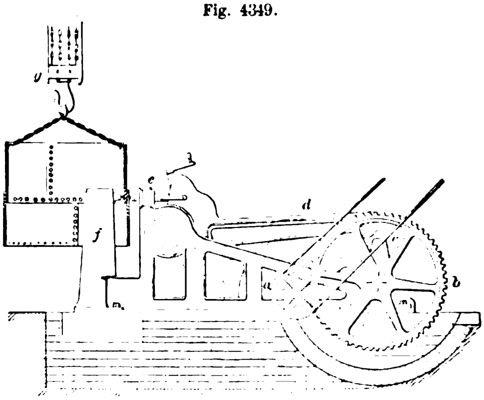
Riv'et-ing-ham'mer. A hammer for swaging a rivet when in position. It has usually a long, flat-faced head, and a narrow peen. *b*, Fig. 4344.

Riv'et-ing-ma-chine'. (*Boiler-making.*) A machine in which the operation of riveting boiler or other metallic plates is performed by steam-power. Its general principle is that of the punching-machine. The first application of steam to this purpose is due to Sir William Fairbairn, of Manchester, England. He employed a movable horizontal die, in conjunction with a fixed die at the head of an iron pillar; the work to be riveted being inserted between the two. The same general construction has been adopted in subsequent machines. Sir William Fairbairn states that the machine was contrived when he had a large number of orders on hand for his double-flued boiler and the men struck. "In this dilemma I was driven to the necessity of supplying the place of the riveters by a passive and unerring workman, which, from that day to this, has never complained, and did as much work in one day as was formerly accomplished by twelve of our best riveters and assistants in the same time. I desired the foreman to reverse the action of the punching-machine, and with proper dies to rivet the plates instead of punching them. In six weeks from that date we had the riveting-machines at work, making tighter joints and executing the work with greater perfection than could possibly be done by the hammer."

Fairbairn introduced many improvements in machinery employed for various purposes, which have been universally adopted. His attention having been drawn to the advantage of iron as a material for building ships, in 1836 he built and successfully launched a small iron vessel. This was one of the very first of its class built in England. In after life he constructed many large vessels of the same material at his shops in Millwall. He was one of the very first to plan and construct buildings of iron. He was chosen to assist Stephenson in the construction of the great tubular iron bridge over the Menai Strait, for the Chester and Holyhead Railway. He was chiefly instrumental in the introduction into general use of wrought-iron plate girders in building operations, as well as in railway engineering. His principal works are on "The History and Manufacture of Iron," "Mills and Mill-Work," and "Iron Shipbuilding." He died August 18, 1874.

The machine illustrated in Fig. 4349 is set in motion by a band on the pulley *a*; on the axis of the latter is a pinion gearing into a large spur-wheel *b*, on whose axis is a cam *c* operating the riveting-lever *d*, the face of the cam being steeled and the

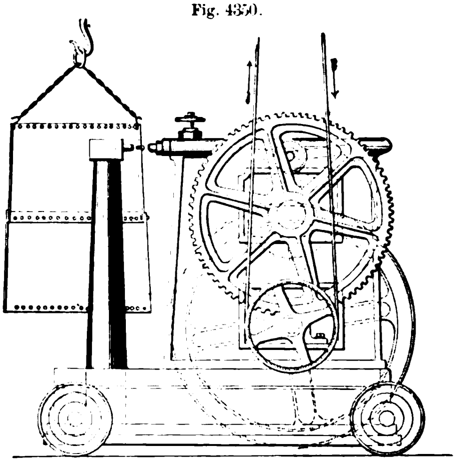
Fig. 4349.



Riveting-Machine.

end of the lever having a roller to diminish the friction. The riveting-lever has a fulcrum in the frame, and acts by its face upon the riveting-tool *e* when punching and by a link connec-

Fig. 4350.



Riveting-Machine.

tion with the tool when retracting, the tool sliding in a socket fixed in the side frames.

The face of the riveting-tool has a depression which receives the end of the rivet and swages it to shape.

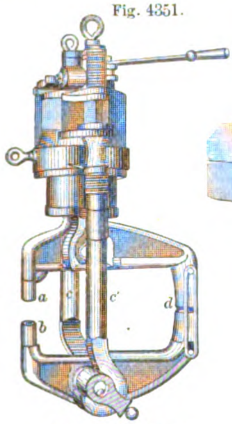
The anvil-post *f* rises from the foundation, and has a riveting-block of the shape of a frustum of a cone. The sections of boiler are lowered from above, by means of tackle *g*, the point at which the rivet is to be placed being adjusted between the punch and the anvil-block. The rivet is placed in the punched holes, the band slipped on to the fast pulley, and the upward motion of the cam raises the lever and swages the rivet.

Fig. 4350 is a portable machine on the same plan. Not being intended for such heavy work, its frame is less massive than that of the foregoing, and the construction and arrangement of its details are slightly different.

In Tweddel's machine (Fig. 4351), the distance between the punch *a* and anvil *b* is regulated, according to the thickness of the plate, etc., by screws *c c′* and links *d*. The whole apparatus is mounted on a truck, and the pressure applied by a hydraulic accumulator operated by a portable engine.

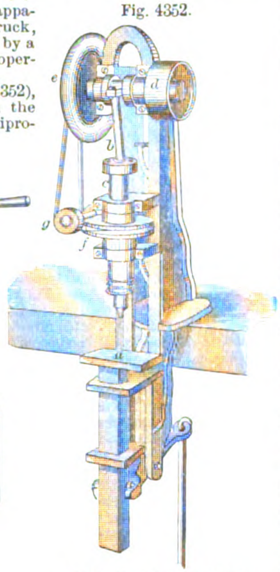
In Adt's machine (Fig. 4352), the work is supported on the table *a*; the punch is reciprocated by a pitman *b*, having a universal joint connection with the spindle *c*, and actuated by an eccentric on the pulley-shaft *d*; the punch spindle is at the same time revolved by a belt on the shaft of the fly-wheel *e*, imparting motion to the pulley *f* through two small change pulleys, one of which is seen at *g*.

Fig. 4351.



Riveting-Machine.

Fig. 4352.

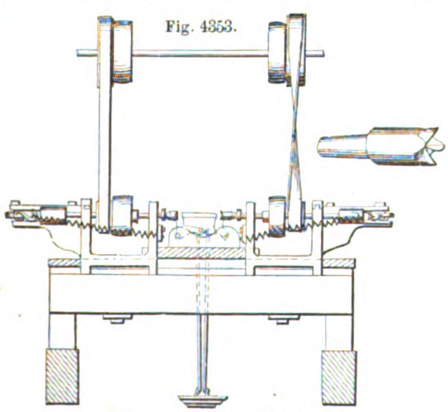


Adt's Riveting-Machine.

In another machine intended for heading caster and hinge pintles, etc., the spring-hammers strike the opposite ends of the pintles simultaneously. The working parts are adjustable to suit rivets of varying lengths.

Fig. 4353 is a machine for riveting hinges. Peculiarly shaped revolving milling-tools spread the pintle when forced against it, and form the head.

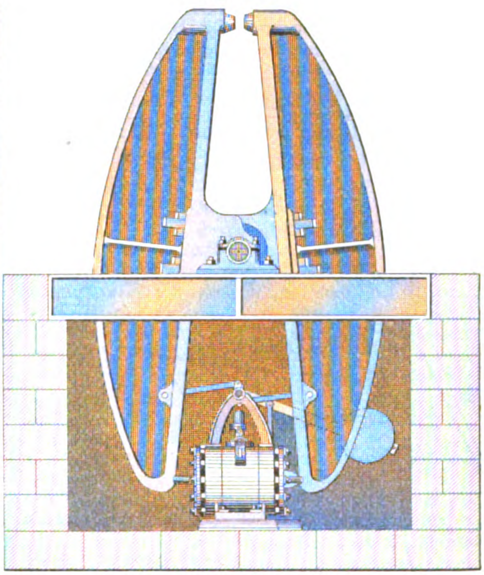
Fig. 4353.



Machine for Riveting Hinges.

McKay and Macgeorge's hydraulic riveter is operated by water from an accumulator under a pressure of 700 pounds to the inch; water is admitted to a small cylinder, causing the dies to close upon the rivet, when self-acting valves admit the water to the large cylinder, which compresses the plates together and finishes the riveting. After allowing the rivet a moment to cool, the handle operating the valves is reversed, when the jaws unclose.

Fig. 4354.



Hydraulic Riveting-Machine.

Riv′et-ing-set. A punch (*c*, Fig. 4344) with a hollow face, used for swaging the heads of rivets. It is more expeditious than the peen of a riveting-hammer, and by making the concavity of any desired shape, the counterpart form is imparted to the end of the rivet.

Riv′et-joint. The results of Mr. Fairbairn's experiments on riveted joints were as follows: —

Taking the coefficient of tenacity of the boiler-plate itself = 100

Then that of an equal length of joint would be —

For double row of rivets .... = 70
For single row of rivets .... = 56

Mr. Fairbairn gives the following table as exhibiting the strongest forms and best proportions of riveted joints, deduced from practice: —

Dimensions in inches.

Thickness of plate.	Diameter for rivets.	Length of rivets from the head.	Distance of rivets, center to center.	Depth of lap for single joints.
.19	.38	.88	1.25	1.25
.25	.50	1.13	1.50	1.50
.31	.63	1.38	1.63	1.88
.38	.75	1.63	1.75	2.00

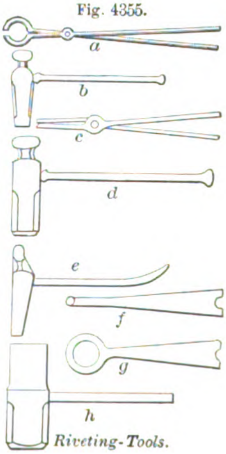
For double-riveted joints, add two thirds to the depth of lap given for single joints.

Riv′et-ing-tools. The implements used in riveting metallic plates together. Those used for ship and boiler plates are: —

Fig. 4355.



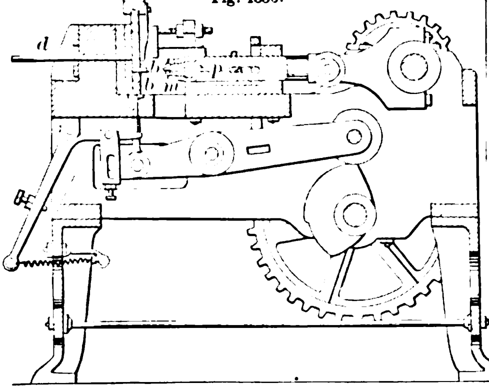
Riveting-Tools.

a, rivet-tongs.
b, riveting-hammer (outside).
c, tongs.
d, closing-hammer (outside).
e, closing-hammer (inside).
f, *g*, dolly.
h, holding-up hammer (inside).

Coppersmiths and other workmen in thin sheet-metal or leather work united by rivets, employ a *rivet-punch* or *rivet* and *burr set*, the work being supported on a stake or plate.

Riv′et-mak′ing Ma-chine′. A machine for making rivets from rod-iron. In Fig. 4356, the rod

Fig. 4356.

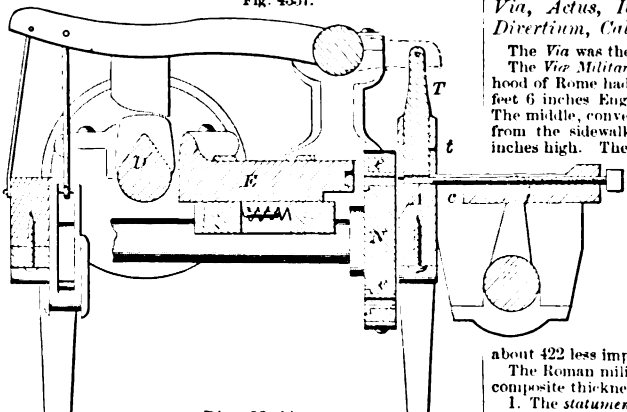


Rivet-Making Machine.

d is fed through a guide-plate into movable dies *b b*, the length of the blank being regulated by a stop. The movable dies have reciprocating motion, and cut off the rod fed into the machine, carry the blank in front of the heading die, and finally serve as the die in which the head of the bolt is formed. As they descend they cut off the length of rod against the face of the guide-plate, and carry it in front of a hollow die *m* that has a horizontal motion, the interior of the die corresponding to the intended form of the shank of the rivet. The stub end of the rivet is formed against the plunger *p*, which also serves to eject it when finished.

Fig. 4357 has a feed-plate *A* into which the rod is fed through an aperture *t*; a blank is cut off by the downward motion of the plunger *T*, which holds and guides it while being forced into one of the apertures *e e* in the die-wheel *N*, by the reciprocating rod *c*, where it is subjected to the action of the header *E*, operated by the same compound cam *D* which actuates the lever carrying the plunger *T*.

Fig. 4357.



Rivet-Machine.

Riv′ing-knife. (*Coopering.*) A tool used in splitting balks for staves, clapboards, shingles, etc. A *frow.*

Riv′ing-ma-chine′. A machine for splitting wood in the direction of the grain; for hoops, staves, splints, as the case may be.

Roach. (*Nautical.*) The upward curve of the foot of a sail, made in order to clear the stays, spars, etc. A piece laced on to fill up the concavity is called a *save-all.*

Road. "The Carthagenians," says an ancient writer, "invented paved roads." The Roman roads were pavements resting on a foundation of rough stones consolidated into one mass by liquid mortar or grout. They extended from Rome to her distant provinces, and facilitated the march of her legions, the transportation of supplies, and the intercourse by couriers and post-carriages.

"The Romans," says Isidore, "make roads almost all over the world, to have their marches in a straight line and to employ the people." Isidore was a Greek architect of the sixth century, and was employed by Justinian to complete the church of St. Sophia at Constantinople, now a Mohammedan mosque.

Twenty-nine great military roads centered at Rome, some of them being carried to the extreme limits of the Empire, which was divided into 11 regions, 113 provinces, traversed by 372 great roads, which, according to the Itinerary of Antoninus, had a length of 52,964 Roman miles.

The first of these great roads was the *Appian Way*, constructed by the censor Appius Claudius Cæcus, 442 A. U. C. (311 B. C.), who is not to be confounded with the decemvir Appius Claudius, 449 B. C., concerned in the tragedy of Virginia, the Roman maiden. The stones were hewn and carefully fitted. It was never excelled by the Romans. Appius constructed it to Capua, 142 miles, and his successors to Brundusium (now Brindisi), another 218 miles. Strabo (d. A. D. 24) gives it the preeminence. It is still entire in many places, though more than twenty centuries have elapsed since its construction. It was properly called "Regina Viarum."

The Via Numicia led to Brundusium; the Via Flaminia to Rimini and Aquileia; the Via Aurelia was along the coast of Etruria; the Via Cassia ran to Modena, between the Flaminian and Aurelian ways; the Via Æmilia extended from Rimini to Piacenza.

The smaller ways were the Via Prænestina to Palestrina (the ancient Præneste); Tiburtina to Tivoli; Ostiensis to Ostia; Laurentina to Laurentum, south of Ostia; Salaria, etc.

Under Julius Cæsar the capital of the Empire was in complete communication with all the principal cities by paved roads. During the last African war a paved road was constructed through Spain and Gaul to the Alps.

These roads connected the capital with Savoy, Dauphiné, and Provence, Germany, all parts of Spain, Gaul, Constantinople, Hungary, Macedonia, and the mouths of the Danube.

On the other sides of the intervening waters these roads were continued in Sicily, Corsica, Sardinia, England, Asia, and Africa.

The Roman roads were distinguished by the names *Via*, *Actus*, *Iter*, *Semita*, *Trames*, *Diverticulum*, *Divertium*, *Callais*, etc.

The *Via* was the best, and had a width of 8 Roman feet.

The *Viæ Militari* and other important roads in the neighborhood of Rome had a double width, 16 Roman feet, equal to 15 feet 6 inches English, and *margines*, or sidewalks, 8 feet wide. The middle, convex portion was paved with blocks and divided from the sidewalk by a curb or low wall, 2 feet wide and 18 inches high. The middle was for the infantry; the margines for carriages and equestrians.

The *Actus* was 4 feet wide, for single carriages.

The *Iter*, for horsemen, pack animals, and pedestrians, was 3 feet wide.

The *Semita* was 18 inches wide, and was called *Trames*, *Diverticulum*, or *Divertium* when it branched across fields. The *Semita* on steep grades was frequently in the form of steps.

The *Callais* was a mountain path.

In Rome were 31 principal streets and about 422 less important ones.

The Roman military roads were made with four strata with a composite thickness of about three feet.

1. The *statumen* consisted of two courses of flat stones laid in mortar.

2. The *rudus*, a rubble of broken stones mixed with one third the quantity of quicklime and well rammed.

3. The *nucleus*, a mixture of brick, potsherds, broken tiles, and one third the quantity of lime; or gravel and the stated proportion of lime laid on while hot from slaking.

4. The *summa crusta*, pavement of not less than six inches thick.

These roads bore uninjured the weight of columns, obelisks, and other immense blocks, weighing hundreds of tons.

The royal roads of Persia ran by the side of the common roads, and were reserved for the uses of the king alone. They were kept in better condition than the common roads, and gave rise to that remark of Euclid, the mathematician, to Ptolemy Philadelphus, at a dinner in the Museum of Alexandria, "There is no royal road to geometry."

The Moguls constructed good roads in India, with a distance-stone at the end of every *koss*. Agra, Lahore, and Cashmere were thus connected. With the death of Aurungzebe these improvements ceased, and the works commenced to decay.

At a comparatively late date the work of improvement of the Indian roads has been pursued with vigor. The Grand Trunk Road connects Calcutta with Peshawur on the borders of Affghanistan.

The military roads of Peru were built, one on the plateau, the other on the shore. The former, for nearly 2,000 miles, crossed sierras, gorges, and rivers, by tunnels, bridges, and ferries. The road was 20 feet wide, faced with flags covered with bitumen, and had milestones. The shore road was built on an embankment, with a clay parapet on each side, and shade-trees. It was supported by piles, in places. Every five miles there was a post-house. Humboldt declares the road magnificent.

We learn from the venerable Bede (A. D. 700) that the Roman roads of England were built at various periods in the second, third, and fourth centuries; the people, criminals, and the Roman soldiery being employed thereon.

The four principal ones were, —

1. Watling Street; from Kent, by way of London, to Cardigan Bay, in Wales.

2. Ikenild Street; from St. David's, Wales, by way of Birmingham, Derby, and York, to Tynemouth, England.

3. Fosse Way; from Cornwall to Lincoln.

4. Ermin Street; from St. David's to Southampton.

In many places the remains are yet visible; in many others the old pavement is below the surface, having been buried by the vegetable growth of centuries, or covered by earth from other natural cause, such as land-slips and watercourses.

Highways were first made public in many parts of England by the Romans. In the time of Edward I. they were ordered to be widened and cleared of trees within 200 feet of the road, for the prevention of robberies. Toll was granted on one in London in 1346. The parishes were made answerable for their condition in 1553. Toll-gates were erected in 1663.

In the sixteenth year of the reign of the frivolous Charles II. a turnpike road was established through Hertfordshire, Cambridgeshire, and Huntingdonshire.

The Simplon road from Geneva to Milan, built by Napoleon, cost the French government 17,000,000 livres ($ 3,250,000).

MacAdam says: "The measure of substituting pavements for convenient and useful roads is a kind of desperate remedy, to which ignorance has had recourse."

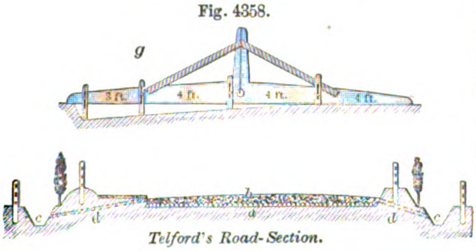
The mode of road-making with broken stone, before MacAdam, was to make a foundation of large stone, on them place stones of a medium size, and finish off with the smallest. MacAdam employs broken stone of as hard a variety as possible, no stone to exceed six ounces in weight. A ring is used to test the sizes. It has an interior diameter of 2½ inches.

The convexity of a road of 50 feet width may be 1 foot when settled; 6 inches more should be allowed in making.

MacAdam, by the authority of the Parliamentary Commission, substituted in one street for the rounded stones or bowlders a bed of broken stone laid as a convex rounded roadway. His ideas were laughed at by professional road-makers, but after a trial of the new scheme, the paving of London was torn up, broken, and spread *à la Macadam*. The country districts soon followed the example. MacAdam was made Surveyor-General of the Bristol Roads; he was reimbursed for his expenses, and received the additional sum of £2,000 as a recognition of his services.

The section (Fig. 4358) illustrates a plan successfully adopted by Telford on the Glasgow and Carlisle, the Holyhead, and other roads. It consists of a foundation *a* of paving-stones laid broad end downward on the leveled surface of the natural earth and covered with broken stones *b* to the depth of about six inches. These wedge in between the interstices of the foundation, forming a smooth and compact surface. *c c* are ditches, and *d d* pipe-drains.

Fig. 4358.



Telford's Road-Section.

The National Road from Baltimore, across the Alleghanies and extending to Illinois, is 650⅜ miles in length and 80 feet in width. It is macadamized for a width of 30 feet.

Road-bed. 1. (*Railway Engineering.*) The bed or foundation on which the superstructure of a railway rests. The substructure of the way consists of the embankment, bridges, piling, ballast, etc., and supports the superstructure, which consists of the rails, ties, chairs, frogs, crossings, etc.

2. (*Civil Engineering.*) In common roads, the whole material laid in place and ready for travel.

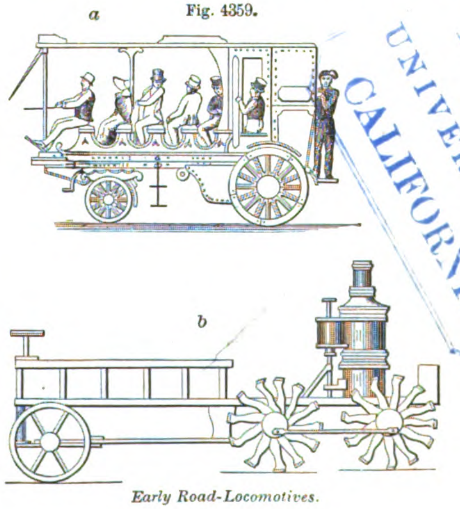
Road-lev′el. A level (*g*, Fig. 4358) for correctly laying off the surfaces of common or macadamized roads. Its lower edge is set horizontally by the aid of a plumb-bob suspended from its upper branch, and the lower limb is provided with offsets, adjustable by means of screws, which are raised or lowered relatively to each other to guide the workmen in forming the desired slope.

Road-lo′co-mo′tive. A locomotive adapted to run on common roads. The idea, conceived by Watt and Dr. Robinson, was first realized by Murdoch, a Cornish engineer, who, about 1786, constructed a small locomotive which ran on the high-road near Redruth. William Symington, in Scotland, and Oliver Evans, in America, also constructed models, though on different plans, of engines designed for this purpose. In 1802, Trevethick and Vivian had one experimentally in operation. After this the badness of the roads and opposition of the turnpike managers, or the diversion of inventive talent to the improvement of railways and their appliances, seem to have frustrated farther attempts in this direction for many years, when the subject was taken up by Griffiths, Brunel, Gurney, and others at various times. See LOCOMOTIVE.

Steam-carriages constructed by some of these inventors plied for a time between various cities and towns in England and Scotland, but failed to become profitable.

One of Gurney's engines, weighing two tons, drew

Fig. 4359.



Early Road-Locomotives.

11 tons upon a good hard country road. The drivers of this locomotive had tires $3\frac{1}{2}$ inches wide.

Hancock's engine (*a*, Fig. 4359) ran for hire with 16 passengers in 1831. The machinery was situated behind the carriage. The fire was blown by a revolving fan turned by the engine. The two hind wheels were drivers, though one was generally disconnected from the engine, except in climbing hills, etc. The weight of the locomotive, with water and fuel, but without passengers, was $3\frac{1}{2}$ tons.

The success of railways, and the difficulties attending the use of locomotives on ordinary roads, caused a cessation of efforts toward their improvement until about the year 1856, when the subject was again revived with a view to the adaptation of such engines to agricultural purposes. Of late years, several varieties have been constructed, which fulfill their intended purpose with considerable success. The more prominent of these are constructed on the general plans of Ransome and Sims, or of R. W. Thomson of Edinburgh, who introduced the flexible rubber tire.

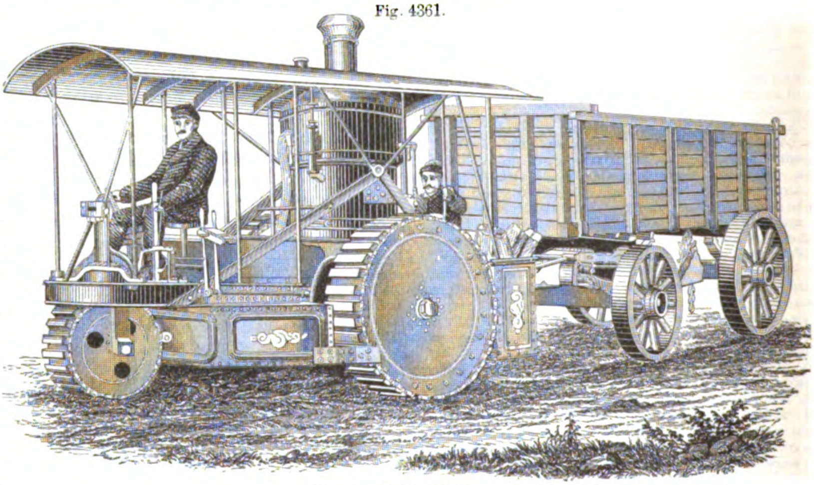
James's (*b*, Fig. 4359), patented in 1867, is one of the earlier of the more recent American efforts in this line. It has coupled drive-wheels, the tread of which consists of segments of a circle supported on separate spokes.

Ransome and Sims's "self-moving engine" (Fig. 4360) is adapted for hauling light loads on common roads.

These engines have a single cylinder. The driver and steersman are placed behind the engine, thus enabling them to communicate with and assist each other. All the apparatus for starting the engine, reversing and applying the brake, are placed close together; and the gearing for communicating the motion to the driving-wheels is so constructed that both wheels are always in gear even when turning a sharp corner.

By an adjustment of the driving-pinions the speed of the engine may be altered from the slow speed of $2\frac{1}{2}$ miles per hour to 4 miles per hour, and *vice versa*. The driving-wheels *a a* are wrought-iron, with cast-iron rims, 10 inches broad. They are furnished with wrought-iron spuds to attach to the rims in case the roads are very sandy and soft. The fire-box of the engine is adapted to burn wood or coal. Coal and water for a journey of from 6 to 8 miles may be stored in the tanks *e f* under and at the back part of the engine; *b*, fly-wheel; *c*, rudder-post; *d*, steering-wheel. This locomotive is also adapted for use as a motor for thrashing-machines, saw-mills, etc.

Fig. 4361.



Thomson's Road-Steamer.

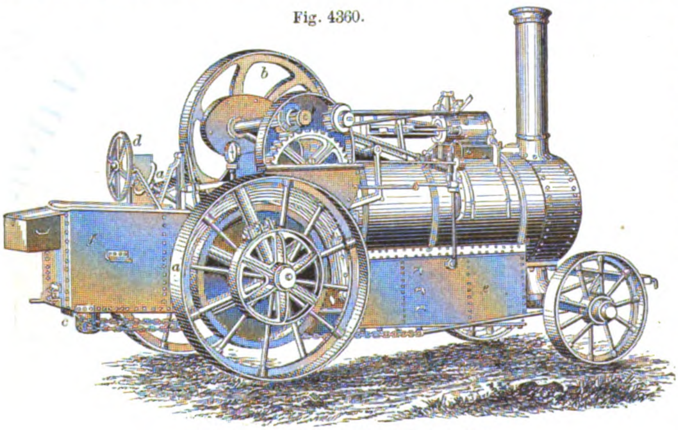
Thomson's (Fig. 4361) has an upright tubular boiler and two small cylinders. The crank-shaft and drivers are connected by gearing.

The great novelty of this engine is in the elastic tires of the wheels, adapting them to pass over loose stones, slippery surfaces, etc. These tires are of rubber, 12 inches wide and $4\frac{1}{2}$ inches thick. The rim of the driver is perforated with a large number of holes, an inch or more in diameter, into which the inner surface of the rubber tire forces itself, to prevent slipping. The outside of the tire is protected from injury, to some extent, by an endless band of steel cross-bars, which yield with the tire to inequalities of ground.

The locomotive is steered by a single pivoted wheel in front, and is able to turn in very small space. By a little change in the machinery, it may also be used as a portable engine. See ROAD-ROLLER.

Road-locomotives are employed to some extent in England and in British India, but have not met with much favor in continental Europe or America. A few are in use in Brazil, and in the United States several kinds are manufactured to order; but the demand for them is, at present, not great. See TRACTION-ENGINE.

Fig. 4360.



Ransome and Sims's Road-Locomotive.

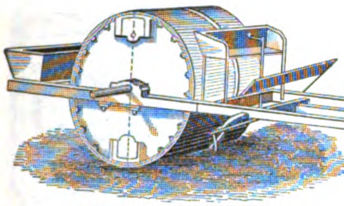
Road-met'al. (*Engineering.*) Broken stone for making or mending macadam roads.

Road-roll'er. A heavy cylinder used for compacting the surfaces of roads.

One of the road-rollers used in the Central Park, New York, weighs $6\frac{1}{4}$ tons, and is adapted to receive additional loading to bring it to 9 or 12 tons. It is composed of two hollow cylinders of cast-iron, set abreast on

a strong wrought-iron axle, making together a length of 5 feet, with a diameter of 7 feet; the cylinders are set in a timber framework, so arranged as to admit of being suitably balanced

Fig. 4362.



Central Park Road-Roller.

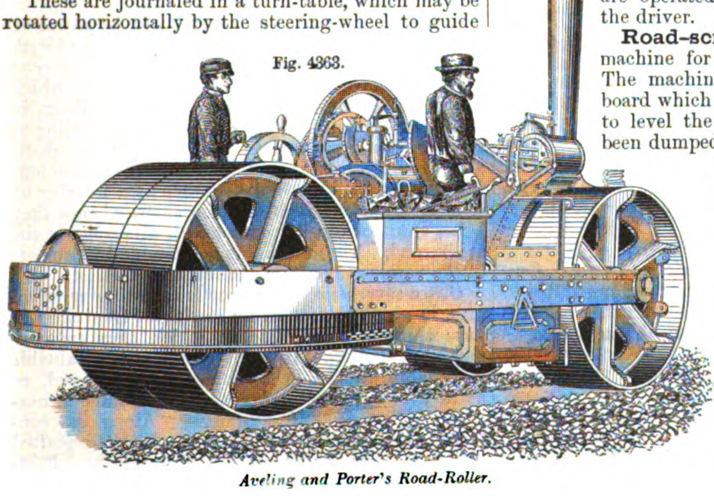
on the journals, and the whole is drawn by eight horses. Apertures are made in the ends of the cylinders, through which the interior cavities, consisting of four separate cells in each cylinder, can be filled with broken stone and gravel, and the weight thereby increased up to 12 tons, as above stated. Two of these large rollers were constructed at the commencement of the work, and have served, until lately with but few repairs, for the entire road-system of the Park.

Steam road-rollers have now been generally introduced with great success.

Aveling and Porter's (Fig. 4363) has two driving-rollers in front, one of which turns loose on the axle to enable the machine to turn short curves. The driving-axle is rotated by chain gearing from the crank-shaft, and similar gearing is used for connecting the steering-wheel with the two large rollers at the rear of the machine.

These are journaled in a turn-table, which may be rotated horizontally by the steering-wheel to guide the machine in any direction. It is built of four sizes, weighing respectively 15, 20, 25, and 30 tons.

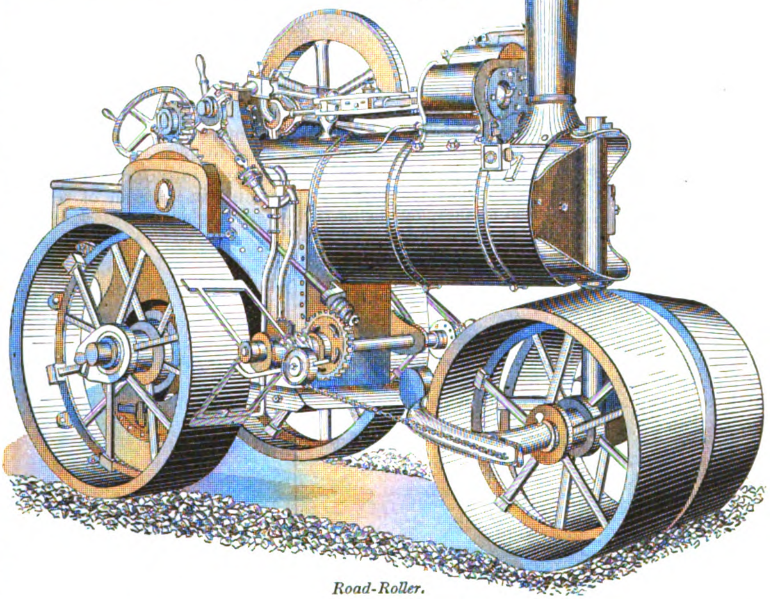
Fig. 4363.



Aveling and Porter's Road-Roller.

The steering-wheels of a differently arranged roller, made by Aveling and Porter (Fig. 4364), are somewhat conical, and are mounted on an axle, whose ends are bent downward, so that the wheels are close together at their lower edges, while between their upper edges a strong upwardly projecting center-pin from the axle passing through flanges at the end of the fire-box serves to support that part of the boiler, and as an axis on which the fore-wheels turn to steer the machine. The steerage is effected by chains connected to the bow in which the axle is journaled, which are operated by a foot-plate worked by the driver.

Fig 4364.



Road-Roller.

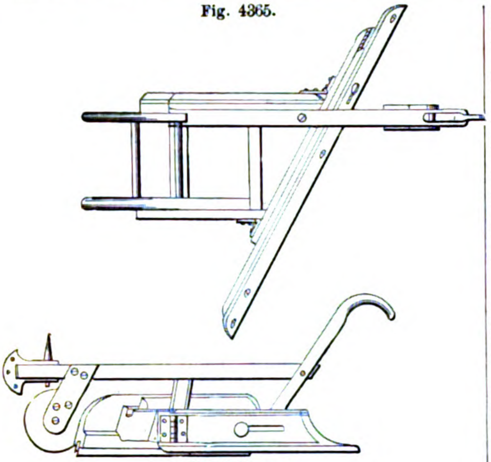
Road-scrap′er. A large hoe, or a machine for leveling or cleaning roads. The machine (Fig. 4365) is an oblique board which is drawn over the road-bed to level the earth or gravel which has been dumped in position. It is also used in rounding-up country roads after plowing a number of furrows on each side.

Fig. 4366 is a common form of scraper for removing earth in road-making, or even in ditching when the sides of the excavation are sloping. A *grading-shovel* or *earth-scraper*.

Fig. 4367 is a machine having shares, scrapers, and roller attached to the frame. It is intended for leveling roads.

Road-steam′er. A lo-

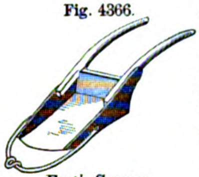
Fig. 4365.



Road-Scraper.

comotive traction-engine for use on common roads. See ROAD-LOCOMOTIVE ; TRACTION-ENGINE.

Fig. 4366.

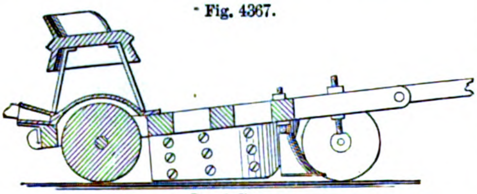


Earth-Scraper.

Roan. (*Leather.*) Sheep-skin tanned with sumach; the process is similar in its details to that employed for morocco leather, but lacks the *graining* given to the morocco by the grooved rollers in the finishing. It is used largely for bookbinding and somewhat for shoes.

Roast'ing. (*Metallurgy.*) A protracted heating of metallic ores to a point below fusion, to expel sulphur, arsenic, carbonic acid, water, etc., and frequently to effect oxidation.

Fig. 4367.



Road-Scraper.

The roasting of ores is conducted in heaps or furnaces.

The operation is (*a*) for the purpose of removing impurities, or (*b*) for converting certain constituents into a more tractable condition, either for succeeding operations or for removal.

1. Sulphur and arsenic are expelled by fire, passing off in fumes. This is termed roasting with iron and some other ores, which are built up into heaps with fuel and then fired.

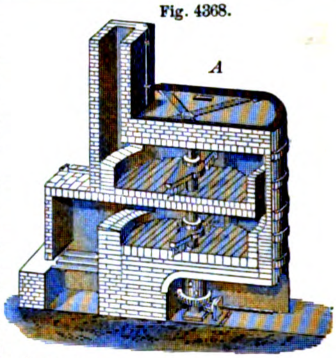
2. The roasting of *tin* ores to get rid of iron and zinc is conducted in a reverberatory furnace. Copper ore is roasted in a similar furnace or smelted to convert the sulphuret of iron into an oxide, when it passes into the scoriæ and is removable as a slag.

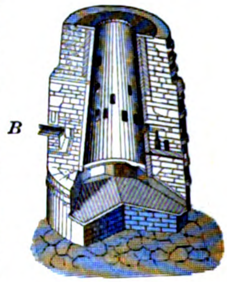
See COPPER ; COPPER-SMELTING ; CALCINING-FURNACE ; ROASTING-FURNACE ; DESULPHURIZING-FURNACE, etc. See lists under METALLURGY ; FURNACE.

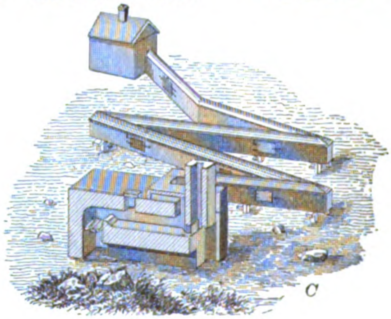
Roast'ing-bed. (*Metallurgy.*) A floor or bed of refractory substance on which ores are roasted.

Roast'ing-fur'nace. (*Metallurgy.*) A furnace in which ore is heated to drive off the sulphur and other volatile particles.

Fig. 4368.







Roasting-Furnaces.

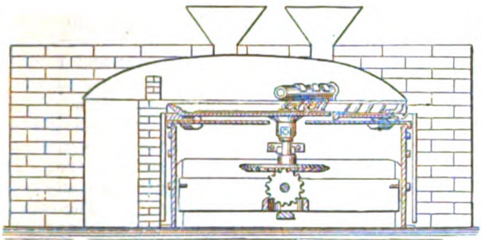
A is Parke's roasting-oven for copper ore, in which the ore is stirred by machinery. The hearth is in two stories, each of which has its own rotary stirrer attached to the central shaft and operated by gearing in the vault below. The hot gases from the furnace pass over the two chambers in turn, and thence to the chimney. The hearths are about 12 feet in diameter. On the other side of the hearth appear the openings at which the working tools are introduced. These are closed by iron doors. The charge is introduced at an opening in the roof of the upper chamber. Each hearth has a charge of 4 tons. The material is raked from one floor to the other, and eventually falls into a vault beneath.

B is a shaft-furnace for roasting iron by means of gases from hydrocarbons. The stack is hooped with iron, and has a central cavity of a truncated cone shape. The cast-iron hearth has three slopes which incline to the discharge-holes, which have doors in which are air-holes. Above the openings leading to the doors is a carrying piece projecting into the shaft. The gases are led in at a tube shown on the left, from which they reach the interior by a number of tuyeres at various hights in the shaft, whence they issue, and, coming in contact with atmospheric air, are burned. The entrance is regulatable by dampers at the various tuyeres of the respective series.

C is a reverberatory furnace for roasting arsenical ores, in which the fumes are conducted from the furnace through a long flue, in which they are condensed in cooling. By such means either valuable materials are saved, or the fumes are suppressed, so as to avoid contaminating the surrounding atmosphere. See ARSENIC-FURNACE. Along the condenser are doors for extraction of the deposited material. See Plattner's "Metallurgischen Röstprozesse," Freiburg, 1836.

Fig. 4369 is a furnace with a rotating hearth, the contents of which are moved by stationary stirrers.

Fig. 4369.

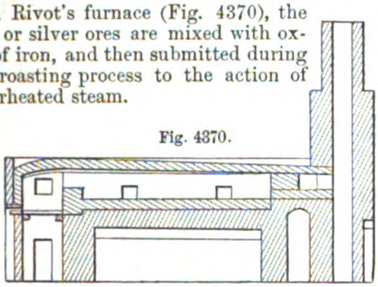


Revolving-Hearth Furnace.

Another form of roasting-furnace has inclined cylinders, through which the ores pass, being heated by the furnace.

In Rivot's furnace (Fig. 4370), the gold or silver ores are mixed with oxide of iron, and then submitted during the roasting process to the action of superheated steam.

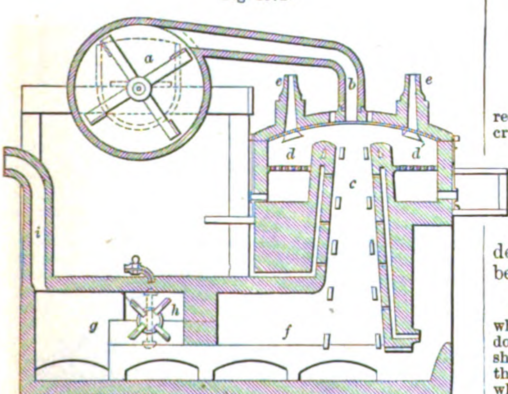
Fig. 4370.



Reverberatory Furnace.

In Whelpley and Storer's furnace, patented January 12, 1864, the ore, in a finely comminuted state, is forced by a fan-blower *a* through the tube *b* into the descending shaft *c* of the apparatus; this has furnaces *d d′* on each side, provided with chimneys *e e*, to the action of which the ore falling from the tube *b* is exposed. The bottom of the horizontal

Fig. 4371.



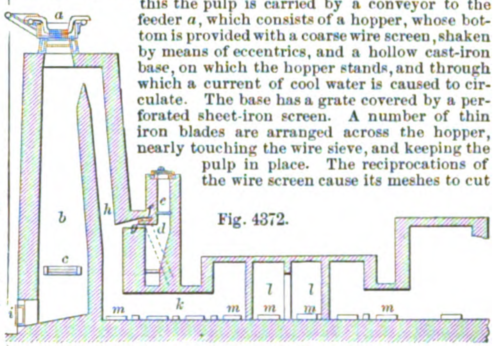
Whelpley and Storer's Shaft-Furnace.

shaft *f* is covered with water, into which the heavier particles of ore fall; the lighter portions are arrested in the chamber *g* by means of a spray of water injected thereinto. A rapidly revolving fan *h* in this chamber withdraws the products of combustion through the up-cast shaft *i*.

Stetefeldt's furnace for roasting silver ores is of the class known as a *shaft*-furnace, in which the powdered ore is calcined while falling through the flame rising from a fire.

The ore, having been crushed by the rock-breaker, is then mixed with salt and pulverized by the stamp battery. From this the pulp is carried by a conveyor to the feeder *a*, which consists of a hopper, whose bottom is provided with a coarse wire screen, shaken by means of eccentrics, and a hollow cast-iron base, on which the hopper stands, and through which a current of cool water is caused to circulate. The base has a grate covered by a perforated sheet-iron screen. A number of thin iron blades are arranged across the hopper, nearly touching the wire sieve, and keeping the pulp in place. The reciprocations of the wire screen cause its meshes to cut

Fig. 4372.

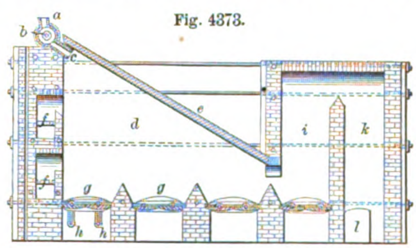


Stetefeldt Roasting-Furnace.

through the pulp, which falls into the shaft *b* in a continuous shower. *c* is one of two flues of a gas-generator, which enter the shaft on each side. The shaft *d* is provided with a light cover and a slide *e*, on which charcoal is burned. The carbonic oxide produced by this is mingled with air introduced through the flue *f*, and passes in a state of ignition through the shaft *g* into *h*, where it heats the shower of falling pulp, which is thus desulphurized and dechloridized, and falls upon the inclined bottom of the shaft, whence it is withdrawn through the door *i*. The fine particles, freed from sulphur and chloridized, which pass through the shaft *h*, are deposited in the flue *k* and dust-chambers *l l*, and withdrawn at intervals. See page 1571.

In Aiken's furnace (Fig. 4373), the stamped ore fed through the aperture *a* is conveyed by the screw *b* into the conductor *c*, and drops into the roasting-chamber *d*: this has an inclined arched top *e*, and is heated by two furnaces *f f*, which open di-

Fig. 4373.



Aiken's Roasting-Furnace.

rectly into the chamber; the doors *g g*, pivoted, and having cranks *h h* by which they may be placed in horizontal or vertical position, serve to discharge the roasted pulp; the waste gases after passing through the ascending and descending shafts *i k* and flue *l*, serve to dry the ore previous to stamping.

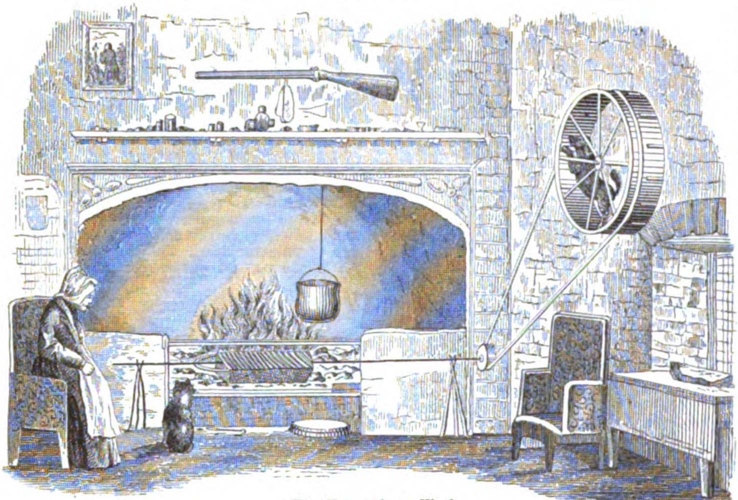
Roast′ing-jack. (*Domestic.*) An old-fashioned device for turning the spit on which meat was roasted before an open fire.

It was driven by a dog inclosed within a tread-wheel from which a belt passed around a pulley on the end of the spit. The dogs employed for this purpose usually belonged to a peculiarly short-legged, long-bodied breed, termed *turnspits*. It is said that there was not unfrequently considerable competition as to which should take his place in the wheel when a joint was to be roasted, the animals well knowing that industry would receive its reward.

In the onward march of improvement, this device disappeared before its younger rival, the smoke-jack, which ate nothing; though within a comparatively recent period it might still be occasionally met with in England.

Its faithful minister, the turnspit dog, is now but rarely seen. The illustration is taken from the castle of St. Briard, on the borders of the Forest of Dean, in Gloucestershire, and forcibly suggests the days when the "roast beef of Old England" still maintained its time-honored supremacy over mutton and such small deer.

Fig. 4374.



The Turnspit at Work.

tunnel and conveyed to the drill-cylinder by a pipe wound on a reel at the back of the apparatus, and so geared as to allow the pipe to unwind when the machine is advancing and recoil it when moving in the reverse direction. By suitably arranged gearing, the boring cylinder may be raised or lowered and adjusted to any required angle. The compressed air is cooled by being forced through water, enabling a higher pressure to be used, and may be diverted from the boring-cylinder to an upright cylinder, from which motion is transmitted to the wheels when it is desired to move the machine. See ROCK-DRILL.

In default of a turnspit dog, — which is not an uncommon animal, but the art of being thus useful has been lost in the family for several generations past, — the spit may be turned by means of a weight and cord acting over a pulley and wound upon a drum, on whose axis is a band-wheel which turns the spit by means of a cord. See BOTTLE-JACK; SMOKE-JACK.

Ro′band. (*Nautical.*) A piece of plaited rope called *sennit*, used for fastening the *head-rope* of a sail to the *jackstay*. A rope band.

Rob′i-net. (*Steam-engine.*) A British term (borrowed from the French) for some of the cocks of the steam-engine, as the *gage*, *brine*, and *trial* cocks.

Roch′ing-cask. A wooden cistern, lined with lead, in which alum is crystallized after having been previously dissolved in water or by the action of steam.

Rock′a-way. (*Vehicle.*) A kind of four-wheeled, two-seated carriage, with full standing top.

Rock-bor′ing Ma-chine′. (*Mining.*) A machine for drilling holes in rock. Low's machine is operated by air compressed in a reservoir at the mouth of the

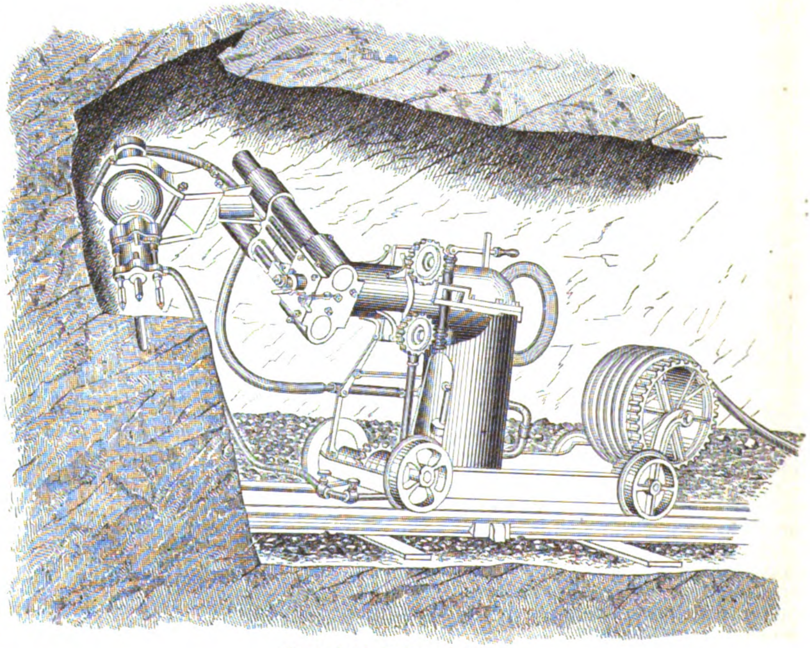
Rock-crush′er. A machine for breaking rock. See ORE-MILL; STAMPING-MILL; QUARTZ-MILL, etc. See lists under MILL; METALLURGY.

Rock-drill. A tool for boring rock by a chisel movement or rotary motion. Fig. 4376 shows several forms of rock-drills, embracing some of the peculiar features of this tool. Many varieties may be found not here shown, but these are representative. See also under ARTESIAN-WELL; WELL-BORING, etc.

a has four cutting edges, arranged radially.

b. The drill-stock has a central cutter and removable, reversible, radial cutters with extended edges. The shanks of the cutters are retained by a sleeve and key in the longitudinal recesses of the drill-stock.

Fig. 4375



Low's Rock-Boring Machine.

c has a central drill and four circumferential reamers to enlarge and trim the hole.

d is a drill of fast and movable flat chisel-formed cutters combined in one stock, in such a way that the movable cutter will be the leading cutter, and, after it has made its stroke, will receive a blow on its top end from the descent of the fast cutters, thereby driving it past them into the rock.

e has a central cutter operating in a tube which forms a sand-bucket.

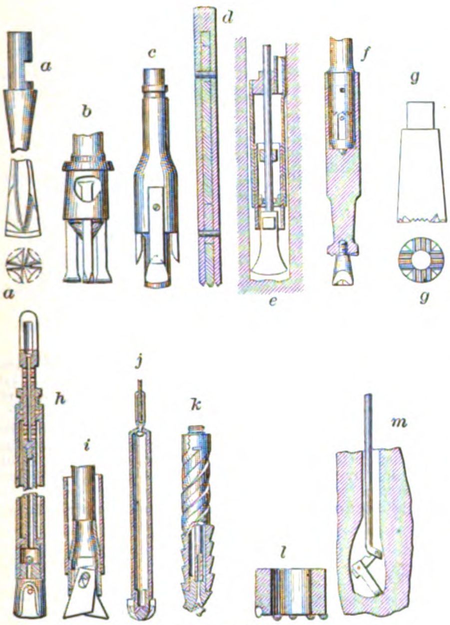
f has serrated sections, a collar and oblique grooves on the stock, so that as the shaft is lifted for a stroke, it is turned, causing the cutting face to descend in a new place, and turning the drill without the revolution of the stock.

g is a rock-drill of tubular form, and has on its face sets of cutting edges so arranged that the edges of one set may strike the rock across the incision made by the edges of the adjacent set.

h is designed to remove broken and pulverized rock from the bore of a well, and collect it in the drill-rod, at the same time discharging the water from the rod, so as to allow the heavier matters to be retained in the rod, until the receptacle there provided for them is filled

i is an expanding drill; when it is drawn upward the cutters

Fig. 4376.



Rock-Drills.

fall together and become contracted to a compass less than the diameter of the pipe within which the drill works; but when it is forced downward the cutters are forced outward in radial directions to a diameter greater than the pipe, and therefore cut a path for the pipe.

In *j* the drill-stock is hollow, and is designed to be provided with hose attachments for the purpose of introducing water under pressure into the hollow part of the drill-stock, in order to have the water issue therefrom through suitable apertures, to free the drill of the boring meal and remove the same by the overflow of the water.

k is a conical-pointed borer, having three curved cutting faces at equal distances around its point, and is connected with the base of a hollow cylinder by a socket-joint; its curved cutting faces take a spiral form and are continued up to the top of the cylinder, thereby forming parallel spiral grooves on the outside of the cylinder; the edges of the spiral grooves act as reamers, the grooves form elevators in which the silt is raised nearly to the top of the cylinder, where the grooves are intersected by openings which admit the silt to the inside of the cylinder, from which it is discharged, when full, by raising the instrument from the well and removing the borer.

l is an annular reamer whose face is armed with black diamonds or sapphires. See DIAMOND-DRILL.

m is a tool for making an enlarged chamber at the bottom of a shaft. It has a pair of chisel bars coupled by pivots and spreading laterally by the weight imposed.

Rock-drill′ing Ma-chine′. The two most important improvements in modern rock-drilling apparatus consist in the use of compressed air as a motor and the employment of diamond points. (See Fig. 1631.) The former is now universally used in operations on a large scale, as at the Mont Cenis and Hoosac tunnels, and is extensively employed in coal-mining, serving to ventilate the shaft besides performing the functions of a motor. The drilling-machines to which it is applied are various, very great improvements having been made within the past 20 or 25 years, previous to which time the old systems of turning the drill, and boring or pounding by hand, held undisputed sway.

In 1849, Clark and Motley, in England, invented a machine-drill, and in 1851, Fowle devised a similar machine, having the drill directly attached to the piston cross-head and provided with an automatic feed-apparatus. To this succeeded the Hotchkiss and Gardner machine. It has an automatic feed, and the drill is air-cushioned to deaden its shock, enabling it to be worked very rapidly without injury to the stationary parts.

The Mont Cenis and Hoosac tunnels gave a great impetus to this class of inventions, among which were a number intended for excavating the whole face of the boring at once. Such were those of Beaumont and Berrens. These were to cut an annular groove of the required circumference by means of drills rotated on a large cylinder-head, the core to be afterward removed by blasting.

Captain Penrice proposed to do away with blasting by studding the cylinder-head, to which a rotary and percussive motion was imparted, with a number of drills, so as to remove the whole face of the rock at the same operation. The smaller class of machines, which simply drill holes for containing a blasting charge, are those now universally employed. Among these are Bergstraem's, employed in Sweden, in which the drill is automatically rotated by a thread on the fly-wheel shaft, turning a gear-wheel on top of the cylinder and connected to the piston-rod; feed is effected by hand.

In Low's, the piston-rod is hollow and has an interior screw-thread by which the drill-holder, fitting therein, is advanced. The piston-rod is guided straight during the forward stroke by a ratchet-wheel, working in parallel grooves, which is partially rotated at each back stroke. See Fig. 4375.

The Burleigh machine, used at the Hoosac Tunnel and Hallett's Point, has a piston-rod extending both ways from the piston; the front end contains the drill, and the upper is hollow to receive the feed-screw; this part has a spiral slot, which receives a feather on the inner rim of a ratchet-wheel, by which a rotary motion is imparted on the up stroke; a ring on the end of the piston-bar also operates the valves, and through an intermediate lever feeds the drill.

In Ingersoll's, the piston-rod projects only in one direction (forward), and is hollow to receive a spiral guide for imparting rotation. The feed-screw works in a socket parallel with the cylinder, and is operated by a rod which passes through the spiral guide, and has a head which, by means of a crank movement, actuates the feeding-ratchet. The motor-valve is operated by plug-tappets at either end of the cylinder. Fig. 4377.

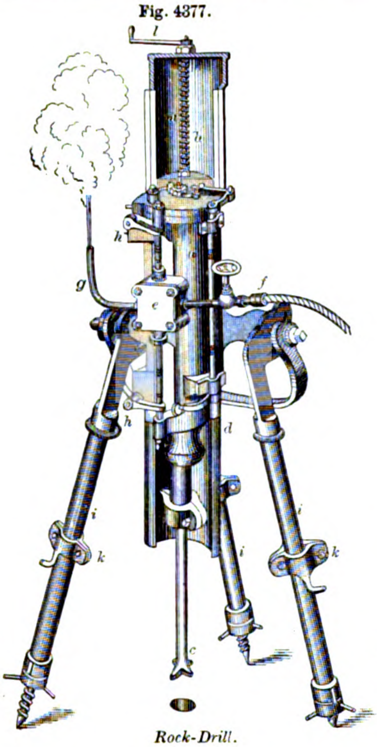
The Haupt drill is supported on four adjustable legs, and is sufficiently light to be moved by two men, and is operated by a single man with 2-horse power of steam; at 30 to 40 pounds pressure it drills a 1⅜-inch hole in hard limestone, at the rate of 5 inches per minute. Compressed air may be used, and the machine has the usual horizontal, angular, and vertical adjustments.

Shelburne's submarine rock-drill, employed for removing the obstructions at Hellgate, is supported on a semi-spheroidal hollow cast-iron base, having three steel feet, which insure its stability on the rock. The drill frame is conical in shape, and is made of wrought-iron, the drill-shaft passing through an opening in its top. The drill is operated by two engines within a water-tight chamber, and supplied with steam from the boiler of a steam-tug; its head is provided with diamond points, performing its work altogether by rotation. Live steam is supplied by a rubber pipe passing through an exterior exhaust-pipe. Electro-magnetic devices are caused to ring a bell when the hole is bored to the required depth, and also when the drill is removed from the hole. When the proper number are drilled, a diver descends and charges them with nitro-glycerine cartridges.

Colonel Von Schmidt, of San Francisco, has proposed to employ for tunneling the Sierra Nevada, in order to supply water to the auriferous gravel-beds of Placer County, an annular diamond-drill, eight feet in diameter, consisting of a large wheel, on whose edge the diamonds are set, cutting a circular groove two inches in diameter, and having a central borer, which drills a blast-hole. The apparatus is to be worked by compressed air; and when a sufficient depth is attained, 3 or 4 feet, it is to be run backward, and the cylindrical mass of rock removed by blasting.

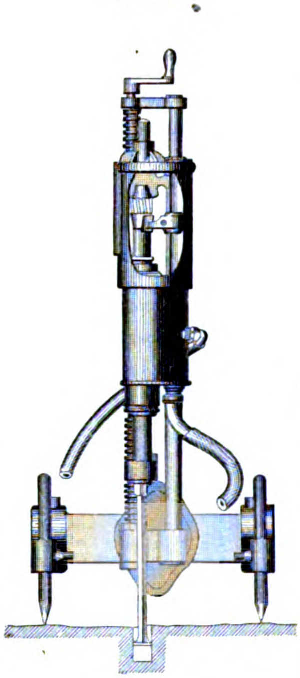
Ingersoll's rock-drill (Fig. 4377) may be worked either by steam or compressed air.

Fig. 4377.



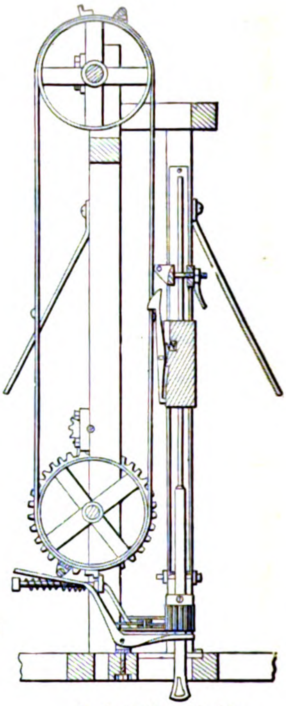
Rock-Drill.

Fig. 4378.



McKean's Rock-Drill (English).

Fig. 4379.



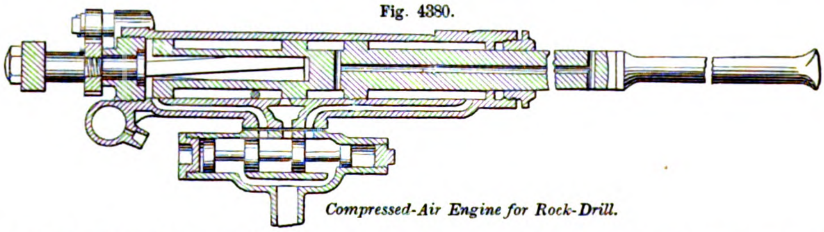
Rock-Drilling Machine.

The cylinder *a* is placed in a semi-cylindrical trough *b* having trunnions journaled in a tripod stand, is advanced by a screw as the hole is deepened, and may be rotated in a vertical plane to drill at any desired angle. The points of the hard steel drill *c* are so shaped as to exert a cutting instead of a crushing action, as the cylinder is rotated during its downward motion by ratchet and pawl devices operated from the rod *d*. *e* is the steam-chest, *f* the induction, and *g* the eduction pipe; *h h*, valve-rod tappets. The legs *i i i* are adjustable in length to suit inequalities of the ground, and are provided with hooks *k*, from which weights are suspended to hold the apparatus down to its work. *l* is a hand lever for turning the feed-screw *m*, in order to raise the cylinder. See also DIAMOND-DRILL, Figs. 1632, 1633, page 697.

McKean's rock-drill is operated by compressed air; the feed is effected by a hand crank and screw, and the drill is partially rotated at each stroke by a bevel-gear engaged by an inclined fin at each reciprocation. The stand is mounted on adjustable steady pins, by which it is leveled. See TUNNEL; SUBMARINE EXCAVATION.

Fig. 4379 is a view of a machine in which the boring is made by vertical strokes. The mechanism may be driven by hand or otherwise. The drill has its downward impulsion by a monkey which is automatically tripped. The drill has partial rotation between the strokes.

Fig. 4380.



Compressed-Air Engine for Rock-Drill.

Fig. 4380 is an air-driven reciprocating drill. The main cylinder, in addition to its ordinary ports, has two ports communicating respectively with the back of the valve of the cylinder and with the back of the advance cylinder. The main cylinder has also a central supply-port in constant communication with the fluid supply. The piston-rod carries three pistons forming two chambers. The forward chamber communicates with the outer air. The hinder chamber contains compressed air. The valve-rod carries four pistons; the two outer forming its operating pistons, and the inner ones the cylinder-valves.

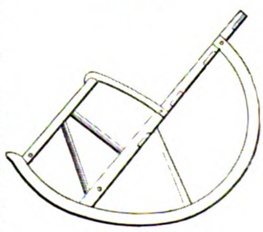
Rock'er. 1. (*Furniture.*) *a.* A curved piece into which the two legs on one side of a chair are inserted.

b. A curved piece beneath the end of a child's cradle.

2. (*Engraving.*) The comb-like steel tool used in making the ground-work of the mezzotint process.

3. (*Metallurgy.*) A trough mounted on rockers, and in which particles of ore are separated from earth by agitation in water.

Fig. 4381.

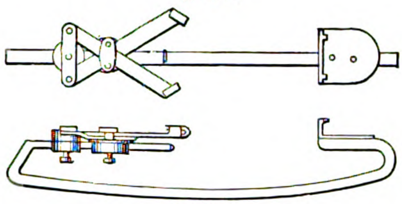


Rocking-Chair.

4. A low-down skate with a rounding sole.

5. (*Chemical.*) The congelation of a liquid is assisted by a slight agitation of its particles, which is effected in the ordinary process of freezing ice-cream by imparting an alternating

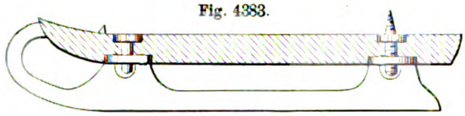
Fig. 4382.



Rocker.

semi-rotation to the vessel containing it. In Fig. 4384, the substance to be frozen is contained in a

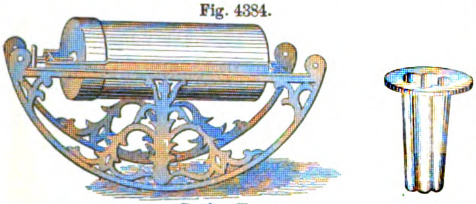
Fig. 4383.



Straight-Soled Skate.

mold, placed within a cylinder mounted on rockers, and is surrounded by a mixture of hydrochloric acid and sulphate of soda.

Fig. 4384.



Rocker-Freezer.

Rock'er-cam. (*Machinery.*) A vibrating cam.

Rock'er-shaft. (*Machinery.*) A shaft which oscillates about its axis, as that of a bell or one supporting a pendulum. More frequently called a ROCK-SHAFT (which see).

Rock'et. 1. A cylindrical tube of paper or metal filled with a compressed mixture of niter, sulphur, and charcoal, which, on being ignited, propels it forward by the action of the liberated gases against the atmosphere.

Rockets have been known in China and India from time immemorial, and have long been employed for war purposes. It seems probable, from the accounts, that they were employed against the forces of Alexander of Macedon at the farthest point of his Eastern advance.

The first European author by whom they are mentioned is Marcus Græcus, who, writing in the eighth century, says that if a compound of niter, sulphur, and charcoal be tightly rammed into a long narrow tube and set fire to, the tube will fly through the air.

They appear to have been employed against the Crusaders by the Saracens, and were probably first introduced by the former into Western Europe. War-rockets were used by the Venetians in 1380, and by the French in 1449. See GUNPOWDER.

Rockets are used for various purposes: —

War; in which the charge may amount to 32 pounds.

Life-saving; to convey a line to a stranded vessel.

Whale-killing; in which the charge may be 2 or 3 pounds.

Signal; fired straight upward, and not differing essentially from the ordinary.

Sky-rocket; a pyrotechnic device common in public displays.

Sky-rockets differ in their terminal display, which is dependent upon the *garniture* contained in a *pot* at the head of the case, and which may consist of *stars*, *golden showers*, *serpents*, *lardons*, *vetilles*, *petards*, *saxons*, *crackers*. See Ure, I. 729, 730.

These and signal rockets are made by rolling a rectangle of thick paper on a former, whose diameter is equal to the interior of the rocket. The paper is pasted at each turn, and additional sheets are added until the required thickness is attained. The *case*, as it is termed, is then *choked* near one end by wrapping it with strong twine, which is drawn tightly so as to compress it at that point, but leaving an opening sufficiently large to admit the *spindle*, on which it is placed for driving. The composition employed in the United States military service consists of about 26 parts niter, 5½ sulphur, and 19 charcoal from hard wood, preferably maple.

The niter and sulphur are pulverized, mixed by hand, and passed through a sieve having about 25 wires to the inch; the charcoal, moderately pulverized, is then incorporated by hand.

The case is placed, choke end downward, in a mold; the spindle, which projects upward about ⅔ the length of the case, having been inserted through the choke-hole; a ladleful of composition is poured into the case, and driven by means of a hollow copper-shod drift, which is struck 25 or 30 blows with a wooden mallet, packing the composition into a solid mass; another ladleful is then poured in and similarly driven; several hollow drifts are used, each shorter than the other, until the case has been charged to the top of the spindle, when a solid drift is employed. When the case has been charged to within about one diameter of its top, the charge is covered with a piece of paper, over which is placed a wad of clay or plaster of Paris.

Into this end a paper cylinder, termed a *pot*, is usually inserted for containing the *garniture* or decorations; it projects about 1½ diameters beyond the end of the case, and is surmounted by a paper cone.

The whole is attached to the larger end of a stick of square or rectangular section, and of such taper that the rocket will balance at a point on the stick one or two inches from the case.

The choked end is primed with a piece of quickmatch, and the rocket is fired from a stand which may be adjusted to any desired angle of elevation.

Desaguliers had proposed the use of rockets in modern warfare, but the first actually employed was introduced by Colonel, afterward Sir William, Congreve, in 1803.

The Congreve rocket consists of a sheet-iron case filled with a composition of niter, sulphur, and charcoal pulverized, and having a head which may be either solid or hollow, to contain a bursting charge, and is closed at bottom with a circular piece of gun-metal, having a central aperture, into which the stick is screwed, and smaller surrounding apertures for the escape of gases. If the shell-head be employed, it is provided with a fuse, so as to burst at or before the time of striking. These rockets were first employed in the attack on Boulogne, in 1806, and again at Copenhagen, in 1807. They were also used at the battle of Leipsic, 1813, by the British rocket troop, an organization which is still maintained in that service.

In Hale's rocket, the stick is dispensed with. As originally made, this rocket, which in external appearance resembles Congreve's, had a central aperture at the rear, through which the propelling gas escaped, surrounded by smaller tangential apertures for imparting rotation. These were employed by the United States army in the Mexican campaign of 1847, having been found to give generally as good results as those to which sticks were attached.

It sometimes, however, happened that immediately after starting one would diverge from a straight course and perhaps turn completely over, returning toward the place whence it was fired.

To obviate this, Mr. Hale placed the tangential directing apertures near the head, instead of at the base of the rocket.

The composition with which they are filled consists of niter, 10 parts; sulphur, 2; charcoal, 3. This is inserted in charges of about 3½ ounces each, which are successively compressed by a screw or hydraulic press, under a force of 20 tons or more to the square inch. A hole is bored axially through the composition, and afterward reamed out conically tapering toward the head.

A few rocket-batteries were organized in the early part of the late war, but most, if not all, of the material was subsequently turned into store. Rockets are, in fact, not adapted for use in a wooded country, not being susceptible of great accuracy of aim; and being diverted from their course by the slightest obstacle, they produce but little effect on disciplined troops, and are only available for firing buildings or frightening cavalry horses.

They were, however, used by the English forces in the war against Theodore, king of Abyssinia, — a lineal descendant, according to the tradition of his country, of the Queen of Sheba.

War-rockets are fired from a trough or tube, which has usually a stop near the muzzle end to detain the rocket until sufficient propulsive power is developed to insure its starting in the proper direction.

The tube is sometimes mounted on a tripod-stand and pivoted, so that the required direction and elevation may be given; or it is mounted on a carriage after the manner of a field-piece, in which case it is sometimes called a rocket-gun.

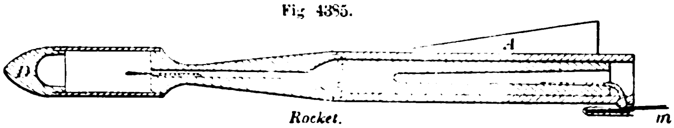
The tube has been made of rods of iron twisted spirally, so as to form a kind of lattice, imparting a rotary motion to the projectile; it has also been proposed to accomplish this object by flanges on the rocket itself.

Ranges.

12-pdr.	6-pdr.	Yards.	12-pdr.	6-pdr.	Yards.
...	7¾°	400	13½°	11¾°	900
...	8¾	500	14	12½	1000
10°	9¼	600	14¾	13¼	1100
11½	10½	700	15	14	1200
12¾	11¼	800	16	14½	1250

When the wind is directly against the direction of flight, half a degree is to be added to, and when directly favorable, the same amount is to be deducted from, the above elevations.

Fig. 4385.



Rocket.

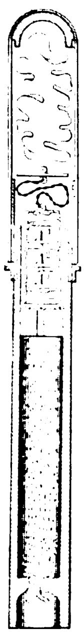
In Hunt's rocket, a stick is dispensed with, rotary motion is imparted by spiral wings on the case or tail-piece A, over which is a bursting charge to separate the head D therefrom at the termination of the upward flight. The rocket is fired by pulling a lanyard m, which draws a slide igniting a friction composition.

Walbach's rocket has wings and a percussion point, and an elbow to secure discharge if the point does not collide. A balancing piece on the threaded tail has spiral projections, which cause it to traverse toward the rear under the impulse of the blazing composition, and preserve the equilibrium as the composition is expended.

Detwiller's rocket has a series of interchangeable cups A^1 A^2 A^3, containing differently colored fires; these are interchangeable, so as to appear in any required succession when the head is exploded, their various combinations forming signals.

Fig. 4386.

Fig. 4387.



War-Rocket. *Signal-Rocket.*

2. The lever whereby the blacksmith's bellows are inflated.

Rock'et-drift. (*Pyrotechny.*) A cylinder of wood tipped with copper, employed for driving rockets. Its diameter is equal to the interior diameter of the case. Several of different lengths are used in charging each rocket, the shorter being employed as the case is gradually filled with composition; the longer have conical perforations to receive the *spindle;* the shortest is solid. Each ladleful of composition is compacted by striking the drift a certain number of blows with a mallet.

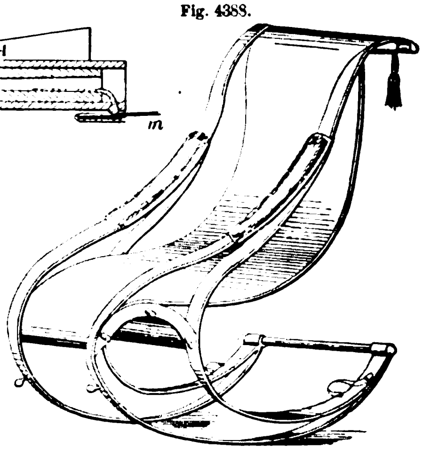
Rock'et-har-poon'. (*Weapon.*) A device for killing whales. It consists of a rocket having a pointed shell at its front end containing a bursting charge exploded by a time-fuse. The body of the rocket contains the propelling charge, and to its rear end is attached a barbed harpoon to which the line is fastened. It is fired from a gun or directing tube poised on the shoulder. See GUN-HARPOON.

Rock-fire. (*Pyrotechny.*) An incendiary composition which burns slowly and is difficult to extinguish. Used for setting fire to ships, buildings, etc. It is composed of 3 parts rosin, 4 sulphur, 10 niter, 1 regulus of antimony, 1 turpentine.

Rock'ing. The motion of a steel *mill* on a copper cylinder intended for calico-printing, when the pattern of the *mill* is to be repeated on the copper a number of times at intervals. See ENGRAVING-MACHINE.

Rock'ing-chair. One on curved pieces which allow a backward and forward oscillation. In Fig. 4388, the side pieces are connected by removable rods at the top under the seat and back of the rockers. Stops with springs attached prevent the chair rocking over.

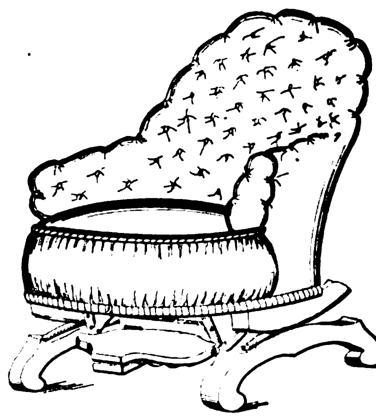
Fig. 4388.



Rocking-Chair.

When the chair (Fig. 4389) is used as a rocker, the leaf, foot-rest, and arms are folded under the seat. To place the chair in a condition to accommodate the body in a recumbent position, it is thrown back until the studs meet the hooks, after which the foot-rest is unfolded. The chair rocks to and fro on the base-piece instead of upon the carpet.

Fig. 4389.



Rocking and Reclining Chair.

Rock'ing-ham-ware. (*Pottery.*) See FAIENCE.

Rock'ing-tree. (*Weaving.*) The axle from which the *lay* is suspended.

Rock-pul'ver-iz'er. A machine or mill for breaking stone for road-bed or ore for metallurgic treatment. See ORE-MILL; STONE-BREAKER; QUARTZ-MILL, etc. See lists under MILL; MINING; METALLURGY.

Rock-shaft. (*Steam-engine.*) *a.* A shaft with tappets which raise the levers of the puppet-valves in a certain class of steam-engines.

b. The shaft, with levers, used for working the slide-valves, the notch of the eccentric rod dropping into a stud fixed in one of the levers; the links of the slide-valve spindle being attached to the opposite lever on the same shaft.

Rock-staff. The lever of a forge-bellows or other vibrating bar in a machine.

Rod. A straight, slender piece of wood or metal, as the ramrod, wiping-rod, rifling-rod, used by gunsmiths and armories.

The coupling bar or lengthening bar of a drill-stock.

A boring-bar; *miser; shell; sludger.*

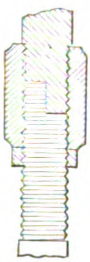
A connecting piece, as that between the cross-head of an engine and a crank. A *connecting-rod.* And so on.

Rod-chis'el. A chisel on the end of a withe or rod, used by the smith in cutting hot metal.

Rod-coup'ling. (*Well-sinking.*) A device for uniting the rods, which carry the tools used in boring Artesian or oil wells, etc., so as to form a continuous shaft.

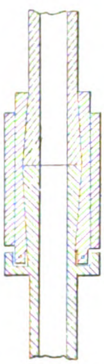
In Fig. 4390, the parts are halved together, screwed into a threaded sleeve, and secured by a jam nut.

Fig. 4390.



Pump-Rod Coupling.

Fig. 4391.

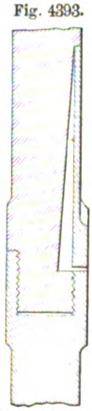


Rod-Coupling.

Fig. 4392.

Boring-Tool Coupling.

Fig. 4393.



Drill-Rod Coupling.

In Fig. 4391, the ends of the pipes have enlargements, and are secured by clamping, wedge-pieces, and an outer sleeve.

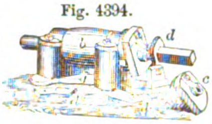
In Fig. 4392, the ends of the rods have annular channels, are clamped by half-cylinders similarly grooved, and secured by a tapering thimble.

In Fig. 4393, a recess in one section receives the end of a spring secured to the other section; the spring is depressed while the screw joint is being tightened, and when released by engagement with the recess prevents revolution.

Rod-ir'on. Rolled round iron for nails, fencing, etc.

Rod, Pin, and Dow'el Ma-chine'. (*Wood-working.*) A device for turning cylindrical dowels, rods, etc., from angular stuff. The frame *a* is secured to a stand, and carries the hollow rotating arbor *b*, to which the cutter-head *c* is clamped by a screw. The stuff is prevented from turning by a collar *d* having an angular aperture, through which, and the central opening of the arbor, it is pushed while being operated on by the revolving-cutter.

Fig. 4394.



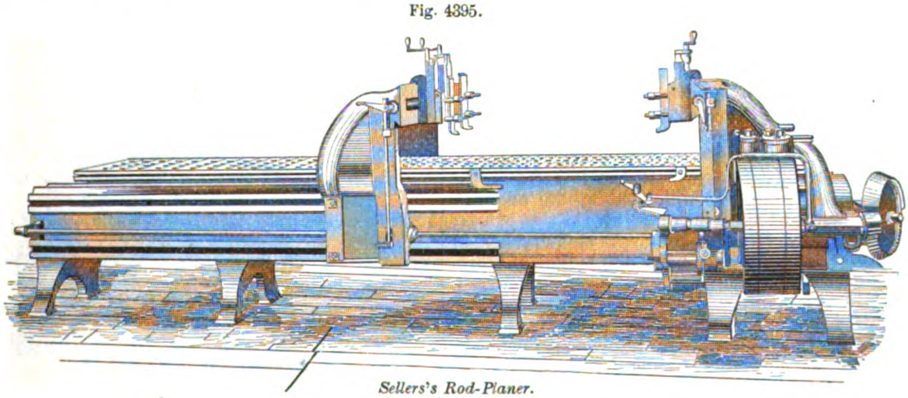
Rod, Pin, and Dowel Machine.

The collars and cutters are of different caliber, adapted to the various sizes of material used and to the required diameter of the finished rod or pin.

Rod-plan'er. A special machine-tool for planing locomotive connecting-rods, guide-bars, and similar work. It has two sets of uprights and cross-heads, with double saddle on each cross-head. The table is driven by spiral driving-gear, so arranged as to move the table at the same speed each way, and taking cut in both directions. The movable cross-head is adjustable to or from the stationary cross-head, so as to adapt the machine to varying lengths of work; say from $3\frac{1}{2}$ to 10 feet. Self-operating feed to the saddle will plane both ends of two connecting-rods at the same time. Also applicable to all kinds of stub-ends for stationary-engine work.

Rogue's Yarn. A worsted thread laid up in the middle of each strand of British dockyard rope, to prevent theft. Differently colored worsteds are used in each dockyard, in order to trace the maker of rope which proves defective.

Fig. 4395.



Sellers's Rod-Planer.

Roll. 1. (*Metal-working.*) One of the pair of cylinders between which metal is passed to draw it into bar, or to flatten it out into a sheet. See ROLLING-MILL.

The largest known to the writer is a pair of iron rolls for Sir John Brown's works at Sheffield, England. These rolls are 15 feet 6 inches in extreme length, and 3 feet in diameter, and each weighs 18 tons. They are used for rolling armor-plates.

2. (*Engraving.*) The cylindrical die in a transferring-press. See BANK-NOTE ENGRAVING. See ROLLER.

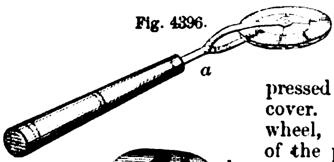
3. (*Wool-working.*) A carding of wool, delivered broadside from the cards, and somewhat compacted in the process. Rolls are prepared for hand-spinning.

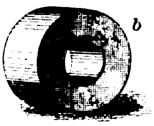
The *doffing-cylinder* of a wool-carding machine has longitudinal bands of cards with intervening spaces. The *doffing-knife* removes the fibers from these bands in *slivers* which are of the length of the doffing-cyl-

inder. They fall into the *roller-bowl*, which rolls and compacts them, bringing them into the condition of *rolls* or *cardings*, which are taken to the *slubbing-machine*.

4. (*Bookbinding.*) A tool (*a*) for hand embossing or gilding where a continuous line or pattern is to be impressed upon a book-cover. It is a brass wheel, whose edge is of the pattern desired, either in single, double, or triple line, or having fillets, interlacing, or scroll pattern engraved thereon. It is mounted in a holder and heated over gas or charcoal. The handle rests against the shoulder of the operator, and the wheel is passed along the place to be embossed. For gilding, the surface is previously spread with *glaire*, and gold-leaf is laid thereon.

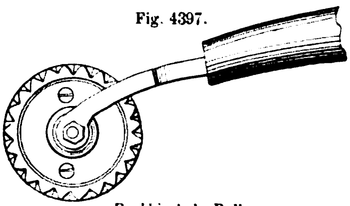
Fig. 4396.





Rolls.

Fig. 4397.



Bookbinder's Roll.

5. (*Metallurgy.*) One of a pair or series of rollers arranged in pairs, between which ores are crushed. That shown at *b* (Fig. 4396) has an interior longitudinal slot to receive the key by which it is held on the shaft.

6. (*Building.*) A strip with a rounded top laid over a roof at the ridge or at lateral joints, to raise the sheet-lead at those points.

7. (*Paper-making.*) A cylinder mounted with blades for working paper-pulp in the tub.

Roll and Fil'let. A rounded molding with a square fillet on its face.

Roll-blot'ter. One having a roller around which sheets of blotting-paper are fastened, and a handle in whose forks the ends of the roller axis are journaled.

Roll-boil'ing. (*Woolen-manufacture.*) A process for giving a luster to cloth by scalding the cloth, while tightly wound upon a roller, in a vessel of hot water or steam. (Hirst's English patent, 1830.)

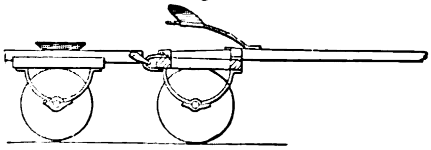
Roll-box. (*Spinning.*) In the jack-frame, the rotary can or cylinder in which the bobbin and carrier cylinder for the rovings revolve.

Roll'er. 1. (*Husbandry.*) A clod-crusher or ground-leveler. An implement of a cylindrical form to roll over arable ground to break clods, cover seed, and press in plants which are thrown out of the ground by frost.

The roller is mentioned as an implement for breaking the clods of arable ground by Googe, in his "Heresbachius," published in 1578.

The ordinary land-roller has a single cylinder

Fig. 4398.



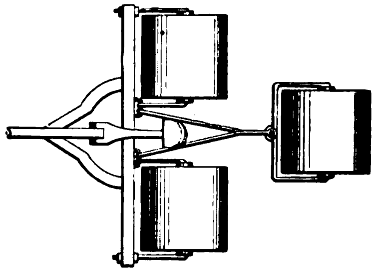
Land-Roller.

made of a trunk of a tree or of *logs* of wood upon a skeleton frame, or is a shell of iron with spokes and having sockets for an axle or gudgeons.

Fig. 4398 shows a double roller, in which the detachable tongue is confined with bands to the frame to which it is bolted. The rear rollers are adjusted and loosely attached to the elongated rear bar of the forward frame.

Fig. 4399 has three rollers on separate axles, the

Fig. 4399.



Land-Roller.

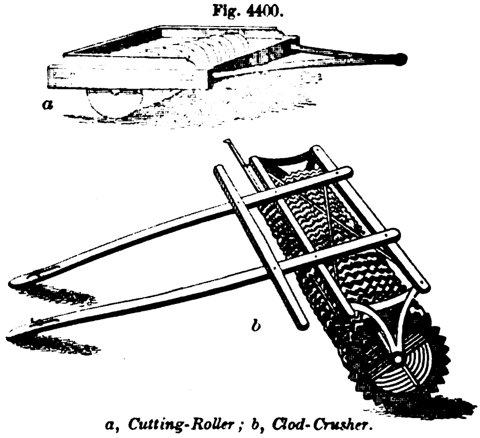
rear one trailing behind, traveling upon the ground left unrolled between the two preceding ones.

Land-rollers are also made of peculiar construction or size for specific purposes in husbandry, as the corn-roller, cane-roller.

The *roller-drill* is one having a roller following the seed-depositing share, to compact the ground upon the seed. Such a roller is a *covering*-roller.

The *cutting*-roller (*a*) has a central axis and a series of circular cutting-plates, divided by intervening collars, which maintain them at the required distance. It is used in preparing ground for tillage, cutting through sods and tangled grass and herbage to prevent choking of the plow. This is also known

Fig. 4400.



a, Cutting-Roller; b, Clod-Crusher.

as a *disk*-roller or a *flanged* roller for restoring meadows.

2. A machine for leveling roads (see ROAD-ROLLER) or for garden-walks.

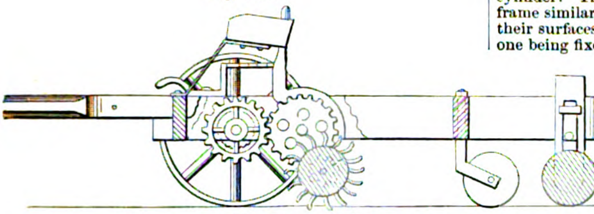
Corrugated or *toothed* rollers have been introduced into land culture, and are known as clod-crushers. This is the normal idea of a roller, but these ridged or spiky cylinders are more effective in breaking than their smooth relatives.

The *clod-crusher* (*b*) consists of a number of segments attached to an iron axle 6½ feet long. The

segments have protuberances which give the knobby character to the roller.

Fig. 4401 is a combined harrow and roller. The harrow is adjustable vertically by a lever and rotated

Fig. 4401.



Harrow and Roller.

by gearing from the axle; it is followed by a roller on the same frame.

3. (*Nautical.*) A cylindrical anti-friction bar which revolves as a hawser or rope traverses against it, and thus saves the rope from wear.

4. (*Ordnance.*) *a.* A cylinder of wood, used as a winch in mounting and dismounting guns.

b. For mechanical maneuvers in the ordnance department, rollers are used for mounting and dismounting cannon, or for transporting them to short distances.

Long and *short* rollers are circular in section, being slightly hollowed out at their midlength, the better to prevent the gun from slipping off. The *half-roller* is semicircular in section, but is similarly hollowed out on top.

5. (*Metal-working*). A circular object in a machine acting as a *carrier*, as a *cutter*, as a *die*, as an *impression-cylinder*, or as a *flattener*, *e. g.*, —

a. The *carrier* has an example in the rotating bearers on which the bed of a printing-machine traverses. It is common in other machines also, as the *drawing* rollers of spinning-machines, the *fancy* rollers and *fly* rollers of *scribbling-machines*, the *tinsel* roller of a *lace-machine*.

b. The *cutter* is shown in some forms of rotary shears and *slitting-machines*, in which the edge of a roller laps past another roller or a plate and makes a shear cut.

c. The *die* is found in the *hub* or roller die of the bank-note engraver's transferring-machine (Fig. 4403). Examples are also to be seen in many kinds of embossing-machines.

d. The impression-cylinder is found in *copperplate* printing-presses, some forms of *printing-machines*, and in *calico-printing machines*.

e. The *flattener* is found in rolling-mills, etc.

6. (*Hardware.*) A broad-faced wheel having gudgeons, and used as an anti-friction device to facilitate transportation of the object resting upon it. A *caster*. May be cited, —

Barn-door roller.	Sash-cord roller.
Chest-roller.	Trunk-roller.

7. (*Music.*) The studded barrel of the musical box or chime-ringing machine.

8. (*Stationery.*) A rolling blotter.

9. The printer's inking-cylinder. A cylinder of wood covered with a composition of glue and molasses, which is poured around it in a mold. The cylinder revolves on an iron axis as the roller runs over the face of the form.

10. Paper-making machines require cylinders of great accuracy, and their preparation involves several processes.

Abradants are dispensed with, and the required accuracy of contact is attained by the friction of the surfaces of the rollers on each other, water being plentifully supplied to prevent their heating and tearing each other.

They are first turned as truly cylindrical as possible in the lathe, and tested for parallelism by a thin copper wire applied around the circumference at various parts. The journals are turned at the same time to insure their concentricity with the cylinder. They are then mounted on their own bearings in a frame similar to that in which they are to be employed, and their surfaces carefully adjusted to each other, the bearings of one being fixed, and those of the other provided with a screw adjustment, so that they may be closed upon each other until their highest points just touch. They are then examined to see how they correspond to each other. Having been turned in the same lathe, their errors are usually alike, that is, they are either both convex or both concave; long rollers generally have the latter defect, in consequence of the middle part of the slide being more worn from turning short pieces of work. When there is a considerable want of correspondence between the two it is reduced by grinding each separately with a lead grinder mounted on the end of a long lever and supplied with emery.

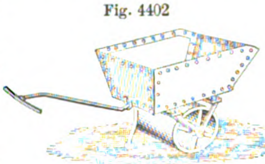
When reduced nearly to correspondence with each other, they are adjusted so as to revolve in contact, and the face of one is marked with chalk lines at intervals of a few inches; the manner of transferrence of these from one to the other indicates which parts do and which do not come in contact. The projecting parts are then farther ground away. When all the lines are transferred with considerable regularity, showing that the two surfaces nearly fit each other, they are adjusted by bringing their highest points into contact, and are then, by belt and pulley connections, caused to revolve in opposite directions and at different speeds, a constant stream of water being meanwhile directed upon them. By this means fresh points on each are continually brought in contact with each other, causing an equal and uniform abrasion, and gradually reducing both to a truly cylindrical surface. As the most projecting parts are gradually brought into correspondence, the two are pressed together by the adjusting screws, bringing a greater proportion of their surfaces into contact, and the operation is thus continued until both are gradually reduced to their true form, care being taken to avoid too great friction between them, which might heat and tear the surfaces. The process is tedious, and requires several days for its completion. See also Fig. 4405.

Sometimes the rollers are ground under a pressure equal to that which they will have to sustain when at work, in order to ensure their not bending when actually required to perform their duty in the machine. In this case the two are driven in the same direction, but with slightly differing velocities.

11. (*Saddlery.*) The broad, padded surcingle used as a girth to hold a heavy blanket in its proper position, generally made of twilled web with leather billets and chapes.

Roll'er-bar'row. A barrow mounted on a wide roller so as to cause no injury to the grass, as the wheelbarrow does, by cutting into the turf with its narrow wheel.

Fig. 4402

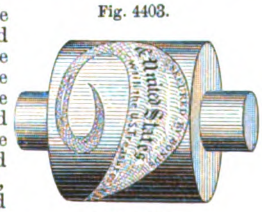


Roller-Barrow.

Roll'er-bowl. (*Woolen-manufacture.*) A device at the delivery end of a wool-carding machine, for rolling the *slivers* detached by the *doffing-knife* from the longitudinal band-cards of the *doffing-cylinder*. The rolling compacts the *slivers* into *cardings* or *rolls*, which are delivered upon an apron, and are removed to the *slubbing-machine*, where they are joined endwise and receive a slight twist.

Roll'er-die. A die of cylindrical form, used in transferring steel-plate engravings for bank-note printing, and also the patterns to the rolls used in calico-printing. The design is first engraved on a plate of soft steel, which is then hardened and subjected, in con-

Fig. 4403.



Roller-Die.

junction with the die of soft steel, to the action of a powerful press, by which the intaglio lines of the plate are transferred in cameo to the die; this is afterward hardened, and serves to transfer the design to a plate, a roller, or to another die.

Roll'er-gin. 1. One in which the cotton is drawn away from the seed by pinching-rollers, in contradistinction to the *saw-gin*. See COTTON-GIN.

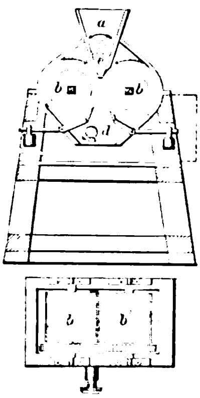
2. (*Hoisting.*) One provided with a roller on which the rope winds, and with a ratchet and pawl to sustain the weight.

Roll'er-lift. (*Printing.*) A small cam to raise the rollers from the ink surface in a power-press.

Roll'er-lock. (*Printing.*) A frame carrying adjustable roller-journals.

Roll'er-mill. A machine for bruising flaxseed, before grinding under edge-stones and pressing. The seeds are placed in the hopper *a*, and are fed downward to the crushing-rollers *b b'* by a small roller *e* within the hopper. The rollers *b b'* are geared together so as to rotate in opposite directions, and are turned by a hand crank on the shaft *d*, which carries a fly-wheel at its other extremity, and also a pulley, which rotates the feed-roll *c*. The crushed seeds fall through a slit into a box beneath the machine.

Fig. 4404.



Roller-Mill.

Roll'er-mold. (*Printing.*) A mold in which composition inking-rollers are cast.

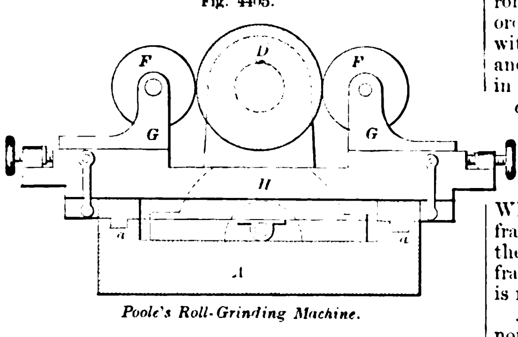
Roll'er-stock. (*Printing.*) The frame upon which composition rollers are cast. It has usually a journal at each end.

Rol'ley. (*Mining.*) A large truck in a coal-mine, holding two corves as they arrive on the *trams* from the workings. A number of *rolleys* are coupled together and hauled by a horse to the bottom of the engine-shaft. A *trolly* is a small two-wheeled truck used in a rolling-mill to wheel the balls of puddled iron to the squeezer.

Rol'ley-way. (*Mining.*) A tramway in a mine.

Roll-grind'ing Ma-chine'. A machine for accurately grinding rolls for the finer kinds of sheet-metal rolling, and more especially for calender rolls. Poole's machine, patented July 8, 1868, has one or more pairs of cutting or grinding tools upon a frame which is free to move laterally or transversely to the object which is being turned or ground, the tools constituting a pair being capable of adjustment thereon, in relation to one another, and dependent for their movements to and from the surface of the object placed between them to be turned or ground by their contact with the surface or surfaces of the object at opposite points thereof.

Fig. 4405.



Poole's Roll-Grinding Machine.

The view is a transverse section through the roll *D*, bed *A*, and ways *a*, showing the grinders *F*, rests *G*, and slide-bed *H* in end elevation.

See also his patents, January 18, 1870; June 21, 1870; August 20, 1872. In the June 21, 1870, patent, the surface is reduced by devices moving parallel to a vertical plane passing through the axis of the roll, but inclined to a plane passing horizontally through the said axis. This obliquity is obtained by the depression of one of the bearings. The effect is to give a diminished waist to the roller, the grinding line being a curve and the roll spindle-shaped. See also description under ROLLER, 10 (previous page).

Elliott, December 15, 1874, has an arrangement of three grinding wheels presented at an angular relation of 120° to the roll to be ground, the grinders being journaled in a frame, which is free to move in all directions in a plane transverse to the cylinder placed between them, their movement depending on the surface to be ground. To prevent undue pressure of the upper wheel upon the surface, the weight of the frame is counterbalanced by a lever and counterpoise.

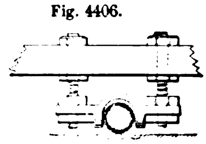
Roll'ing. 1. (*Metal-working.*) The process of drawing out or flattening metal by passing between rollers. See ROLLING-MILL.

2. (*Bookbinding.*) The process of flattening the pack of gathered signatures by hammering or passing through the rolling-press.

Roll'ing-bar'rel. (*Gunpowder.*) A barrel in which the ingredients for making gunpowder are pulverized. It has an axis at each end, on which it rotates, and a door for the introduction and removal of materials. That used for charcoal is of cast-iron, having a series of interior ledges, and that for niter and sulphur of leather stretched on a wooden frame. The material, together with twice its weight of bronze balls, is placed in the barrel, which is rotated from one to eight hours, according to circumstances.

Roll'ing-bridge. *a.* A railway *drawbridge* made to move laterally upon a carriage until it has passed the junction of the line of rails, and thence to pass inward, so as to leave the water-way clear.

Fig. 4406.



Rolling-Bridge.

b. Another form of the rolling-bridge, intended for ordinary roadways, is merely withdrawn on the main track, and when restored is supported by struts which rest in set-offs in the wall of the abutment.

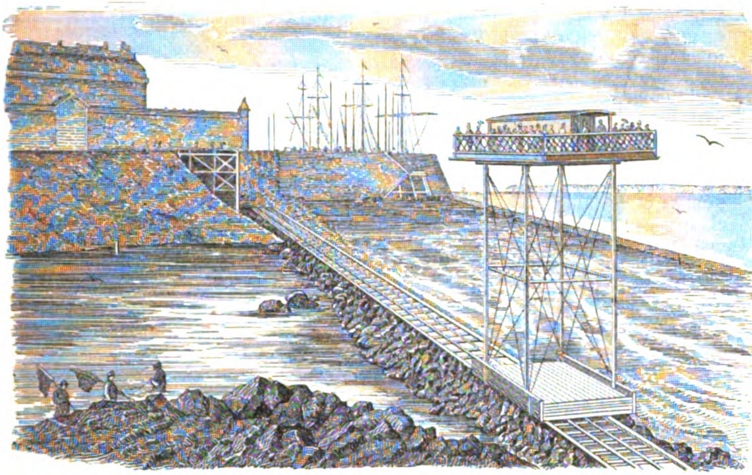
c. Or the rolling-bridge may have a strong frame supported by wheels upon a line of rails and an overhanging portion sufficient to span the water-way; or one half of the water-way, if it be met by a similar half-bridge from the other side. When closed by being rolled forward, the rolling frame leaves a gap between its platform and that of the approach. This gap is filled by another rolling frame that moves sideways. The latter rolling frame is rolled out of the way before opening the bridge.

Another rolling-bridge traverses in an arc on cannon-balls. See SWING-BRIDGE.

d. Figs. 4407 and 4408 illustrate the bridge connecting the towns of St. Malo and St. Servan, in

France, on an estuary into which the river Ronce discharges. The rise of the tide is here very great, so that while at low tide the bed of the estuary might be crossed, at high tide passengers were compelled to make a wide circuit. To obviate this, the arrangement shown, consisting of a platform having accommodation for horses and vehicles, supported on pillars, and having wheels running upon rails laid on the bed of the estuary, was designed by M. Leroyer.

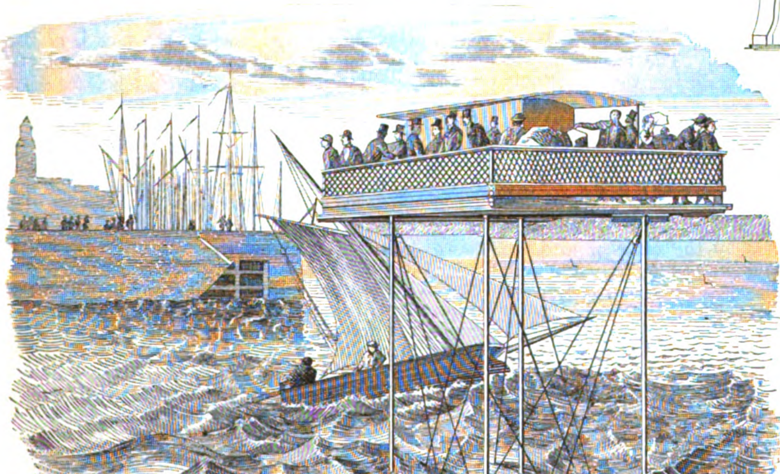
Fig 4407



Rolling-Bridge of St. Malo, France (Tide out).

e. The rolling-bridge for the assault of fortifications is a platform on wheels or rollers, driven up the glacis and intended to span the ditch, to admit the assaulting column into the works.

Fig. 4408.

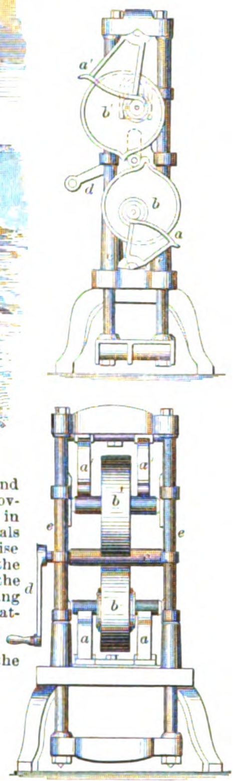


Rolling-Bridge of St. Malo (Tide in).

Roll′ing-cam Press. A press operated by a roller revolving between cam-wheels. This movement was invented by Dick, about 1848.

In the figure, *a a′* are the sectors, the lower one of which has a bearing in a groove in the lower fixed bed, and the upper in a groove in the movable bed above; their faces are in contact with the eccentric journals of the cam-wheels *b b′*, which rise and fall between guides on the standards *e*, and between which the roller *c* is interposed; on depressing the lever *d* to which this roller is attached, the sectors are caused to rotate into the position shown, bringing the longer axes of the cams into perpendicular position, thereby raising the upper bed.

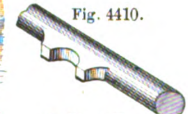
Fig. 4409.



Dick's Anti-Friction Press.

Roll′ing-chocks. (*Nautical.*) Jaws on a yard to steady it against the mast when a ship rolls.

Fig. 4410.

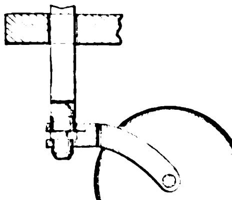


Rolling-Chock.

Roll′ing-col′ter. A sharp-edged wheel which is attached to the beam of a plow, and cuts downwardly through the grass and soil to divide the furrow-slice from the land.

Roll′ing-frame. (*Dyeing.*) The frame with

Fig 4411.



Rolling-Colter.

rollers by which cloth is drawn through the dye-beck. *Gallopers.*

Roll'ing-hitch. (*Nautical.*) Passing a rope round a spar, log, or cask, so that a pull upon the rope will roll the same.

Not to be confounded with the PARBUCKLE, which see.

Roll'ing Met'als. (*Metal-working.*) The process of forming metal into rods, bars, or plates by drawing it between cylindrical rollers, which are either plane or grooved to suit the shape to be imparted.

The grooved rolls are the invention of Henry Cort, in 1783. Iron, steel, and copper are rolled while red-hot, but most other metals and alloys are rolled cold; in most instances requiring frequent annealing during the process of their gradual reduction to the required dimensions. With the exception of iron and steel, the metal is cast into slabs preparatory to being drawn into sheets.

In some instances, as in the case of plating silver with gold, one metal is united with another by rolling. See ROLLING-MILL.

Roll'ing-mill. In the rolling-mill, the iron, which is heated and balled in the puddling-furnace, is made into bars or sheets. The rolls are journaled in pairs in metallic boxes in the iron standards or cheeks, and are capable of being set toward or from each other by means of set-screws. The grooves in the rolls are so made as to be coactive in giving the required form to the heated iron passing between them. Sometimes, as in the larger description of rolls, the grooves are counterparts, each forming one half of the bar of iron; and sometimes a ridge or rib on one roll projects into a groove in the roll beneath and forms one side only of the bar. The face of each roll has a series of grooves gradually decreasing in size toward one end. The iron is passed through each in succession, being thus gradually reduced in size and increased in length. Each time through is known as a *pass*, — a term which is also applied to the groove in a roll or the opposite groove, forming the space through which the bar passes.

The ball of iron from the squeezer is dragged along a track of iron plates on the floor of the mill and jerked on to a platform in front of the train of rollers. It is here directed by the operator into the larger of the grooves, is nipped by the rolls and drawn through. If the mass be large it is received on the other side of the rolls by two men, one of whom raises it by a bar which is suspended by a chain, the other man seizing the end of the bar with his tongs, and directing it so as to rest upon the upper surface of the upper roll which carries it over and allows it to drop again on to the platform. The head operator then again seizes it with his tongs, and directs its end into the next of the series of grooves, when the operation is repeated again and again till the required size is reached, and the bar is dragged off and laid on a floor to cool.

The operation of rolling has the effect of compressing the iron, knitting its fibers together, and drawing them out so as to assume a direction longitudinal of the bar, some extraneous matters being also removed in the operation.

In the year 1783, Henry Cort, of Gosport, England, received an English patent for the rolling of iron, as a substitute for hammering. During the following year he patented the puddling process.

Cort is the greatest name on record in the "History of Iron."

Plain rolls for reducing metal were in use before Cort's invention, and are mentioned in Dr. Johnson's Tour, 1774: —

"We then saw a brass works, where the *lapis calaminaris* is gathered, broken, washed from the earth, and the lead (though how the lead was separated I did not see) then calcined, afterward ground fine and then mixed by fire with copper. We saw several strong fires with melting-pots, but the construction of the fireplaces I did not learn. At a copper works, which receives its pigs of copper, I think, from Warrington, we saw a plate of copper put hot between steel rollers and spread thin. I know not whether the upper roller was set to a certain distance, as I suppose, or acted only by its weight. At an iron works I saw round bars formed by a notched hammer and anvil. There I saw a bar of about half an inch or more square, cut with shears worked by water, and then beaten hot into a thinner bar. The hammers, all worked as they were by water, acting upon small bodies, moved very quick, as quick as by the hand. I then saw wire drawn, and gave a shilling. I have enlarged my notions, though not being able to see the movements, and having not time to peep closely, I know less than I might."

Cort was the first to use *grooved* rolls, for which, in combination with other improvements, a patent was granted him. The first mention that we have of the use of rolls for reducing iron is to be found in "Coxe's Tour in Monmouthshire," where they are said to have been invented by John Hanbury, and used for rolling plates. This is mentioned in a note to chapter second, by Scrivenor, "On the Iron Trade."

Rolling-mills are of several kinds, according to the condition or the destination of the iron.

The first set is called the *forge-train, muck-train, blooming-mill*, or *puddle-bar train*.

The second is called the *merchant-bar train, plate-mill, rail-mill*, or *wire-mill*.

The first pair of each set is the *roughing down*, and the second pair is the *finishing*.

When the iron is to be re-rolled, as for nail-plates for instance, the bars are cut into plates of equal length and built in piles, into a re-heating furnace, whence they are taken and rolled in the nail-plate train, assuming a width equal to the length of the plates from which the nails are to be cut. See BAR-SHEARS.

For special and important work, such as *breaking down* (rolling to a gage) ingots of gold or silver for coin, a register has been contrived by Franklin Peale, late chief coiner of the United States Mint, Philadelphia. It has a hand and index, and the crank on the hand arbor is the means of giving the *set* to the rolls, while the hand indicates their relative distance. See REGISTER.

In the British and French departments at the French Exposition were exhibited armor-plates for ships originally rolled from 20 to 30 feet in length, from 3 to 6 feet in breadth, and from 8 to 13 inches in thickness.

An armor-plate was rolled at the "Atlas Works," Sheffield, England, in 1862, 20 × 4 feet, and a thickness of 15 inches. The operation was thus described by a spectator: —

The plate, when laid in the furnace, rests upon little stacks of fire-bricks, so that the flame and heat play equally round it, till all is glowing white and the successive layers have settled down into one dense mass. At a signal from the furnace-man, the bands of workmen, to the number of about 60, arranged themselves on each side of the furnace, as near to it as they could bear the heat. Then the doors were opened to their fullest, and in the midst of the great light lay a mass even whiter than the rest. To this some half a dozen men drew near. They were all attired in thin steel leggings, aprons of steel, and a thin curtain of steel wire-work dropping over their faces like a large, long visor. All the rest of their bodies were muffled in thick, wet sacking. Thus protected they managed, with the aid of a gigantic pair of forceps slung from a crane above, to

work, as it were, amid the flames for a few seconds, and to nip the huge plate with the forceps. The signal was then given, and the whole mass of iron, fizzing, sparkling, and shooting out jets of lambent flame, was, by the main force of chains attached to the steam rollers, drawn forth from the furnace on to a long wrought-iron car. The heat and light which it then diffused were almost unbearable in any part of the huge mill, but the men seemed to vie with each other to approach and detach the colossal pinchers which had drawn the iron forth. More than a dozen attempts were made on this occasion before this was effected, and more than a dozen of the best and most skillful workmen were driven back one after another by the tremendous heat and glare. At last all was made clear. The forceps, then red-hot from their grip of the plate, were drawn away, the chains cleared from the rollers, and, with a great hurrah, the other workmen seized the chains attached to the iron truck and drew it to the incline by main force, where it was left by its own weight to run into the jaws of the rolling-mill. It was then *sauve qui peut* among the workmen, who rushed for shelter in all directions as the mass was nipped between the rollers and wound rapidly in amid quick reports like those of dull musketry, as the melted iron was squeezed by the tremendous pressure out of the mass, and flew out in jets of liquid fire on all sides. The turning of the rollers crushes the plate through to the other side, where it rests for a minute on a wrought-iron truck similar to that on which it was brought from the furnace. The action of the rollers is then reversed after they have been, by the action of screw levers, brought closer together by about an inch. These again nip the plate and drag it back in an opposite direction, and again and again does the mass go forward and backward, each time passing between a smaller space between the rollers, till the whole of the huge thickness is reduced to a compact mass 15 inches thick in less than a quarter of an hour. During every stage of the process, quantities of fine sand are thrown upon the plate, and this literally takes fire as it touches the flaming surface, and covers it as it melts with a coat of silica, or with a glaze like that of earthenware. After every discharge of sand, and these go on almost incessantly, buckets of water are thrown upon the plate and explode in clouds of scalding steam; and when these are partly dissipated, men rush forward and with wet besoms with handles 20 feet long sweep off whatever little scraps of oxidation may have taken place. Thus, every time the plate passes through the mill the sand is scattered, the water thrown, and the surface swept, and at every roll the chief roller of the establishment runs forward, and, under the shelter of wet cloths, measures with a gage its thickness from end to end. The required dimensions were obtained by less than a quarter of an hour's rolling, and a plate 15 inches thick, the product of the labor of nearly 200 men and of the consumption of nearly 250 tons of coal, was shot out by the rolling-mills and left to cool. When this had been effected, two large rollers of iron, each weighing 15 tons, were placed upon it by the cranes, and moved slowly backward and forward; and eventually, as the plate cooled, were left upon its ends to keep the whole perfectly level. Nothing farther now remained in order to complete it as the finest specimen of armor-plate manufacture ever attempted but to plane off its rough ends and edges. The flat surfaces on either side, which form what is called the skin of the plate, are never interfered with, for the action of the steel rollers leaves them literally almost as smooth as plate-glass.

Several devices for making the rolling of bars more continuous in point of time have been suggested, and one of them used, the *three-high train*, in which the iron is passed between the upper and middle roll, then back between the middle and lower one, and so on. A series of six rolls in the same vertical series has been proposed, so that the bar might have five passages without much loss of time.

The other proposition was to set the rolls in parallel rows, so that the iron would pass from one set to another, preserving the same line of motion through as many as might be necessary to produce the grade of bar required.

The *three-high* train has three rolls in vertical order, affording two sets of *passes*, one between the upper and middle roller, the other set between the middle and the lower roller, as seen at Figs. 4412, 4416. It is designed to enable the metal to be passed in each direction, rolling at each passage. Fig. 4412 shows the three-high feature, and also the mode of bringing a bar gradually to form by sending it through passes of a shape gradually approximating that required. The triple flange is gradually educed, as may be seen by tracing the shape from the square bar in Fig. 1, through that series, and then through the series in Fig. 2.

Reversing-mills are generally employed in Great Britain in preference to three-high rolls. In France, three-high trains have been in use for rolling girders since the year 1849, and everywhere upon the Continent of Europe the principle seems to be perfectly well understood; but the reversing-mill is generally preferred.

Fig. 4413 is an arrangement of rolls for rolling taper tubes or rods. Each of a pair of rolls has a spiral groove of variable depth, and of half-round section, turned on it. The groove in one roll is a right-handed, and that in the other a left-handed spiral, as shown in the engraving; and when the rolls are placed together and geared, so as to revolve in union, the grooves form a series of eyes, which, as the rolls revolve, appear to move laterally and gradually decrease in size. Thus, if a bar or tapered strip of iron, bent so as to approximately form a tube, be introduced between the rolls at that end where the grooves are largest and deepest, it will be gradually shifted toward the other end of the rolls as it passes between the latter, and will thus be rolled taper.

Fig. 4412.

Fig. 1.

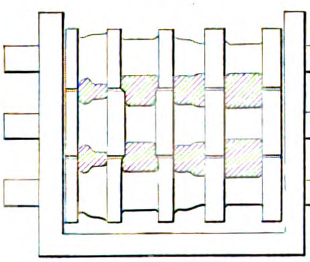


Fig. 2.

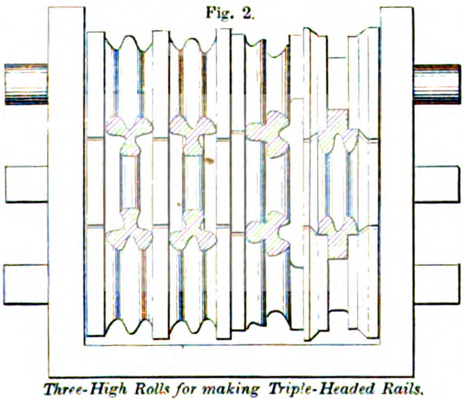
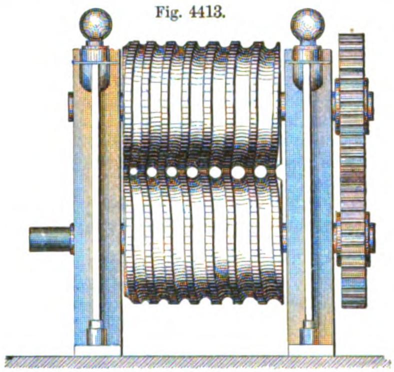


Three-High Rolls for making Triple-Headed Rails.

Fig. 4413.



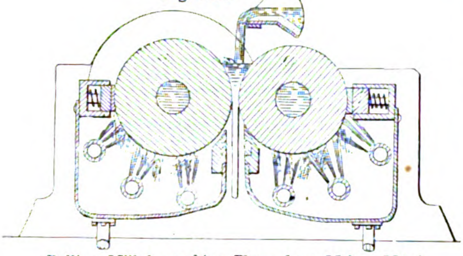
Spiral-Groove Rolls.

A mill adapted to sheet-iron or sheet-lead has a platform like that of a wood-planing machine, except that it has rollers to enable the sheet-lead to travel with less friction, and thus prevent buckling.

Fig. 4414 shows Bessemer's plan, intended to make the plates or sheets of metal directly from fluid iron or steel as it comes from the furnace. The metal is allowed to flow from the ladle or furnace into the space between two rollers, the said rollers being provided with openings in their centers for the circulation of water. The external surfaces of the rollers are cooled by jets of water.

The same plan was attempted many years ago by Chance of Birmingham, England, for making plate-glass. It was abandoned.

Fig. 4414.



Rolling-Mill for making Plates from Molten Metal.

Owens's (Rotherham, England) method of making tires, etc., consists in bending a rod or rods of iron around a block, so as to form a coil having about ½ the diameter and 2½ or 3 times the depth of the finished tire.

This is brought in a furnace to a full welding heat, and transferred to a die on the anvil of a steam-hammer, whose piston carries a similar die. By these it is compacted into a homogeneous mass, which is expanded to the proper diameter between two rollers, the upper one of which may be lifted to any required distance from the lower by means of a small hydraulic press. A larger hydraulic press is employed to force the two rolls together in proportion as the diameter of the tire is enlarged. Other rolls, adjustable by hand or automatically, serve as guides to impart a true circular form to the blank.

Different plans have been adopted by others for preparing tire-blanks for the rolling-machine. Krupp's method consists in forging a bar of steel into the form of a compressed hoop, which is then cut down the middle, opened out, and afterward finished in the rollers.

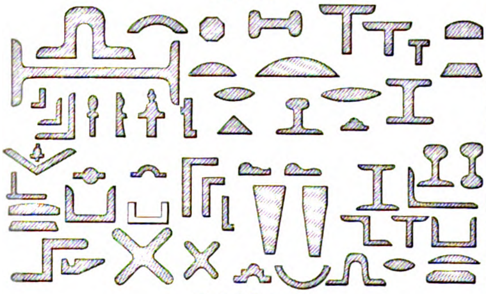
Bessemer forms an ingot of steel and cuts out the central part, so that the annulus left may be enlarged by the rolls.

Naylor and Vickers, of Sheffield, prepare the circular steel blanks by casting.

An exemplification of the nicety to which the rolling of mètal can be carried is shown in the process known as *nature-printing*. A piece of delicate lace is placed on a small sheet of metallic tin, which is then passed once between a pair of steel rolls, the surfaces of the latter being brought in close approximation by means of actuating screws. The pattern of the lace is reproduced with the utmost fidelity on the tin. See NATURE-PRINTING.

Fig. 4415 exhibits some of the many forms which may be imparted to malleable iron by suitable grooves

Fig. 4415



Rolled Irons.

in the rolls composing the train. Each is made by one continuous operation. See also Figs. 2698 and 2699.

Pig-iron is the crude metal from the smelting-furnace, cast into bars or pigs.

The term bar-iron is restricted to refined or wrought iron. The bars are *flat*, *square*, *round*, *oval*, *half oval*, or *half round*; *horseshoe* is a fine quality of flat bar-iron; *nail-rod* iron, small square iron of fine quality. *Heavy bands*, *light bands*, and *hoop iron* are thin and comparatively wide bars. *Railroad iron* includes flat and T rails, axles, fish-plates, bolts, chairs, and spikes. Building-iron embraces *beams*, *deck-beams*, *channel-bars*, *T-iron*, and fittings. *Angle-iron* is known as *equal-sided*, *unequal-sided*, *obtuse*, *star*, *sash*, etc. Sheet-iron is divided into *common*, *charcoal*, *galvanized*, and *planished*. *Russia sheet* is a fine quality of planished charcoal iron. See RUSSIA IRON.

Roofing-iron is corrugated or crimped, and is either *galvanized* or *black*; it is numbered according to thickness. *Tank* and *fire-bed iron* are similarly classified. Boiler-plate iron is thicker than the above, that common in the trade varying from $^3/_{16}$ to $^5/_8$ inch.

Weights of Wrought-Iron, Steel, Copper, and Brass Plates soft rolled. (HASWELL.)

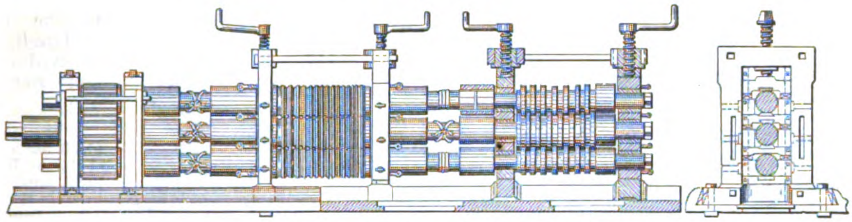
Roll'ing-mill Train. The system of grooved rollers by which iron bars are gradually drawn down from balls or blooms.

The rolls in Fig. 4416 are arranged in series of three each, each having grooves corresponding to those in the roller above or below it. The rough bar is drawn through the largest first and then through the next smaller, and so on in succession to the smallest, by which the finished bar is completed.

The grooves are of such sections as to form square, round, T, or other angle iron, and are known as *passes*.

Fig. 4417, *a a'* and *b b'* are two-high grooved rolls made of chilled cast-iron. The former are designed for rolling flat and the latter square bars. Nuts *c c'* regulate the distance of the rolls from each other, and the tubes *d d'* serve to convey water for cooling

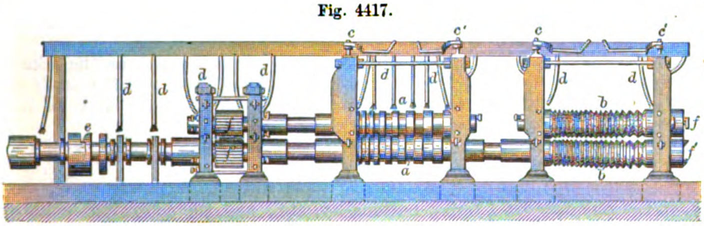
Fig. 4416



Three-High Rolling-Mill Train for Merchant Bar.

the machinery. By means of the coupling *e*, the rolls are put in or out of gear with the motor which, through the medium of the gears *f f'*, causes the upper and lower rolls to rotate in opposite directions.

Fig. 4417.



Rolling-Mill Train.

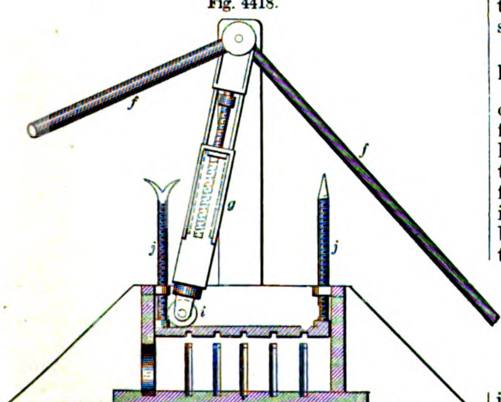
Roll'ing-pen'du-lum. A cylinder caused to oscillate in small excursions on a horizontal plane. It was designed as a time-measurer, but appears to have answered no practical purpose.

Roll'ing-pin. (*Domestic.*) A wooden cylinder having a projecting handle at each end, by which dough is rolled into sheets suitable for pie-crust, etc.

Roll'ing-press. 1. (*Printing.*) The copperplate printing-press in which the plate and bed pass beneath a roller by means of rotation applied to the latter. A certain degree of elasticity is afforded by a sheet or two of paper between the plate and the bed and a number of blankets on the roller. See COPPERPLATE PRINTING-PRESS.

2. (*Bookbinding.*) A machine for smoothing and condensing the leaves of books as a substitute for hammering. It usually consists of a pair of iron rollers turned by a crank, and having a table at each side for the feeding and delivery of the packets between plates.

Fig. 4418.



Rolling-Pressure Baling-Press.

Roll'ing-press'ure Press. A baling-press in which the follower is depressed by the pressure of the roller *i* at the end of the extension-bar *g*, which traverses to and fro, as rocked by the levers *f f*. The downward position of the follower is sustained by screws *j j*.

Roll'ing-stock. (*Railway.*) The cars of all descriptions which traverse the rails of a railway. See LOCOMOTIVE; RAILWAY-CAR. See also list and general index under RAILWAY ENGINEERING and PLANT.

The return of railway rolling-stock, as given in "Poor's Manual" for 1874, 1875, on the roads of the United States and Canada, is as follows: —

Passenger-cars of all classes	2,990
Baggage, mail, and express cars	4,157
Box, merchandise, and house cars	87,009
Platform, gondola, and flat cars	52,198
Stock-cars	14,222
Coal-cars (number of wheels not stated)	66,887
Four-wheel cars (mostly coal)	37,892
Caboose-cars	1,549
Oil-cars	3,154
Ore-cars	2,102
Lumber-cars	193
Freight-cars not classified	94,694
Total	373,959
Locomotive engines	14,939

Deducting from these aggregates 774 engines and 13,980 cars of all classes, as returned by the Canada roads, leaves for the roads in the United States a total of 14,165 engines and 359,979 cars, exclusive of what are denominated service-cars, and exclusive of narrow-gage cars.

Roll'ing-tack'le. (*Nautical.*) A tackle which keeps a yard over to leeward when the ship rolls to windward. It is hooked to the weather quarter of the yard, and to a lashing on the mast near the slings.

Roll-joint. A sheet-metal joint in which the parts are rolled upon one another and pressed tight.

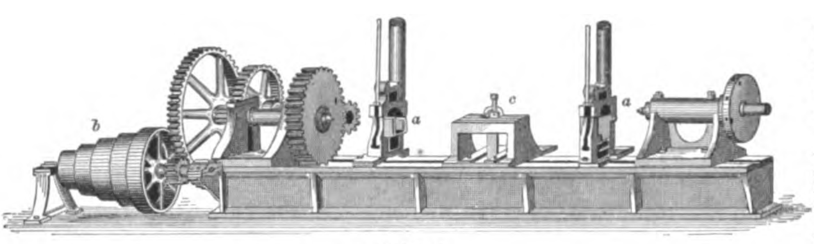
Roll-lathe. (*Machinery.*) A lathe for turning off rolls for rolling-mills, calendering-machines, and for other purposes. In Fig. 4419, it is shown as having a pair of rests *a a*, in which the journals of the heavy iron roll rest, so as to take the weight from off the centers. The mandrel of the head-stock is driven by the usual slow-speed gearing from the band-pulley *b*. *c* is the slide-rest which carries the tool.

Roll-mold'ing. (*Architecture.*) A molding used in Gothic architecture, the upper half of which extends over the lower half, as if it were formed of a thick substance rolled up.

Rom'al. (*Fabric.*) An Indian silk.

Ro'man Bal'ance. An instrument for weighing, consisting of a lever having arms of unequal weight on the respective sides of its point of suspen-

Fig 4419.



Roll-Lathe.

sion, and a *bob* which traverses the longer, graduated limb. See STEELYARD.

Ro'man-can'dle. (*Pyrotechny.*) *a.* A tube (an old gun-barrel sawn off short is best) is partially filled with alternating perforated stars and small charges of gunpowder. Fire communicated to the upper end ignites the charges successively, which throw out the stars until all are discharged.

b. A similar firework in paper tube.

Ro'man-cem'ent. A kind of cement originated about 1812, by Parker, of London. The term "Roman" is a misnomer. Septaria — nodules of indurated clay with lime and iron — are burned, ground, and mixed into a mortar with lime and sand. It hardens very quickly, and is very durable. See POZZUOLANA; HYDRAULIC CEMENT; CEMENT.

Ron'dle. (*Metal-working.*) A round plate or disk. The term is applied to the crust or scale which forms upon the surface of molten metal in cooling, and which is removed from the crucible or cistern from time to time as it congeals, in order to obtain the metal in a form suitable for farther treatment instead of in a solid mass. Spelled also *rondelle.* Copper thus treated is known as *rose copper*, from its red color, and the disks are known as *rosettes;* they are again refined to restore or acquire malleability by the reduction of the suboxide of copper.

Ron-geant' Style. A mode of calico-printing. See DISCHARGE-STYLE.

Rood-loft. (*Architecture.*) A gallery over the entrance to the choir in medieval churches, at the front of which a large *rood* or crucifix was usually placed.

Roof. 1. (*Architecture.*) The uppermost member of a building. It consists of the *framework* and the *covering.*

The following table shows the structure, flattest ordinary slope, and weight in pounds per square foot of several kinds of roofs: —

Material.	Flattest ordinary Slope.	Weight in lbs. per sq. foot.
Sheet-copper, .022 inch thick..	4°	1.00
Sheet-lead	4°	7.00
Sheet-zinc (average)	4°	1.50
Sheet-iron, $\frac{1}{16}$ inch, plain......	4°	3.00
Sheet-iron, $\frac{1}{16}$ inch, corrugated	4°	3.40
Cast-iron plates, $\frac{3}{8}$ inch........	4°	15.00
Slates	30° to 22½°	5.00 to 11.20
Tiles	30° to 22½°	6.50 to 17.80
Boarding, $\frac{3}{4}$ inch thick.........	22½°	2.50
Thatch	45°	6.50
For the extra timbering of slated and tiled roofs, add........		6.00
For the pressure of the wind, add		40.00

The *span* is the width between supports.

The *rise* is the hight in the center above the level of the supports.

The *pitch* is the slope of the rafters. It is expressed in many ways: —

1. The *angle* which it forms with the horizontal; expressed in degrees.

2. By a name which indicates to the expert conformity with received models and standards, as, —

a. Grecian pitch, which has an angle of 12° to 16°, or a hight equal to $\frac{1}{9}$ to $\frac{1}{7}$ of the span.

b. Roman pitch, which has an angle of 23° or 24°; or a hight equal to $\frac{1}{5}$ to $\frac{2}{9}$ of the span.

c. Gothic pitch, which is equilateral, the rafters being equal to the span.

d. Elizabethan pitch, the rafters longer than the span.

3. By the hight in parts of the span, as *quarter*, *fifth*, *whole*, etc.

4. By the length of the rafters in parts of the span, as *two thirds*, *three quarters*, etc.

Pitch varies between the *knife-edge*, as the Elizabethan is sometimes called, and the flat *leads* in which the slope is only sufficient to carry off the water.

Common pitch, so called, has a rafter $\frac{3}{4}$ of the span. See PITCH.

The names of roofs indicate form, structure, material, nationality, etc., and the following includes the principal varieties. Some of the names are synonyms: —

Compass-roof.	Imperial roof.
Composed roof.	Killessed roof.
Crib-roof.	King-post roof.
Crown-plate roof.	Lean-to roof.
Curb-roof.	Mansard-roof.
False roof.	Pavilion-roof.
Flat roof.	Pent-roof.
French roof.	Platform-roof.
Gabled roof.	Pointed roof.
Gothic roof.	Queen-post roof.
Gravel roof.	Ridged roof.
Grecian roof.	Saddle-roof.
Ground-roof.	Shed-roof.
Half-hip roof.	Span-roof.
High roof.	Tin roof.
Hip-roof.	Truncated roof.

The early Gothic architects endeavored, as far as possible, to dispense with wood by the employment of stone vaulting, and it is not until the reign of Edward III., 1327, that timber-framed roofs became common in large constructions. They began to be common in churches about the year 1400, and from that time to the present, wood, though now to some extent supplanted by iron, has maintained a preëminence as a roofing material.

The simplest form of roof (1) consists merely of inclined rafters *a b*, butting at their upper ends; to keep their lower ends in place, however, a fixed bearing of some kind is necessary. For this purpose the tie-beam *c* (2) is introduced, into which the lower ends of the rafters are mortised.

To stiffen the truss thus formed, and to support the middle of the tie-beam so as to prevent its sagging at the center, the king-post *d* (3) is added; this is formed from a large piece of timber, partially cut away for the greater portion of its length, so as to leave a projection on either side at top forming the *joggles*, against whose under surfaces the rafters rest, and two shoulders toward the bottom against which struts *e* (4) supporting the rafters bear.

The lower end of the king-post may be mortised into the tie-beam, but is preferably connected with it by an iron strap passing round the tie-beam and secured to the post. The ends of the tie-beam are immediately supported by the walls of the building. Thus it will be seen that the tie-beam supports the rafters, and keeps their feet from spreading apart; that the rafters support the king-post and through it the center of the tie-beam; and that the king-post, in its turn, through the medium of the struts, helps to sustain the rafters.

5, 6 are two forms of flat-topped roof. In the first, the tie-beam is supported at two points by the side posts *f f*; these depend from the truss-beam *g*, against which the upper ends of the rafters rest. This construction is not so stable as the following, in which the lower ends of the side posts are united by straps which also serve to connect them with the tie-beam.

7 is a queen-post roof. The rafters are sustained at dif-

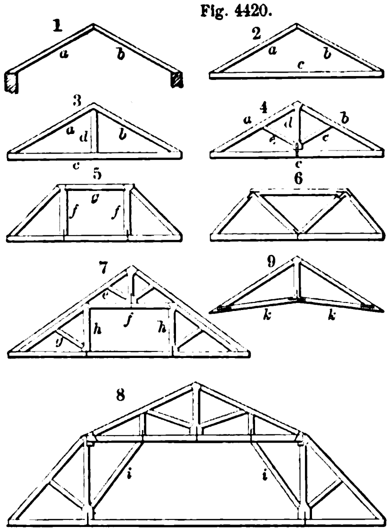
ferent points by the struts *e*, straining-beam *f*, and braces *g*; the straining-beam depends from the central post against which the ends of the rafters abut, and the queen-posts *h h* support the tie-beam on either side of the center, as in the first form of flat-topped roof. See also QUEEN-POST ROOF.

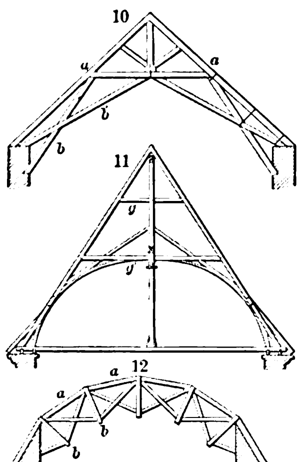
It is not usual, except in the smallest and cheapest constructions, to fasten the boarding to which the roof covering, whether shingles, tiles, or slates, is nailed, directly on the main rafters.

These are coupled at intervals of 8 or 10 feet, and have transverse pieces, called purlins, let into them to support the common rafters, placed at closer intervals, to which the boarding is fastened. See Fig. 2754, *C*.

The mansard-roof (8) has two sets of rafters, the upper set

Fig. 4420.





Roofs.

having a less inclination than the lower. The latter brace the upper ends of the queen or side posts, which, by means of the struts *i i*, assist in supporting the straining-beam; this depends from the upper pair of rafters by a center post and side posts; the upper rafters are braced by struts from the center post.

In the arched roof (9) two stretchers or hammer-beams *k k* are substituted for the tie-beam. These are held partly by their pressure against each other and partly by the king or center post, and are tied to the feet of the rafters.

10 illustrates the roof-framing of the circus at Edinburgh. It will be seen that the downward pressure is distributed upon the rafters *a a* and stretchers *b b′*, which are so tied together by straps as to bring the stress of the outward thrust ultimately upon *b*.

11 covers the principal apartment of the Episcopal Palace at Auxerre, France. Two sets of stays *g g′* are inserted above the tie-beam, between the king-post and principal rafters; a series of curved ribs receives the ceiling plank

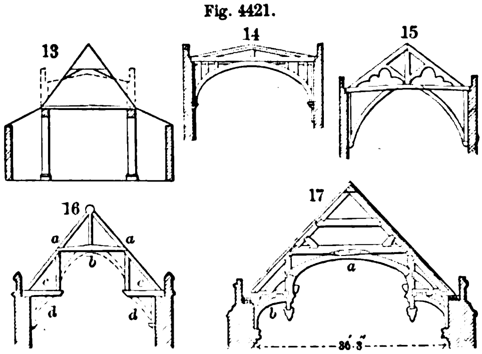
12 is a Norman roof; so called because it was introduced by that people into Southern Europe. The rafters *a a* butt against joggles on the king-posts *b b*, between which braces are disposed.

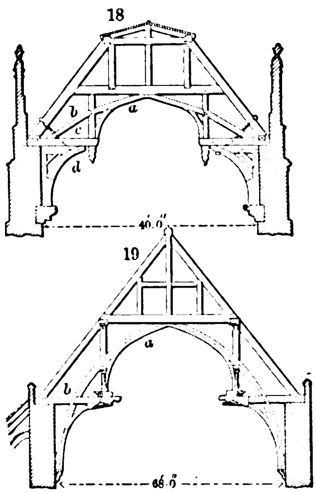
13 shows in dotted lines a way by which a pointed Gothic roof was converted into a flat roof by carrying the nave walls up so as to obtain a clere-story.

In 14, the tie-beam is supported at the center by struts from the main beam. A post resting on the tie-beam supports the rafters at the ridge.

15 resembles in appearance a king-post roof, but is in fact supported by the girders, which perform the office of a tie-beam, and are themselves sustained by wall-posts, so as to distribute

Fig. 4421.





Roofs.

the pressure over a considerable surface at the upper part of the wall.

16 is a form of roof common in Gothic constructions. The principals *a a* are connected by a *collar-beam* or *wind-beam b*, and are supported by *hammer-beams c c* resting on the walls and on curved struts *d d* attached to posts supported by corbeling. Auxiliary struts are introduced between the collar-beam and queen-posts, the whole being so disposed as to produce the effect of a vaulted ceiling. In the roof of the hall at Eltham Palace, Kent (17), the whole weight is thrown on the top of the wall; the bottom pieces *b* are merely ornamental, the tension-pieces *a* forming a complete tie.

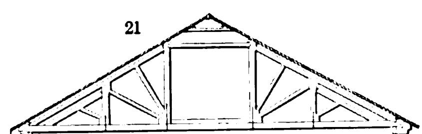
The roof of the great hall at Hampton Court (18) is so arranged that the beams *a b c* serve as ties; the curved struts *d* distribute the pressure over the wall and its sustaining buttress.

In (19) the roof of Westminster Hall, the weight rests entirely on the upper part of the wall; the arched rib *a* distributes the thrust and assists in preventing the hammer-beams *b* from sliding on the walls

Westminster Hall was erected under the orders of William Rufus at the latter end of the eleventh century. It is 274 × 74 feet, without a pillar. The room and the roof are equally admired. William said it was only antechamber to the one he would build; but that arrow of Sir Walter Tyrrel upset this calculation.

21 illustrates a queen-post roof of 80 feet span, covering the theater at Birmingham, England.

Fig. 4422.



Queen-Post Roof, Birmingham Theater, England.

Iron roofs were first used in England, and were the subject of a patent by Robert Ransome, 1783.

They are composed of essentially the same members as those of timber, malleable rods or flat bars

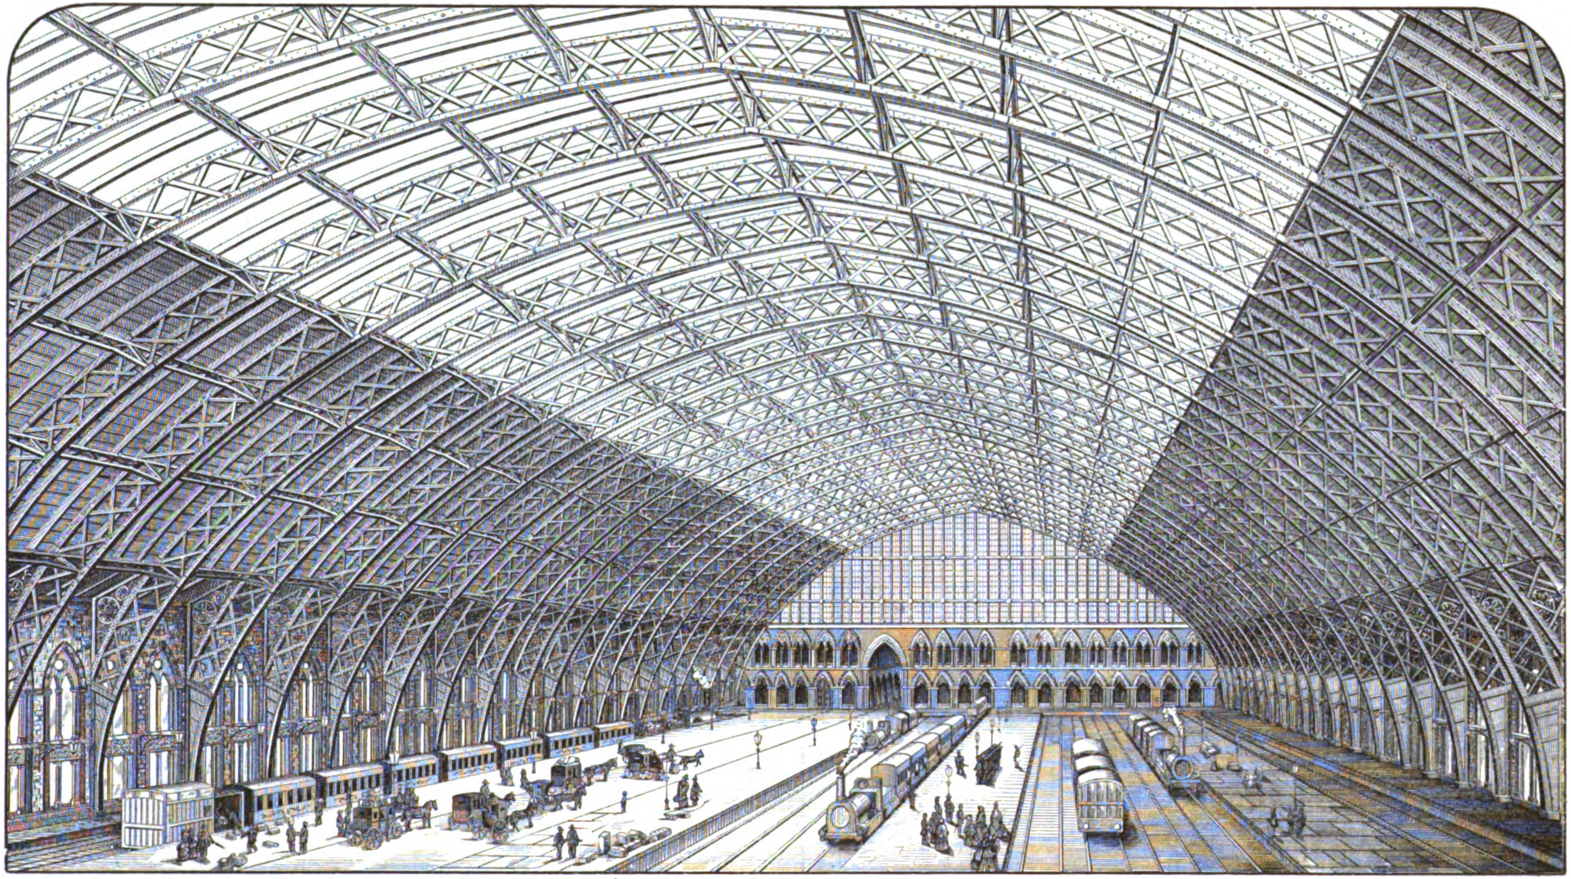


PLATE LII. ROOF OF THE PANCRAS STATION, MIDLAND COUNTIES RAILWAY, LONDON, ENGLAND. *See page 1973.*

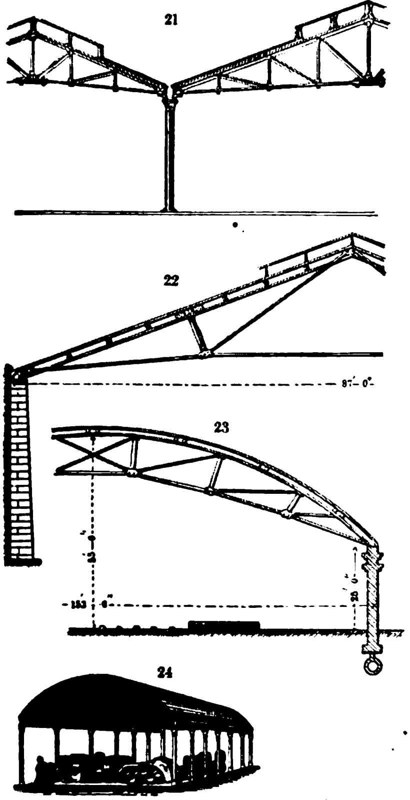
being substituted for the tie-beams and king-posts, and the rafters and posts made of sufficient stiffness with bars of malleable L or T iron, or with cast-iron of suitable form and section.

The meeting points of the several parts of each truss are provided with cast-iron shoes, sockets, and connecting plates, into which the ends of the rafters, struts, and rods are secured with screw-bolts and nuts or gibs and keys.

The roof of Smithfield Market, Manchester, is one of the simplest forms (21, Fig. 4423); its total width is 244 feet, covered by two outer spans of 50 and two central spans of 72 feet each, supported on cast-iron pillars.

Fig. 4423.



Iron Roofs.

22 is the roof of the Providence Magazine at Paris. It has 87 feet span. The roof of the railway station in Lime Street, Liverpool (23), has a span of 153 feet 6 inches. 24 is an ordinary freight-depot with iron roof and columns.

The roof of the Pancras Station, Midland Railway, London, has the widest span of any roof, unbroken by ties or braces. It covers ten acres. It is illustrated on the opposite page, Plate LII.

The length of the roof is 690 feet, with a clear span of 240 feet, covering five platforms, ten lines of rails, and a cab-stand 25 feet wide, thus making a total area of 165,600 square feet. Its hight at the ridge is 125 feet above the level of the road. There are twenty-five principal ribs in the roof, each weighing about 50 tons. Between each of these, which are about 29 feet 4 inches apart from center to center, are three intermediate ribs, carried by trussed purlins, constructed so as to stiffen the bottom flanges of the main ribs laterally. The station walls rise behind the spring of the principal, the space at the top being filled in with open iron-work

The roof is glazed about 70 feet on each side of the center, and the remainder is covered with slates on boarding one inch and three eighths thick, grooved and tongued and chambered, the under side being varnished.

The transverse girders which support the floor of the station take the thrust of the roof. They are connected so as to form continuous girders across the station. Besides being tied to them, the feet of the ribs are each secured by four 3-inch bolts to an anchor-plate built into the wall and strongly fastened.

The rail level of the station is about 17½ feet above that of the adjoining streets, thus affording very extensive cellarage. See also Plate III.

Among other kinds of roof-coverings may be cited: —

Metal in sheets, seamed and painted.

Fabric or paper saturated in tar and covered with sand and gravel.

Fabric or paper treated with a material which will resist sun, rain, and frost. Among the compositions for this purpose are the following: —

West, 1855. Gutta-percha; oil.

Billings, 1856. Shellac, 50 pounds; rosin, 120 pounds; linseed-oil, 10 quarts; steatite, 150 pounds.

Smith, 1857. Coal-tar, 21; linseed-oil, 1.

Milks, 1857. Naphtha, 20 gallons; turpentine saturated with asphaltum, 2 gallons; alcohol saturated with shellac, 2 gallons; turpentine saturated with caoutchouc, 2 gallons; linseed-oil, 1½ gallons; steatite, 10 pounds; gypsum, 1 peck.

Lighter and Morrell, 1857. Coal-tar, 1; pine-tar, 50; rosin, 12; caoutchouc, 6; gutta-percha, 6; asphaltum, 12; shellac, 6; linseed-oil, 12; litharge, 6; fire-proof material to be scattered on surface of the above, 12; yellow ocher, 12; beeswax, 3.

Oaks, 1859. Coal-tar, 25 gallons; linseed-oil, 2 gallons; caoutchouc, dissolved, 2 gallons; shellac, dissolved, 2 gallons; asphaltum, 5 pounds; steatite, pulverized, 5 pounds; litharge, 5 pounds; sulp. baryta, 5 pounds; gypsum, 5 pounds.

Grant, 1862. Coal-tar, 25 gallons; linseed-oil, 3 gallons; caoutchouc, dissolved, 3 gallons; shellac, dissolved, 1.5 gallons; asphaltum, dissolved, 2.5 gallons; Japan varnish, 2 gallons; white-lead, 25 pounds; mineral paint, 60 pounds; yellow ocher, 6 pounds; acetate lead, 5 pounds.

Wauzer, 1862. Pitch, 1; quicklime, 2; Ven. red ocher, 2; linseed-oil, 0.5.

Fuller, 1863. Saturated sheets of paper.

Wheeler, 1866. Coal-tar, 20 gallons; linseed-oil, 2 gallons; shellac, 10 pounds; rosin, 4 pounds.

Stead, 1866. Paint-skins, broken up; potash, 2 pounds; water, 1 gallon; linseed-oil, 2 gallons. Boil to evaporate water, and add mineral paint, 10 pounds.

Fields, 1867. Coal-tar, 1 barrel; fire-clay; silicate of iron; silicate of magnesia; linseed-oil, 1 gallon; litharge, 3 pounds.

Hutchings, 1868. Rosin, 1 pound; leached ashes, 1 pound; whiting, 0.5 pound; salt, 0.5 pound; red-lead, 0.12 pound; linseed-oil, 0.12 pound.

Irish, 1868. Gypsum, 10 pounds; water, 1 gallon; linseed-oil, 0.5 pint; white-lead, 0.08 pound; turpentine, 1 ounce.

Hinman, 1868. Coal-tar, 1 barrel; glycerine, 2 gallons; oil, 2 quarts; caoutchouc, dissolved, 3 pints.

Capron, 1868. Coal-tar, 40 gallons; acetate lead, 5 pounds; Japan varnish, 2 gallons; caoutchouc, 4 pounds; shellac, 4 pounds; linseed oil, 2 gallons; turpentine, 2 gallons; alcohol, 2 gallons.

Hutchings, 1869. Rosin, 1 pound; linseed-oil, 0.3 pound; covered by sifted sand, 4 pounds.

Joy, 1869. Coal-tar, 1 barrel; linseed-oil, 3 gallons; compounded with pulverized clay and sand, equal parts.

Dumpleman and Dotch, 1869. Coal-tar, 1 barrel; pine-pitch, 1 barrel; sulphur, 15 gallons; litharge, 2 pounds; pulverized slate, 2 pounds; linseed-oil, 2 gallons.

Fisk, 1869. Linseed-oil, 1; rosin, 5; petroleum, 1; pitch, 5; tar, 5. Mix with gravel, broken stones, or cinders.

Ruttkay, 1870. Linseed-oil; pulverized stone; litharge; chalk.

Ruttkay, 1870. Sifted gravel, 3; pulverized brick, 0.5; litharge, 0.12; linseed-oil, 0.25; Japan varnish, 0.08.

Barnes. Coal-tar, 40 gallons; pulverized slate, 30 gallons; pulverized clay, 10 gallons; boiled rice, 5 pounds; glue, 1 pound; terra de sienna, 1 pound; linseed-oil, 1 gallon. Mix the coal-tar, slate, and clay together. Boil the rice and strain it through a fine sieve, and liquefy the glue by heat. Add the rice, glue, and terra de sienna to the linseed-oil, and incorporate. Apply with a brush or trowel.

See L. W. Sinsabaugh's "Digest of Paving and Roofing Compositions," Washington, 1875.

2. The ceiling of a mine.

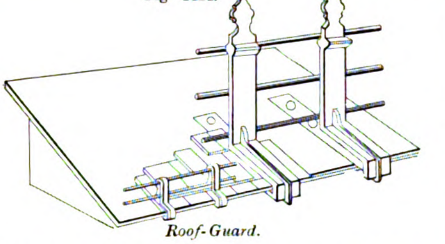
3. The top of a standing-top carriage, coach, or car. The central, raised portion of a car-roof is the *dome*.

4. The arched top of a reverberatory furnace.

Roof-guard. (*Building.*) A device for preventing snow from sliding from a roof. It consists usually of a continuous series of horizontal slats, slightly raised above the roof-cover and supported by uprights. In the example, the frame is attached to the sheathing beneath the shingles and carries horizontal longitudinal bars.

Roof'ing-ma-chine'. One for preparing mate-

Fig. 4424.



Roof-Guard.

rial for roofing purposes; saturating or paying fabric or paper with a water-resisting compound, or preparing metallic plates for roof covering.

Haven, 1857. The sheet is drawn down through a hopper containing tar, and passes out between pressure-rollers.

Davis, 1858. The canvas is drawn through a vat containing coal-tar.

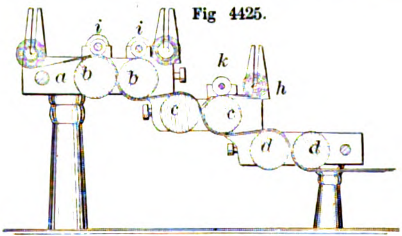
Pomeroy and Allen, 1859.

Anderson, 1861. Steam-pipe to heat composition.

Robinson, 1865. Coat sheets of felt, etc., with asphalt on one side, the other being supported by a roller. Sheets cemented together between pressure-rollers.

Fig. 4425 is a machine for preparing roofing fabric by passing sheets of felt or other material between rollers, the asphalt in a

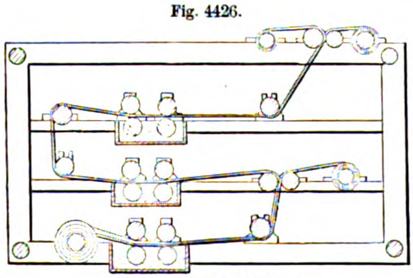
Fig 4425.



Robinson's Roofing-Machine.

plastic state being applied between the sheets as they pass between the rollers. The upper rolls of paper are shown in the holders from which the sheets pass beneath rollers *i i*, and are compacted together with an included thickness of asphalt by the pressure of rollers *b b*. A third sheet of paper comes from roll *h*, passes beneath roller *k*, and is compacted with the former sheets by rollers *c c*. The three-ply roofing-paper receives its final pressure between rollers *d d*. The material used upon the paper is coal-tar, or Trinidad pitch, with 60 per cent of earthy matter, chiefly clay, though lime and sand may be used. Fig.

Fig. 4426.



Roofing-Fabric Machine.

4426 is a modified form in which the strips of paper are tarred, cemented, and pressed together by passage between rollers. The tarring-rollers rotate in fountain-troughs, and raise the contents into contact with the paper.

Pulte, 1866. Hopper and movable gate. Felt drawn over a roller in the bottom of the hopper.

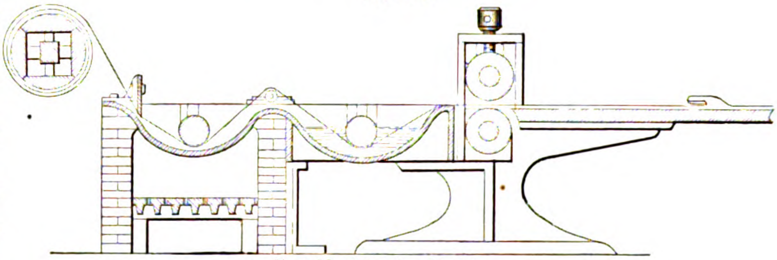
Brown, 1869. Mixing vessel with steam-jacket and beaters. Sand-box and movable apron for carrying along the materials.

Cobb, 1869. Tank, sand and gravel box, and pressure-roller, so as to make the operation on the paper continuous.

Benton, 1869. Felt or paper placed on a bed, and the tar-hopper moved over it, spreading the tar. Sand operation similar.

Fig 4427 is a machine for forming sheet-metal plates into continuous strips for roofing, the strips being afterward joined together on the roof. The ends of sheets or strips of metal are interlocked, and the metal then passed between rollers to close the seams, and then through a bath of molten tin or other soft metal, which coats the surface and closes and covers the

Fig. 4427.



Sheet-Metal Roofing-Machine.

seams, so as to form continuous pieces, of indefinite length, without appreciable or pervious joints.

Roof-Seaming Machine.

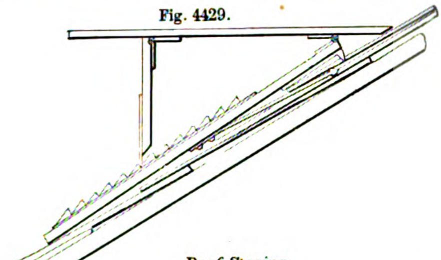
Roof-seam'ing Ma-chine'. A device for unit-

ing the joining edges of sheet-metals in covering roofs.

The double-seaming tool for roof consists of blocks *A E*, which pinch together the upturned edges of the adjacent sheets when the handles *C D* are grasped, as shown in sections 2 and 3 of the figure. By then turning the lever *F*, the block *B*, which is journaled in the ends *a a*, is laid over against the block *E*, carrying with it the taller of the two strips, as shown at 4 and 7. The bending apparatus is then shifted along half its length, and the other part of the block *B* acts upon the bent-over edge of the strip, as shown at 5 and at 8. The sole-pieces *e m* are now taken out, which lowers the blocks *A E*, and the process is repeated, as shown at 6 and 9. See also DOUBLE-SEAMING MACHINES.

Roof-stag'ing. A scaffold for resting upon a slanting roof while shingling, slating, repairing, or painting. The barbed rod is thrust up beneath a course of shingles, and the barbs hold in the course

Fig. 4429.



Roof-Staging.

both above and below. The claw-plate holds to the top of the roof, and serves, with the barbed rod, to hold the plank to which the bracket is hinged and braced.

Roof-truss. The framework of a roof, consisting of thrust and tie pieces. See ROOF.

Rook'er. (*Bakery.*) A tool like the letter L, used for withdrawing ashes from the oven.

Room. (*Mining.*) The worked space in a mine, especially of a coal-mine, where the roof is supported by regular pillars. The whole winning is thus said to be worked with *pillar* and *room*, or *post* and *stall*, — the same thing. *Thirlings* are worked spaces connecting *rooms*, and the cutting of the *thirlings* changes a *wall* to a row of *pillars*.

Room and Space Staff. (*Shipbuilding.*) A long measuring-rod used in spacing and regulating the distances apart of a ship's frames.

Room and space is the distance between the stations of the timber frames which constitute the ribs. It varies from 2 feet 6 inches to 3 feet 9 inches. *Room* is the rib; *space* the distance apart.

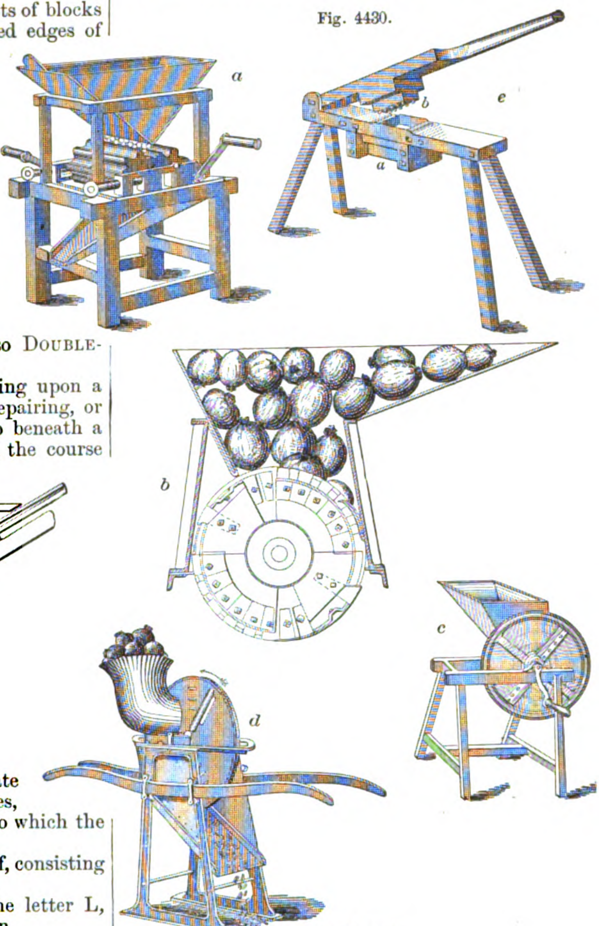
Room-pa'per. Wall-paper. Paper-hangings.

Root. (*Hydraulic Engineering.*) The end of a weir or dam where it unites with the natural bank.

Root-bruis'er. (*Agriculture.*) A machine for mashing or bruising potatoes, turnips, carrots, or other raw roots for feeding stock. The machine *a*, used in Britain, has two widely fluted rollers placed under a hopper and turned by two hand-cranks. The pomace falls into a chute, which delivers it into a tub. The object is to obtain the root in such a shape as to be more digestible and less likely to choke the animals.

The feeding of turnips, mangel-wurtzel, and other roots has become a regular part of the system of British husbandry. To bring the roots to a convenient size for the stock and to remove

Fig. 4430.



Root-Machines.

the danger of choking, root-cutters were introduced. These at first consisted of wheels or reciprocating blades, which cut the root into broad and thin slices; but, by an additional set of knives, these broad slices are cut into pieces about the size of one's finger.

There are three different forms of turnip-cutters in use in Britain. One has knives placed on a disk; another, knives placed on a cylinder; and lastly, knives working through a grating by a crank motion.

In the first form, a series of knives are placed in the face of an iron disk by screws. The turnips are placed in a hopper set at an angle, so that they may press by their own weight against the disk.

The knives are of two kinds; one flat and extending from nearly the axle to the outer edge of the disk, and at a distance from it equal to the thickness the slice of the turnip is required to be.

If only slices are required of the full breadth of the turnip at the part it is cut, then this knife is used by itself; but if it is necessary that the turnip should be cut into sections the cross-way of the cut, as for sheep, then a series of small knives, projecting from the face of the disk at right angles, are placed at distances apart equal to the width required The pieces, after being cut, fall into the receptacle beneath.

Gardner's root-cutter (English), *b*, has curved peripheral knives which remove the slices from the roots in the hopper, and radial knives which give preliminary gashes in the roots before the curved knives reach them, so that the slices removed by the latter fall into pieces and drop into the basket below. The illustration shows two of the peripheral knives, each preceded by a set of slitters, which are arranged in a V-form, on the face of the cylinder, so as to come in action in turn.

The knives of the root-slicer *c* are attached to the arms of a

fly-wheel and act upon roots presented at a side opening at the lower part of the hopper. By having two sets of knives, one to *cut into* the root to a certain depth, and the next to *cut off* a slice, the roots are reduced to strips, as in Baird's machine (*d*). The cutter-wheel of this machine is thickened toward the edge, to give it the effect of a fly-wheel. The knives are set to a distance from the face of the disk according to the thickness of the slices required. Each knife is preceded by three or more lancet-pointed studs, which slit the roots in passing and prepare the slices for falling into pieces as soon as they are detached from the root by the radial knives, which are parallel with the disk-wheel.

Where roots are fed upon the ground, a chopper is used to divide the root, to bring it to a more convenient size and a shape less likely to choke cattle.

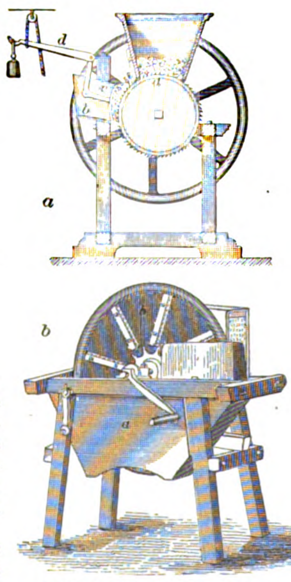
A simple device (*e*) for cutting roots consists of a box *a* with a row of sharp knives in the bottom, their edges presented upwardly. This is secured to a bench, and above it is a pivoted lever having on its lower side a block *b* fitting the box and provided with studs agreeing in position with the openings through which the slices are to be thrust. The roots are fed into the box, and by the descent of the lever are driven out below, being divided by the sharp-grated bottom. See VEGETABLE-CHOPPER; VEGETABLE-SLICER.

Root-dig′ger. (*Agriculture.*) An implement for pulling up fusiform roots, as beets, carrots, etc. The example (Fig. 4431) has jaws, each of which forms part of the semi-frustum of a hollow cone, affording a firm hold on the upper part of the root. See also POTATO-DIGGER.

Fig. 4431

Root-Digger.

Fig. 4432.



Root-Grinder and Root-Pulper.

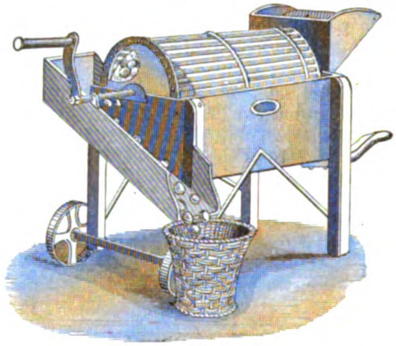
Root-grind′-er. A machine (*a*) for comminuting roots for the purpose of obtaining starch, sugar, or color from them.

Instances of its employment are found in grinding potatoes for starch, beets for sugar, madder for dye. One form of the mill is shown in the cut. The cylinder of sheet-metal (*a*) is punched from the inner surface so as to leave sharp projecting burrs which form teeth. The roots are placed in the hopper above, and are partially grated by the toothed cylinder as they pass from thence through the throat into a box *b*, where they are again subjected to the action of the grating cylinder, against which they are pressed by a follower *c*, which is pushed against them by a bell-crank lever and weighted arm *d*. From this box they are discharged into a trough beneath, for elutriation or pressure, as the case may be.

Root-pulp′er. (*Agriculture.*) A machine (*b*, Fig. 4432) for finely comminuting roots to serve as food for stock. In the example, the roots placed in a hopper *a* are acted on by a series of toothed knives radially arranged on the surface of an iron disk *b*, having a heavy rim which acts as a fly-wheel and is turned by a winch. The angle of the knives may be varied to cut more or less finely.

Root-wash′er. A machine which usually consists of a slatted cylinder revolving in a tank of water. The roots are subjected to mutual attrition and contact with the bars of the cage, so as to loosen the dirt, which settles to the bottom of the tank.

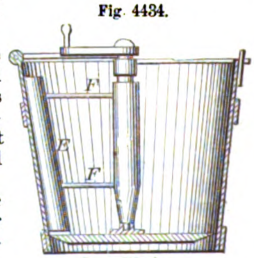
Fig. 4433.



Root-Washer.

A modification of the foregoing is made by an interior spiral chute, which acts on the principle of the conveyor, so that the roots which pass into the cylinder from the hopper at one end are carried along and discharged at the other, the operation being continuous.

Fig. 4434.



Root-Washer.

In another form, the potatoes, etc., are placed in a tube having arms *F F* and a sweep *E* attached to a vertical shaft whose rotation stirs and cleanses the roots.

Rope. A general name applied to cordage over one inch in circumference.

Ropes are of hemp, flax, cotton, coir, or wire, and are known by their construction; as,—

Cable-laid; three strands of *hawser-laid* rope, twisted right hand.

Hawser-laid; three strands of yarn twisted left hand, the yarns being laid up right hand.

Shroud-laid or *four-strand;* having a central strand slightly twisted and three strands twisted around it.

Hemp is laid up *right*-handed into *yarns*.

Yarns are laid up *left*-handed into *strands*.

Three *strands* are laid up *right*-handed into a *hawser*.

Three *hawsers* are laid up *left*-handed into a *cable*.

Coir ropes are made of the fiber of the cocoa-nut, and will float in water.

Wire ropes usually consist of six strands laid or spun around a hempen core; each strand consisting of six wires laid the contrary way around a smaller hempen core.

Sash-line; a rope of plaited yarns.

Ropes are known also by their purpose; as,—

Awning	**Brail.**	**Clew.**	**Entering.**
Bell.	**Breast.**	**Crown.**	**Fall.**
Boat.	**Bucket.**	**Crowfoot.**	**Foot.**
Bolt.	**Buoy.**	**Davit.**	**Gaub.**
Brace.	**Cat.**	**Downhaul.**	**Grab.**

Jaw.	Passing.	Spilling.	Yoke.
Jeer.	Pendant.	Stay.	

See also RIGGING.

A rope is —

Whipped, by winding twine around the end to prevent untwisting.

Payed, by painting or tarring to resist wet.

Served, by coiling yarn around it closely and tightly.

Parceled, by wrapping with canvas.

Puddened, by making a bulky cushion around a part to prevent chafing.

Stopped, when lashed; as the *end* to the *standing part* in a *hitch*.

Stoppered, when a rope is made fast to it to prevent veering.

Bent, when it is secured to an object by a hitch or otherwise. *Hitch*, *clinch*, and *knot* are forms of fastening. See KNOT.

Wormed, by laying a smaller rope or yarn in the lays of a cable. It is preliminary to *serving*. *Link-worming* is worming with chains.

Laid, by placing and twisting the twisted strands together in the operation of rope-making.

Grafting and *splicing* are modes of uniting one rope to another by interweaving the strands. See SPLICE.

Seizing and *lashing* are sailors' terms to express respectively the binding of one rope to another by a smaller rope or yarn, and the fastening of one object to another by similar means.

Pointing is a mode of finishing the end of a rope by tapering and braiding the strands.

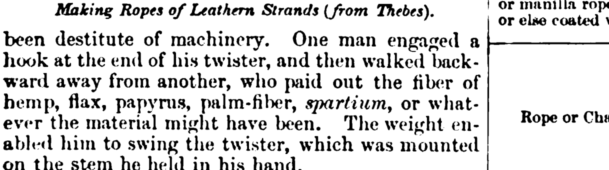
To *marle* a rope is to bind it with spun-yarn or twine, with a knot at each turn, so as to secure the wrapping if cut in one or more places.

Galvanizing is applied to iron-wire rope. It consists in coating the wire or rope with zinc.

Ropes were made of various materials in ancient Egypt, but especially of the papyrus and of leathern strands. The use of the papyrus in this connection has been described by Pliny, and is cited elsewhere in this work, as is also that of the *spartium*, which was employed extensively, though the particular variety was confined to moderate geographical limits. The *spartium* made a coarse article of cordage, as did the *leef* or fibers of the date-tree, which were used for ropes in ancient and in modern Egypt. For a finer article, flax was used. Pieces of ropes of these materials still remain as mementos of the ancient dwellers by the Nile.

The rope-makers of ancient Egypt seem to have

Fig. 4435.



Making Ropes of Leathern Strands (from Thebes).

been destitute of machinery. One man engaged a hook at the end of his twister, and then walked backward away from another, who paid out the fiber of hemp, flax, papyrus, palm-fiber, *spartium*, or whatever the material might have been. The weight enabled him to swing the twister, which was mounted on the stem he held in his hand.

In a tomb at Thebes, of the time of Thothmes III., the Pharaoh of the Exodus, is a group representing the process of twisting thongs of leather, which were fastened to the end of a tube, which revolved on a cord slung around the loins of a man who receded backwardly from the person who arranged and payed out the strands. The tube had, in all probability, a collar or sleeve which was grasped by the man, and had a bar and weight which caused it to rotate as it was swung around by the operator. The strands of the rope passed between the legs of the stool and between the feet of the man who arranged the strands and kept them from becoming entangled. The character of the material is indicated in the manner which is so peculiarly Egyptian, by the skin hanging up in the shop, and a man is shown cutting a continuous thong with a knife like our modern leather-knife, and by the same means which we adopt, by turning the piece of leather round as he cuts. Two of the coils are represented hanging up in the shop.

The process of preparing the hemp is shown in the tombs of Beni-Hassan and Thebes. Ropes of the palm are found in the tombs, and it was probably almost as common as *coir* or cocoa-nut fiber in India.

The ropes which supported the planks of the Hellespont bridge constructed for Xerxes were of papyrus and flax. These were the ordinary materials for the purpose in Egypt, from which country the king had a large contingent. See MILITARY-BRIDGE.

Ropes of goat's hair are mentioned by Aristotle and Virgil.

The famous vessel, the "Syracusia," built for Hiero, was furnished with hempen ropes from Rhodes, according to Moschion.

"The ropes of the Tartars are made of camel's hair or horse-hair." — Huc.

Coir rope is manufactured from the husk or pericarp of the cocoa-nut.

The nuts are picked a little before the fruit is ripe, and the rind separated by thrusting it upon an iron stake fixed in the ground. The rind is then water-soaked for several months, to separate the fibers from the interstitial matter, is beaten with a heavy mallet upon a stone, and then rubbed by the hands to rid it of the cellular substance. 40 cocoa-nuts yield 6 pounds of coir, which is twisted into yarns and made into mats or cordage.

Coir rope is more buoyant than hempen, and is an excellent material for hawsers.

Its strength, relatively to hemp, is, for large ropes, 87 to 108; for small ones, 60 to 65. It is not injured by sea-water, and is much used for running rigging, though from its contractibility it is not so suitable for standing rigging.

Wire rope appears to have been first used in the silver-mines of the Hartz Mountains, about 1831. They have since come into very general use for ships' rigging, as well as for transmitting power in other situations. Some ropes of this kind employed in the underground levels of the English coal-mines probably have a length of more than 3,000 feet. One constructed at the works of John A. Roebling, a few years ago, was said to be the longest, largest, and weightiest wire-rope ever made in one piece. It is 3,700 feet in length; its diameter is over 2¼ inches, and its weight some 20 tons. The machinery employed is said to be capable of making a rope twice as long and large as this one. The rope is used upon an inclined plane, for the purpose of raising coal out of the Wyoming Valley. See WIRE ROPE.

Various processes have been patented for making wire rope. For some purposes, untwisted wires bound together by hempen cord or inserted within canvas have been employed. More generally, however, a slight twist is imparted, and they are formed into strands, which are afterward laid up in a manner analogous to that used in making hempen or manilla ropes. The wires are galvanized, or rather zincked, or else coated with a preservative composition.

Rope or Chain.	Dimensions.	Multiplier for proof of strength.	Multiplier for weight of 100 fathoms.	Proof-strength in fathoms of rope or chain.
Hempen Rope.	Inches	Tons.	Tons.	
Hawser-laid	Girth squared	0.1875	0.0103	1,820
Shroud-laid	Girth squared	0.15	0.01	1,500
Cable-laid.........	Girth squared	0.12	0.0096	1,250
Wire Rope (36 *wires*).				
Iron..............	Girth squared	0.75	0.039	1,923
Steel.............	Girth squared	1.125	0.04	2,812
Rigging Chain....	Diameter of rod	12.00	2.9	414

The preceding are the ordinary rules for calculating the *proof* strength and weights of ropes and chains, in English tons (2,240 pounds); the dimensions being in inches.

The *breaking* load is from two to three times the above.

The old rope-makers' rule for hempen rope was to square the girth of the rope in inches, which, multiplied by 4, gave the ultimate or breaking strength of the rope in hundred weights; and it was a good rule for small cordage up to 7 inches in circumference.

The square of half the circumference was considered to represent the weight of a fathom in pounds.

What is believed to be the longest rope in the world is a grapnel rope, 10,000 fathoms long without a splice, and has been made for the Siemens Telegraph Company. It is made of three strands, the diameter of the completed rope being 2 inches.

The table below shows the comparative strength of various kinds of rope and chain, the sizes on each horizontal line being of equal strength.

Capacity of the Ropes and Chains.		Round Iron Wire Rope.		Round Steel Wire Rope.		Round Hemp Rope.		Flat Iron Wire Rope.		Flat Steel Wire-Rope.		Iron Chain.

The winding drums or pulleys for wire ropes should be one hundred times the size of the rope, and round ropes should lead fair on to and fit the groove of the pulleys.

All the ropes of a vessel composing the standing rigging, running rigging, ground tackle, etc., are distinguished by names corresponding to their uses, without reference to the make or size of the rope; thus, the cable of a vessel may be *hawser-laid*, or the hawser *cable-laid*. The following is a list of those technically termed *ropes*: —

Bell-rope; attached to the bell, on which the half-hours are struck.

Bolt-rope; that to which the head-leaches and foot of a sail are sewed.

Breast-rope; a band of canvas, secured at each end to the rigging for supporting the body of the leadsman while heaving the hand-lead.

Bucket-rope; a laniard attached to a bucket for dipping water from alongside.

Buoy-rope: a rope attached to the crown of the anchor, and to a buoy floating on the surface to show the position of the anchor when in the ground.

Clew-rope; a rope attached to the clew of a sail, and leading up forward; used in clewing up the sails for furling, and rousing the clew forward of the bunt.

Crown-rope: used at the corners of the cable tiers to keep the fakes in their places.

Entering or *man rope*: a rope secured at the upper end and hanging down the ship's side by the ladder for persons going up or down to hold on by. Also by the ladders at the hatches. The former may be termed *entering*, the latter *man* ropes.

Foot-rope. *a*. The bolt-rope at the foot of a sail.

b. The rope beneath a yard, or the bowsprit on which the men stand when furling or reefing sail; the former are also called *horses*.

Gaub-rope; a rope extending inboard from each leg of the martingale to secure it.

Grab-rope: used to confine the bunt of a sail in furling.

Guest or *guess rope*: a rope used for towing a boat or vessel.

Guy-rope; used for steadying a purchase, spar, or other similar object. See GUY.

Head-rope; the upper bolt-rope of a square sail

Heel-rope: a rope secured to the heel of a mast or boom to rouse it down, out, or in by, or to lash it.

Jaw-rope; a rope or parral secured to the jaws of a gaff and passed around a mast; it is often provided with rollers to enable it to slide up and down easily.

Man-rope. See *Entering-Rope*.

Mast-rope; a rope used for hoisting and lowering masts.

Parral-rope; a single rope secured at the slings or centers of yards, and passed around the mast. Used only on light yards.

Ring-rope; a rope rove through the ring of the anchor and secured to the end of the cable

Slip-rope: used to suspend the bight of a hawser or cable.

Tiller-rope; a rope connected to the end of the tiller and wound around the barrel of the steering-wheel.

Top-rope: a rope used in swaying up a topmast. It is rove through the top block, hooked in the cap, and through the heel of the topmast.

Yoke-rope: a small rope attached to each end of the yoke by which a boat is steered.

Round-in; to haul upon a rope; generally used with reference to the weather-braces.

Round-up; to haul up; generally applied to the act of hauling up the slack of a rope through its leading block or a tackle, which hangs loose by its fall.

Rouse; to haul or pull together on a rope.

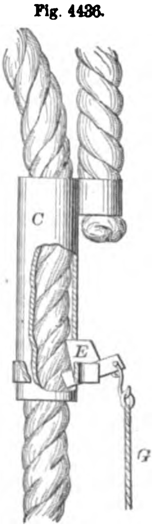
Rope Bridge. Bridges of rope were probably first constructed in China. They are of frequent occurrence among the Andes of South America, where the ropes are made of ox-hide thongs twisted together; two are usually employed, their ends being attached on each side of the chasm; transverse pieces are lashed to them, over which the flooring is laid; in other cases but a single rope is employed; from this a hammock or basket is suspended, and drawn from bank to bank by a rope at each side.

A rope bridge may be made by placing a trestle at the midlength of a set of suspension ropes and laying two or more beams from each bank to this trestle to support the roadway. When a stream is too wide to be spanned by a single length, a mast may be erected in the middle, and steadied by guys from each shore; the ends of the rope are attached to this, and the beams supported by other ropes depending from it. In some cases masts are erected on both banks, and the ends of the suspension-ropes attached to their tops; ropes hanging perpendicularly from these, and other ropes extending diagonally from the masts, support the timbers carrying the roadway; in this case the construction resembles that of a wire bridge. See SUSPENSION-BRIDGE.

In all cases, especially where the structure is of considerable length, guys extending up and down stream should be attached to the bridge at suitable points, particularly at and near the center, to check its vibrations.

Rope-clamp. A device by which a rope is compressed in order to restrain its motion. In the example, the rope passes through the sleeve *C*, and may be checked

Fig. 4436.



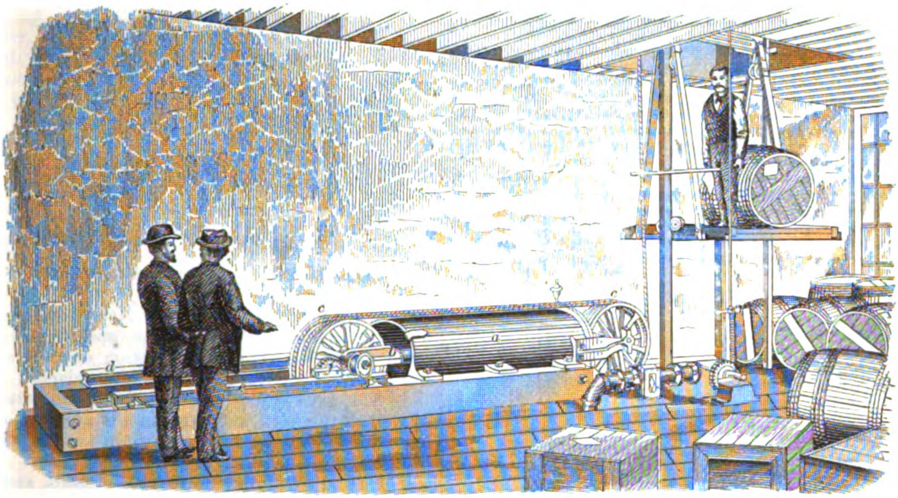
Rope-Clamp.

or held by the pivoted tooth *E*, which is vibrated by the cord *G*. See CABLE-STOPPER.

Rope-clutch. A device for holding fast a rope, consisting usually of two movable jaws, or a movable and fixed jaw, which are caused to nip the rope by pulling a cord, or sometimes by automatic devices. See CABLE-STOPPER.

Rope El'e-va'tor. An elevator in which the platform or cage is raised and lowered by means of a rope and winding mechanism.

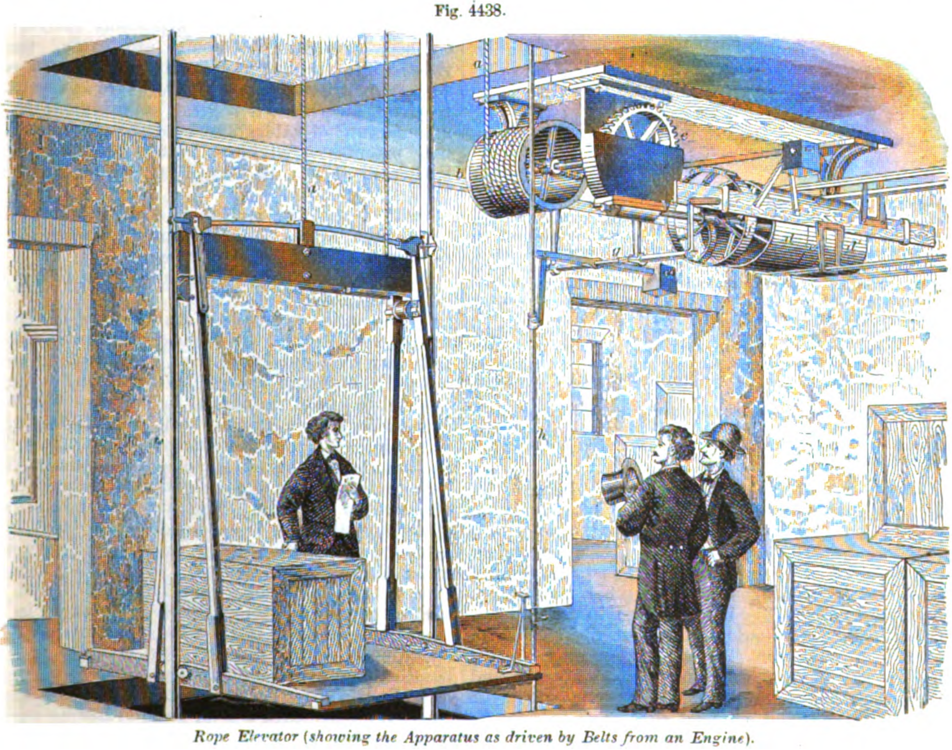
Fig. 4437.



Rope Elevator (showing the Hydraulic Machine in the Cellar).

In Fig. 4437, steam admitted to the closed end of the cylinder *a* operates a piston carrying a cross-head *b* having a jaw at each side, in which the drum *c* is journaled; as this advances along the guides *d e*, it is at the same time rotated by a pinion *f*, which engages with a rack on the bed and a pinion on the drum-shaft. The drum *c'* remains stationary, and the amount of rope taken up, and consequently the

Fig. 4438.



Rope Elevator (showing the Apparatus as driven by Belts from an Engine).

length of hoist, is equal to the length of traverse of the drum *c* multiplied by the number of turns of the rope around it.

Safety-catches are provided to arrest the platform in case the rope should break.

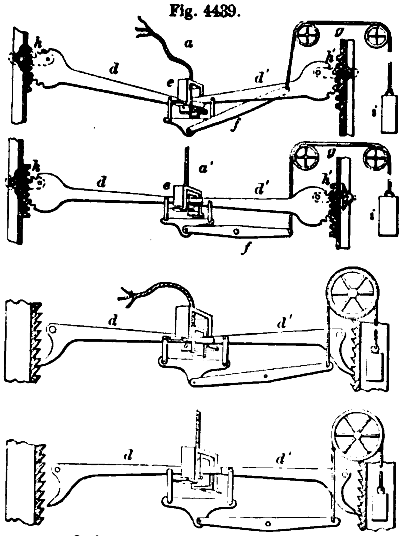
When steam is permitted to escape from the cylinder *a*, the weight of the platform causes it to descend, partly uncoiling the rope from the drums *c c'* and restoring the drum *c* and piston to their first position.

The hoisting-rope *a* of the elevator (Fig. 4438) passes over a grooved wheel in the upper story, and is wound upon the drum *b*, which is turned by the wheel *c* gearing with a worm on the shaft of the fast pulleys *d d'*; one of these is driven by a straight and the other by a crossed belt, by shifting one or the other of which from the loose central pulley *e* to its own proper pulley, the shaft is rotated in contrary directions, and the elevator raised or lowered.

The brake-wheel *f* is acted on by the device *g*, connected with the rod *h*, which extends from the top to the bottom of the building, and may be operated from either floor.

The safety-cage *a a'*, and that shown in the two succeeding figures, are each operated by a weight and a cord passing over one or two pulleys. The safety-catch is shown at *a'* in its normal

Fig. 4439.



Safety-Catcher for Rope Elevators.

position, with the hoisting-rope intact; the two levers *d d'*, whose inner ends, passing each other, are supported on a pin within the box *e*, are connected by links to a cross-head, to which one end of the lever *f* is pivoted, the other end being connected with the check-rope *g*. The toothed-cam ends of the levers *d d'* are connected with the racks *h h'*, with which they mesh, rising and falling with them. They are also connected by straps with shoes behind the upright guides. Should the hoisting-rope break, as shown at *a*, the weight *i* is brought into action, depressing, through the lever *f*, the inner ends of the cam levers *d d'*, bringing the shoes into contact with the back of the guides, and preventing descent of the apparatus.

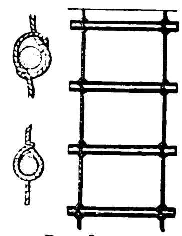
In the two lower figures, the levers *d d'* are, in case of breakage of the rope, actuated in a precisely similar manner, causing detents at their outer ends to enter notches in racks on the guide-frames.

Rope-guard. A device to prevent chafing. In Fig. 4440, a hollow metallic knob is held at the exposed point by a pin passing through the rope.

Rope Lad'der. (*Nautical.*) Rope ladders are employed for enabling persons to ascend and descend from the deck of a ship or from her booms into boats alongside. They are also used in fire-escapes. Other uses will doubtless suggest themselves to readers of romance. The side pieces only of side ladders are of rope, the rungs being of wood, and secured as shown in the cut. Those by which the rigging is ascended are termed *shrouds*. A *Jacob's ladder*.

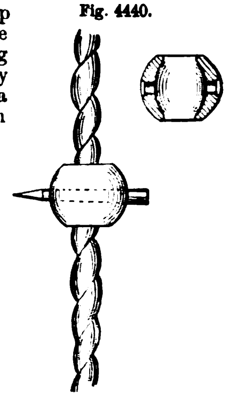
Rope-ma-chine'. Hemp is mentioned by Pliny as the favorite material for making ropes. *Spartium*, a variety of the broom growing on a tract of ground lying upon

Fig. 4441.



Rope Ladder.

Fig. 4440.



Rope-Guard.

the sea line of the province of New Carthage, was used for common rope or cordage, and also for some other purposes. The outer portion of the papyrus was also used by the Egyptians for cordage.

In fact, most vegetable fibers of sufficient strength, as well as the hides and intestines of animals, are, or have been, used at different times and in various countries for this purpose.

The twisting of the fibers into strands, and *laying up* these into rope, was, from the earliest times until a comparatively recent period, almost entirely effected by manual labor; the simple means by which the process was effected hardly deserving to be called machines. A machine for this purpose was patented in England by Richard March in 1784, and another by Edward Cartwright in 1792. In 1805, Captain Huddard invented a series of machines, in which some of the features of the latter were introduced, by which hemp was successively combed, straightened, spun into yarns, tarred, twisted into strands, and finally laid up into rope. These were introduced into the dockyard at Chatham, England, and effected a great improvement in the manufacture of cables and cordage. See also English patents, — Sylvester, 1783; Seymour, 1784; Fothergill, 1793; Balfour, 1793, 1798; Chapman, 1797, 1799, 1807.

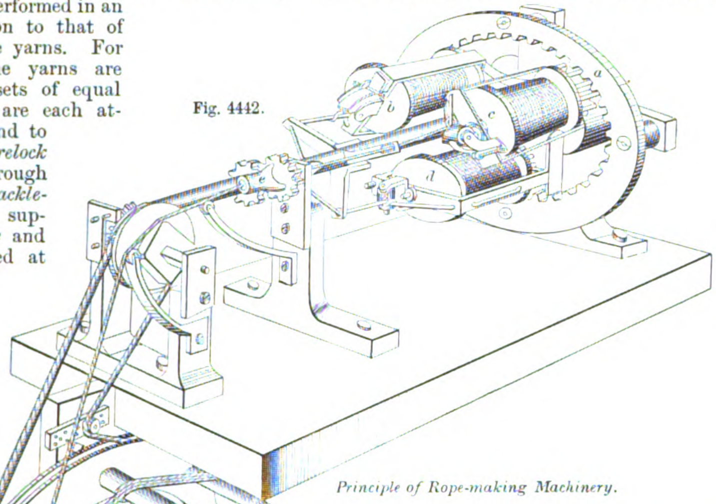
In the year 1820, machinery was introduced into the United States from England, for working the spun yarn into strands and ropes.

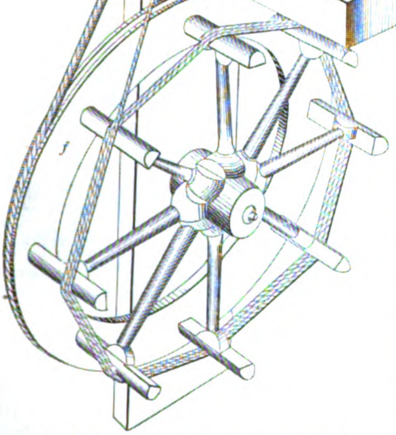
Mr. Treadwell introduced his rope-making machinery in 1834.

In the ordinary process of manufacture, the hemp, having been heckled and formed into skeins, is spun into yarn by a number of men, each of whom wraps a bundle of hemp around his body, and attaches one end to one of a series of hooks rotated by band connection with a crank-wheel, and walking backward along the ropewalk draws out the fibers from the bundle with his left hand and compresses them between two fingers of the right, until he reaches the other end of the walk. The thickness and hardness of twist of the yarn is governed by the quantity of hemp fed out by the spinner, and the rapidity with which the hooks are revolved. The yarn is then detached from the hook, wound on a reel, and the spinner proceeds as before, working this time in the opposite direction. If the rope is to be tarred, this operation is next performed. 300 or 400 yarns are bundled together, forming a *haul*, which is dipped into a kettle of tar heated to about 212°, and drawn through a hole called a *grip*, *gage*, or *sliding-nipper*, which presses the tar into the fiber and squeezes out

the superfluous portion. The yarns, either tarred or untarred, are next twisted or *laid* into strands, the twisting being performed in an opposite direction to that of the fibers in the yarns. For this purpose the yarns are made up into sets of equal number, which are each attached at one end to a winch or *forelock hook*, passing through holes in the *tackle-board*, and are supported on *stakes* and *stake-heads* placed at intervals along the walk; when they have become shortened by twisting, they are detached from the posts to which their other ends were fastened, and these are attached to a *sledge*, which is loaded with weights, so as to keep the strands taut, yet yield as they become farther shortened by twisting. When each strand has become *full hard*, they are detached from the tackle-board, and the three are placed in the three grooves of a conical wooden block termed a *top*, through which is passed a transverse stick forming the handles or *woolders;* one end of each is fastened to the center hook of the tackle-board, and the other to one of three hooks in the breast-board of the sledge; these are turned in one direction, while the tackle-board hook is turned in the other. The top, having been inserted between the strands as closely as possible to the tackle-board, is gradually forced along as the twisting proceeds, until it is brought up close to the sledge, the strands closing in behind it as it advances.

Fig. 4442.



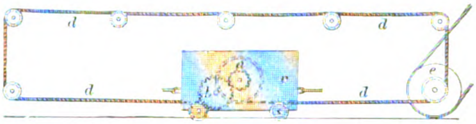


Principle of Rope-making Machinery.

By another arrangement, a carriage *c*, which is caused to traverse from one end to the other of the walk, is substituted for the sledge. This carries a frame and wheel, having spindles on which the strands are wound, forming the equivalent of the breast-board. The wheel is caused to rotate in one direction and the spindles in another, by gearing driven from the ground-wheels of the carriage as it is moved along the walk by means of the ground-rope *d*.

In the illustration, this is shown as passing around a drum on the driving-pulley *e*, and supported by overhead pulleys; it passes around the pulley *a*, on the carriage, whose axis has a pinion that turns the wheel *b*, which by means of suitable interior gearing causes the twisting-wheel and its spindles to revolve as described, and also gears with the ground-wheel of the carriage to give it a forward or backward motion.

Fig. 4443.



Ground-Rope.

The ground-rope may simply be employed to turn the twisting mechanism, the carriage being moved back and forth by ropes at each end; or, as shown at *g d'*, two ground-ropes may be used, by one of which *g* moves, as shown above, and imparts the traversing motion to the carriage, while the other, *d'*, passing around the smaller pulley, is fixed at each end, and causes rapid rotation of the operative machinery.

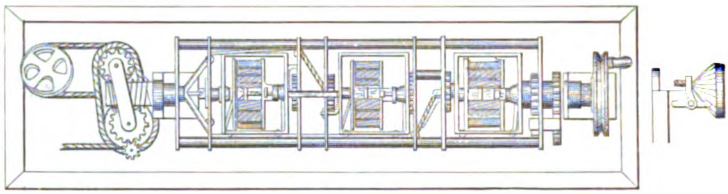
The principle on which the coarse fibers of hemp, coir, manilla, etc., are spun into rope-yarns is essentially the same as that by which yarns or threads for making fabrics are produced. For forming the first into the cords or strands which are twined together to constitute ropes, it is necessary that each of the spools on which the strands are reeled should rotate on its own axis, in order that the strands may freely unwind, and also that they should have a combined revolution around a common axis to twist the strands together.

In the machine (Fig. 4442), this is effected by the fixed sun-wheel *a*; the three spools *b c d* have planet-wheels at their ends, meshing with the teeth of the sun-wheel, and as they revolve on a common axis

concentric with its center, rotate independently on their own journals. The rope is conducted through the hollow rotating shaft *e* and wound upon the reel *f*, whose velocity is such as to take up the rope as fast as twisted and always maintain an equal tension.

The principle is farther illustrated in Fig. 4444, in which the main frame revolves in one direction and the inner frames with their reels revolve in the opposite direction: the threads and cords are respectively and successively associated and entwined to form a complete rope.

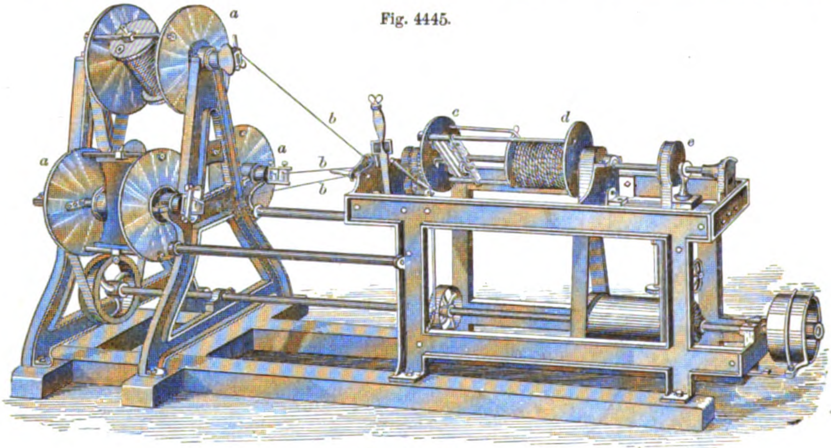
Fig. 4444.



Blackie's Rope-Machine.

The machine (Fig. 4445) is particularly designed for making small rope. The bobbin-holders *a a a* are rotated in a vertical plane by bands, and the bobbins are turned by the unwinding of the strands

Fig. 4445.

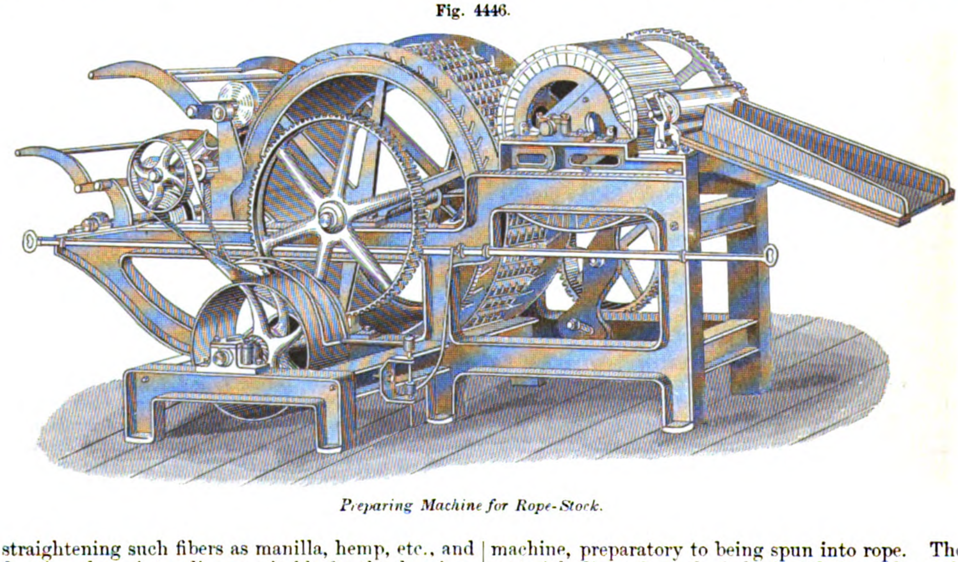


Rope-Machine.

b b b; these are laid together and twisted by the revolution of the reel *c d*, on which the completed rope is wound. This is driven by a pulley *e*, receiving its motion by belting from a drum on the same shaft by which the bobbin-carriers are actuated.

Fig. 4446 is a preparing machine for opening and

Fig. 4446.



Preparing Machine for Rope-Stock.

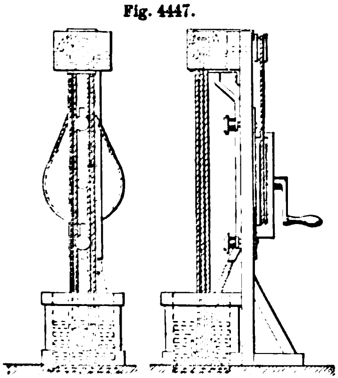
straightening such fibers as manilla, hemp, etc., and forming them into slivers suitable for the drawing-machine, preparatory to being spun into rope. The material, direct from the bale, is fed from the rack

on the left of the machine to the large-toothed cylinder, by which it is combed out, and, being taken off by the smaller slatted cylinder, is transferred to two rollers by which it is compressed into a sliver and delivered into the trough at the right.

Rope-por'ter. A light, two-wheeled carriage employed in the Fowler system of steam-plowing to carry the rope clear of the ground. See STEAM-PLOW.

Rope-pump. A water-elevator, consisting of a rope or ropes or of a fibrous webbing, whose lower end dips in the water which is discharged at the upper end, partly by centrifugal force, and partly by

Fig. 4447.



Rope-Pump.

the compression of the rope on the roller. The water is retained in the rope by capillary action. Such a one was used at Carisbrook Castle, Isle of Wight, England.

Rope-rail'way. A railway on which the cars are drawn by ropes wound upon drums rotated by stationary engines. This is frequently done on inclined planes in mining districts, and is sometimes adopted as a temporary expedient pending the construction of grades of lesser slope. See INCLINED PLANE.

The London and Blackwall Railway, for passengers and freight, was formerly operated in this manner by an engine at each end of the line. Arrangements were provided for detaching each car just previous to arriving at its desired station, so that its momentum would carry it to the proper point. The length of rope required was $6\frac{1}{2}$ miles, double the length of the road. Wire rope was found best; but the system was finally abandoned for locomotive power.

The ropes were connected to the drums by friction-clutches. The drums were of cast-iron, 23 feet in diameter, and their circumference revolved at the rate of about 26 miles an hour.

The rope was $5\frac{1}{4}$ inches in circumference, weighing about 40 tons; and to obviate the power required to drag this heavy weight at high speed, Mr. Elijah Galloway suggested the employment of two sets of wheels of different diameters, around each of which ropes, extending the length of the track, were to be wound: that passing around the larger outer wheel to be kept stationary at each end, while the other traveled as usual; it would thus cause the wheel to move at a much faster rate than itself, the ratio being as the diameter of the larger to the difference between it and the smaller.

One of the stationary engines of the Blackwall Railway was afterward set up in the City Flour Mills, Upper Thames Street, London, where it drove 32 pairs of stones, grinding 20,000 bushels of wheat per week. It is on the marine principle, and has 7 smoke-consuming furnaces. When one fire has just been fired up, the smoke is discharged into the adjoining fire.

Rope-trac'tion Pro-pel'ler. A mode of propulsion adopted with canal-boats to avoid the swell raised by paddles. A rope is laid along the bottom of the canal, and is wound upon a drum driven by the engine on board the boat. The rope passes back into the water over the stern of the boat, and may be picked up again and used by another boat following in the same direction.

The Chinese or differential pulleys have been inverted and used for this purpose, when a light vessel is to be propelled at a high velocity. See TOWING.

Rope'walk. A ground where ropes are made. Its length is estimated in fathoms, and is from 100 to 200 fathoms. At one end is the *spinning-wheel*, which rotates the *whirlers* to which the ends of a bunch of hempen fibers are secured, to be twisted into a *yarn*. Along the length of the walk are horizontal cross-bars with hooks, over which the yarns are swung as the men recede, walking backward from the *whirlers* and paying out the yarn.

A *laying* walk is one in which *yarns* are laid up into *strands* to form a rope. See ROPE-MAKING.

Rope-winch. A set of three whirlers driven by a strap and twisting three yarns which are to be laid up into a rope.

Rope-yarn. A single yarn composed of fibers twisted right-handed; used on shipboard for various purposes. Two or three twisted together form *spun-yarn*.

The size of a strand, and of the rope of which it forms part, is determined by the number of rope-yarns in it.

Rop'ing-nee'dle. (*Nautical.*) A heavy needle for sewing a sail to its bolt-rope.

Ro'sa-ry. A string of large beads representing an equal number of prayers, used by some religious sects. A bead is slipped through the fingers at each repetition of a prayer, until all or the specified number have been recited.

In the rosaries used by Roman Catholics, the beads representing the "Our Fathers" are larger than those for the "Hail Maries."

They are made of various materials, — dried berries, wood, ivory, metal, etc.

The Buddhists have for more than 2,000 years used long rosaries to keep count of their prayers. They also use the beads as counters for other things, and it is probable that the *chaplet*, twice as old as the Italian *rosary*, is the germ of the ABACUS (which see). See also PRAYING-MACHINE.

Rose. 1. (*Lock.*) The annular scutcheon round the spindle of a door-lock.

2. (*Hydraulic Engineering.*) A perforated cup or nozzle acting as a strainer at the induction of water into a pump, or at the nozzle as a means of dividing the water into fine streams for sprinkling.

3. (*Steam.*) The perforated nozzle of the injection-pipe, distributing the injection-water in jets or spray throughout the interior of the condenser.

Rose-cut. (*Gem-cutting.*) A mode of cutting gems in which the back is left flat and the face is cut into a series of inclined triangular facets arranged around a central hexagon. It is adopted for thin stones. See CUTTING GEMS.

Rose-di'a-mond. The *rose-diamond* is flat below, and its upper surface has 24 triangular facets. The center has a hexagonal arrangement, and the base of each triangle is joined to another whose apex touches the margin. The intervening spaces are cut into 12 facets in two zones. The upper or projecting is the *crown;* the lower portion, the *teeth*. See DIAMOND.

Rose-en'gine Lathe. (*Engraving.*) A lathe in which the rotatory motion of the lathe and the radial motion of the tool combine to produce a variety of curved lines. The mechanism consists of plates or cams set on the axis of the lathe, or suitably rotated and formed with wavy edges or grooves which govern the motion of the cutting point toward or from the center.

In another form, the combined radial and rotary motion is inherent in the work, the tool being stationary. In this case, the center of the circle in which the work revolves is not a fixed point, but is made to oscillate with a slight motion while the work revolves upon it.

The mandrel upon whose end the work is chucked does not rotate in stationary standards like those of a common lathe, but the standards form part of a frame which oscillates upon a horizontal axis below the bed and parallel to the mandrel axis.

The work is fixed in a chuck at the extremity of the mandrel, and the tool is held by a slide-rest, and adjusts it to the radius of the rose or figure intended to be cut. The oscillating motion is given to the mandrel by means of metallic rosettes or wheels fixed upon the mandrel, each having its edge or periphery indented and curved with a waving line. The rosettes are acted upon by a small roller at the end of a bar supported from the bed. As the mandrel revolves, the wavy periphery of the rosette is applied to the roller, which moves on a stationary axis and causes a vibratory motion of the mandrel as its frame moves to and fro on its axis.

The mandrel contains a number of rosettes of different patterns, and the governing roller is slipped on its axis so as to act in conjunction with any one of the rosettes, according to the pattern required.

Rose-engines and *geometric lathes* vary somewhat in their details, but agree in the general features that the work is performed by a combined rotary and radial motion. If the center of the rosette and the axis of rotation coincide, and the tool receive an oscillation radial as to the said center, a wavy circle is produced. If the chuck and its mandrel, while rotating, are oscillated back and forth on a parallel axis (as previously stated) while the tool is stationary, the same effect — a wavy circle — is produced; the change merely being to move one part or the other, relatively to its fellow, in the degree and proportion. If the center of the pattern do not coincide with the axis of the mandrel, the effect will be an eccentric figure. If the radial oscillation be given to tool or chuck, in addition to the former conditions, a wavy eccentric figure will be produced. (See CHUCK; ECCENTRIC.) If an oval or elliptical pattern be required, it may be obtained by means of an eccentric guide or ring of brass fastened to the puppet of the lathe close to the collar in which the neck of the mandrel runs. (See CHUCK; OVAL.) If the governing eccentric be wavy, the effect will be a wavy ellipse. By governing squares or other geometric figures, patterns of the required conformation are obtained. By a suitable disposition of the parts involved in the circular and radial motions, the tool is caused to make the peculiar line required within the limits of the said figure. By means of a *straight-line chuck*, the patterns of a rose-engine are made to follow in a straight instead of a circular direction.

Notable instances of the uses of this class of instruments are to be found in the machines of engine-turning watches, and those for making the complicated figures termed *lathe-work*, which abound on the obverse and reverse faces of greenbacks and other bank-notes.

Rose Gas-burn′er. A burner giving a circle of small flames. See STOVE-BURNER.

Rose-lash′ing. (*Nautical.*) A kind of lashing or seizing employed in woolding spars. So termed from its form.

Rose-nail. A nail with a conical head which is hammered into triangular facets. See NAIL.

Rose-steel. A kind of steel of cementation whose interior part exhibits, when fractured, a different texture from that of the exterior.

Ro-sette′. 1. (*Metallurgy.*) A disk of red copper from the refining hearth or crucible. As the impurities are removed in the shape of scoriæ or slag, and the metal exposed, the surface of the metal is congealed by throwing on water. This is called *quenching*. The hardened crust is of a red color, and is called a rosette. The operation being repeated, the metal is obtained in a form for ready handling and farther treatment, instead of being in a solid mass. It is known as *rose-copper*. See COPPER-FURNACE.

2. (*Mill.*) A circular arrangement of sails in a windmill; the vanes attached to radial arms.

3. A leather or metallic ornament placed on a bridle or halter at the point where the front joins the crown-piece.

4. A circular ornament of fabric, plaited with leaves somewhat resembling those of a flower.

5. (*Gas.*) A form of gas-burner in which the gas issues at a circular series of holes resembling a rosette. See STOVE-BURNER.

Ross′ing-ma-chine′. 1. A machine for removing the *ross*, or rough, scaly, exterior portion of bark, from the remainder.

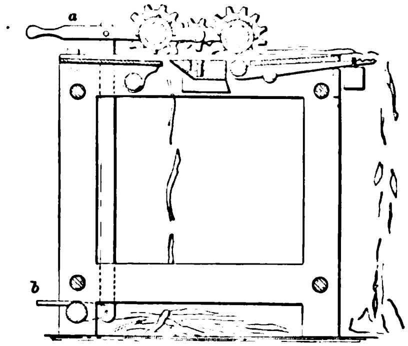
2. A machine for removing bark from logs in advance of the saw. The bark, containing much silex and sometimes grit, soon dulls the saw. See Fig. 4451.

3. A machine for cutting up bark for steeping or boiling. The vegetable extract is used for tanning, medicine, dyeing, etc.

In the most correct sense, the removal of the outer cuticle, there are several processes.

By pressure against a splitting-knife. An example is shown in Fig. 4448, in which the bark is fed along a table and beneath cogged pressure-rollers

Fig. 4448.

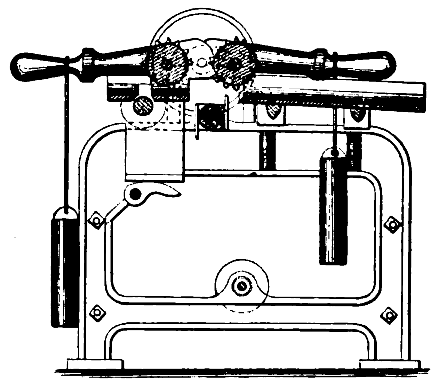


Rossing-Machine.

which carry it against the stationary knife, which is adjustable in hight, so as to take off such a thickness of *liber* as may be desired. The required pressure of the feed-rollers is given by means of levers *a* actuated by treadle *b*.

In a modified form (Fig. 4449), the bark is fed beneath pressure-rollers while its *liber* is planed therefrom by a revolving cutter. The pressure on the rollers is given by the weights suspended from the levers.

Fig. 4449



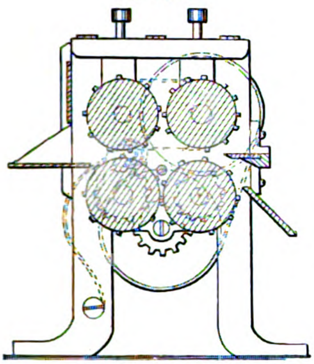
Rossing-Machine.

In Fig. 4450, an idle roller placed between the upper edges of the lower rollers facilitates the passage of the bark. A knife is placed between the rear edges of the upper and lower rollers, and presents a cutting edge to the bark as it comes from the rollers.

A common use of the *rosser* is in saw-mills, where it is used to remove the bark from the log in advance

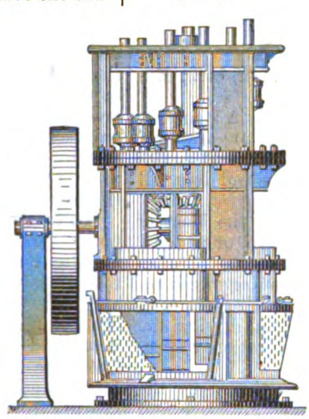
of the path of the saw. This is to save the saw-teeth from being dulled by the bark.

Fig. 4450.



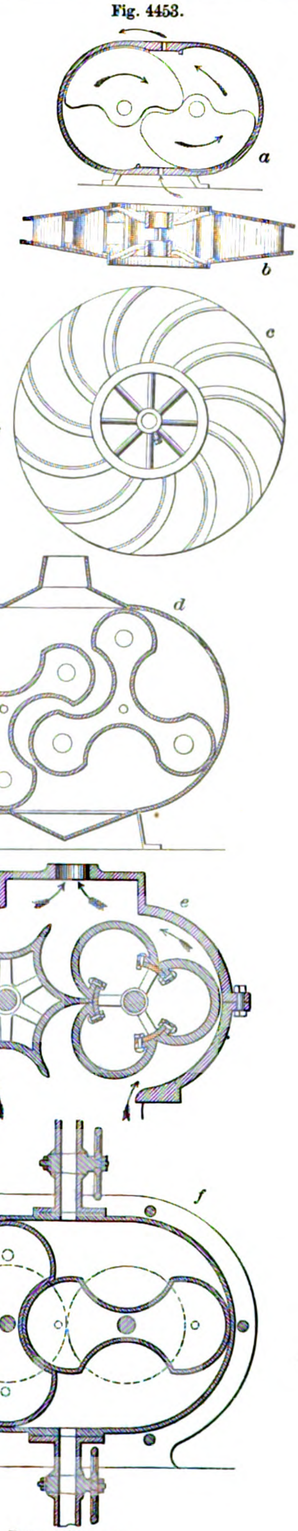
Bark-Planing Machine.

Fig. 4452.



Rotary Stamp-Battery.

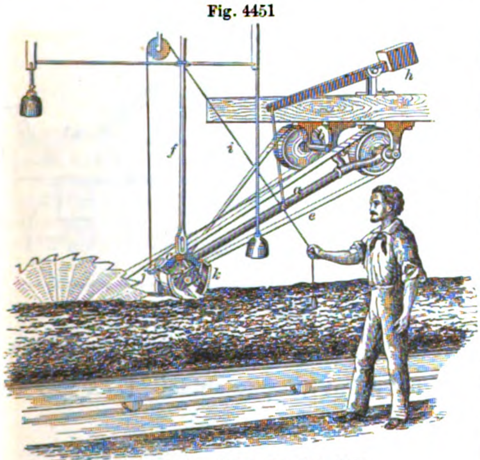
Fig. 4453.



Rotary Blowers.

Stearns's machine (Fig. 4451) consists of an arm *a* fastened to the bearings *b*, so that it swings freely thereon. At the other extremity of the same arm is a disk *c*, carrying a pulley, and a revolving cutter-head *d*. These cutters are driven by a belt *e*, at a high velocity. The disk *c* has an upright rod *f* attached, by which the action of the shields *k* is controlled, they being inclined on one side or the other as the rod *f* is diverged from a

Fig. 4451



Rossing Attachment for Saw-Mill.

straight line. These shields guide the cutters. The arm *a* is counterbalanced by a weight *h*, so that it is easily raised, by drawing on the line *i*, one end of which is attached to a lug *j* on the arm, and the other passes over pulleys to the workman's hand.

The shields *k* raise the cutters while in action, to suit any rough places or knots that may be on the logs by them.

Rost'horn's Gun-met'al. An alloy composed of 55.04 parts copper; 42.36 zinc; 1.77 iron; and 0.83 tin; or, according to another analysis, 57.63 copper; 40.22 tin; 1.86 iron; and 0.15 tin. See table on page 61.

Ros'trum. 1. (*Surgical.*) A crooked pair of forceps with beak-like jaws.

2. The *beak* of a still, connecting the *head* with the *worm*.

3. (*Nautical.*) The prow or beak of a vessel.

4. The elevated platform or stage in the forum of ancient Rome, from which the orators addressed the people. A platform in a hall or assembly.

Ro'ta-ry. Having a motion on its axis, as a wheel (Latin, *rota*), a ball, etc. The words *rotary*

and *revolving* are needed in their peculiar spheres, and should not be confounded.

Rotation, as of a planet on its axis.

Revolution, as of a planet in its orbit.

See ROTARY PUMP; ROTARY ENGINE, etc.; REVOLVING-CYLINDER ENGINE, etc.

Ro′ta-ry Bat′ter-y. (*Metallurgy.*) A stamping battery for crushing ores. The stamps are arranged circularly around a vertical shaft, which carries around an inclined plane that raises and lets fall each stamp in succession.

Ro′ta-ry Blow′er. One in which the blast of air is obtained by the rotation of a piston or pistons, or of a fan.

a (Fig. 4453) is a form in which two segments revolve in a case in different directions, their surfaces in contact; the segments act alternately in driving air.

b c are a sectional view and side elevation respectively of a fan-blower.

d is a three-head piston-blower acting upon the principle of *a*, but having a larger air-space and heads which act in succession and alternation.

e has pistons of varying shape, having concave and convex abutting surfaces respectively.

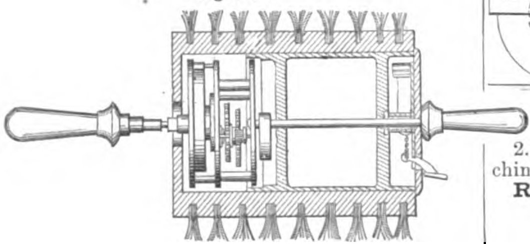
f is a double-headed blower.

It will be seen that in *a d e f* the pistons are of such shape as to pack against the case, and also against their fellows, so that no air may leak around them or between them. See also BLOWER; FAN.

Ro′ta-ry Brush. A cylindrical brush turning on an axis. A kind employed by hair-dressers is turned by an elastic belt suspended from a pulley overhead, and the ends of the axis terminate in handles by which it is manipulated.

Another (Fig. 4454) has an interior helical spring, which is wound up by means of one of the handles, and actuates a train of clock-work, causing the

Fig. 4454.

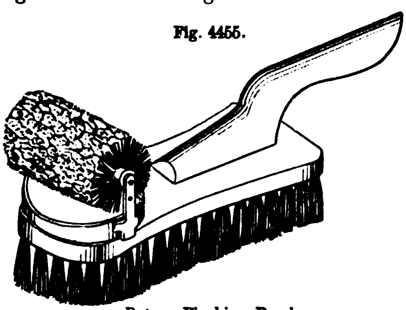


Rotary Brush.

brush to rotate; a brake is provided for checking or stopping its motion.

Fig. 4455 is a blacking-brush in which a rotary

Fig. 4455.

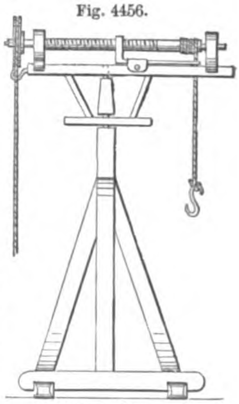


Rotary Blacking-Brush.

cylinder at the back serves the purpose of the ordinary dabber in laying on the blacking.

Ro′ta-ry Crane. One swinging on an axis, so as to present the jib in any direction to lift or deposit the load. In the example (a crane for light purposes), the barrel shaft has a screw thereon, which engages the sliding guide, to coil the cord fairly upon the barrel. See CRANE.

Fig. 4456.

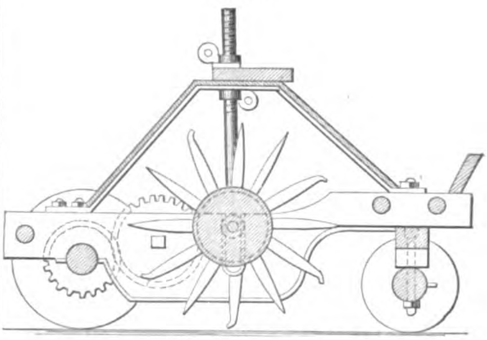


Rotary Crane.

Ro′ta-ry Cul′ti-va′-tor. (*Husbandry.*) A digging implement with rotary spades which pierce and lift the soil. The shaft of the rotary digger is suspended by screw rods from the bridge of the frame, and is rotated by gearing from the ground-wheel. See DIGGING-MACHINE.

Ro′ta-ry Cut-ter. 1. (*Metal.*) A toothed disk on a mandrel, between the centers of a lathe. Used in cutting gears, milling, etc.

Fig. 4457.

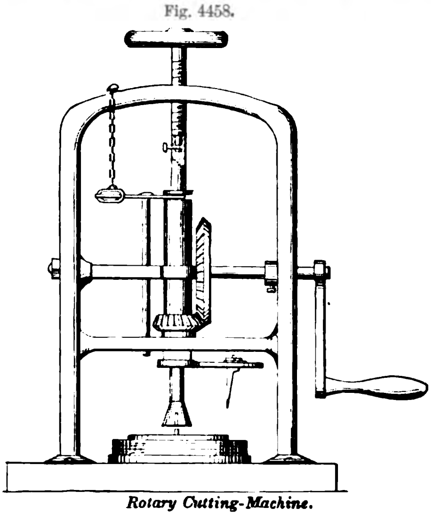


Rotary Cultivator.

2. (*Wood.*) A cutting head in a planing-machine.

Ro′ta-ry Cut′ting-ma-chine′. 1. A tool for

Fig. 4458.



Rotary Cutting-Machine.

cutting an annular hole or kerf. A *crown*, *trephine*, or *cylindrical saw*, or an *annular auger* (which see).

In the example, the middle mandrel acts as a holder when the screw is turned; the sleeve is driven by the gearing, and has a cutter which is adjustable radially to regulate the diameter of the circular pieces of paper cut thereby.

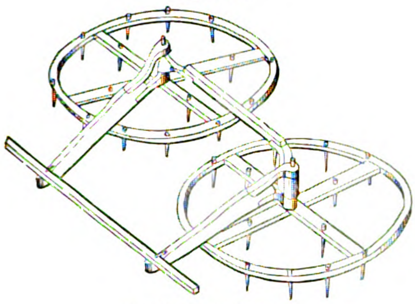
Ro'ta-ry Dig'ger. (*Husbandry.*) A machine with rotary spades. See pages 703, 1068. See also ROTARY PLOW.

Ro'ta-ry En'gine. See ROTARY STEAM-ENGINE.

Ro'ta-ry Fan. (*Pneumatics.*) A blowing-machine with rotary vanes. See ROTARY BLOWER; BLOWER; FAN, etc.

Ro'ta-ry Har'row. (*Husbandry.*) One having the tines set in a frame which rotates on a vertical axis as the harrow is drawn along the surface of the

Fig. 4459.

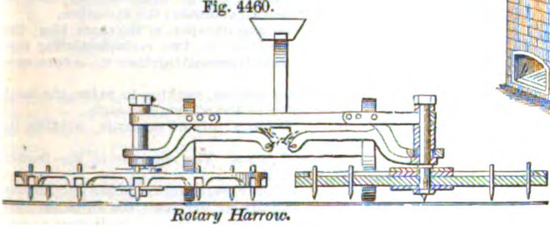


Double Rotary Harrow.

ground. In the example, the bent rim and the spokes have teeth, and their axial pin is journaled in bearing sleeves attached to the draft-bars. The cranks of the rotary harrows are connected by a transverse bar.

The circular tine-frames are so hung to the frame

Fig. 4460.

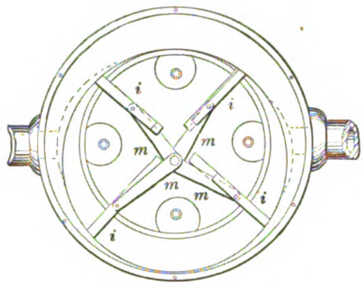


Rotary Harrow.

as to rotate on their axes when dragged upon the ground. This motion is sometimes produced by hanging them eccentrically, so as to have a greater resistance on one side than the other.

Ro'ta-ry Me'ter. One in which the measuring device or piston rotates in a case. It resembles in construction the ROTARY PUMP or ROTARY STEAM-ENGINE (which see), but has a vessel or passage of known capacity, and the revolutions of its piston are registered. In Fig. 4461, the inner cylinder is eccentric, and has radial pistons *i* connected by links *m* to a wrist that forms the center of motion, around which the pistons revolve. A fixed crank is thus dispensed with, and the parts accommodate themselves to conditions incident to expansion and contraction from changes of temperature. The heads of the revolving cylinder work in recesses in the case of the engine, so as to prevent friction and wear upon the pistons. See SPIRIT, GAS, WATER METER.

Fig. 4461.



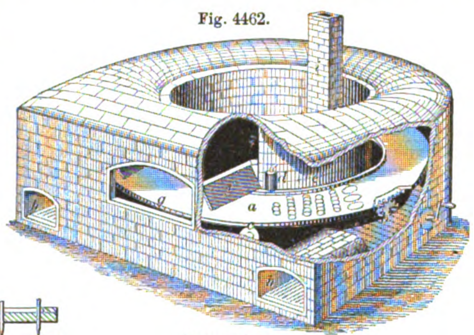
Rotary Meter.

Ro'ta-ry Ov'en. One in which the bread-trays or bread-tables rotate, so as to receive the dough at the oven door, carry it in a circuit around the oven, and present it at the delivery door, the rate of progression being so timed and the heat so regulated as to accomplish the baking during the circuit.

There are two principal varieties of rotating ovens; those in which the circular bread-table rotates on a vertical axis, and those in which the bread-trays are suspended from the arms of a reel which has a horizontal axis: the latter is known as a *reel-oven*. See OVEN.

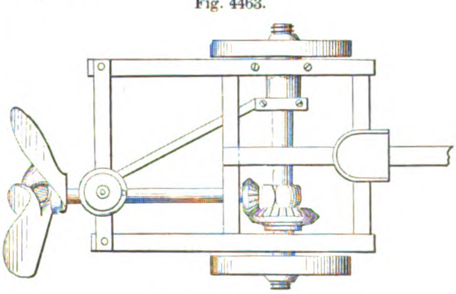
Wedge's rotary oven has an annular plate *a* rotated by a pinion *b* operated by a hand-crank or machinery, and sustained on friction-rollers *c*; other friction-rollers *d* prevent it from bearing against the interior masonry *e*. Swinging damper-doors *f* prevent the escape of heat. These are kept constantly closed when baking crackers. The dough is introduced and removed, when baked, through the door *g*. *h h* are the furnaces, from which the products of combustion pass to the chimney *i* through circulating flues.

Fig. 4462.



Rotary Oven.

Fig. 4463.

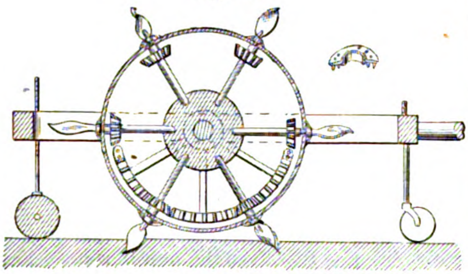


Rotating-Share Plow.

Ro′ta-ry Plow. (*Husbandry.*) A plow with rotary share. In Fig. 4463, it is in the rear of the frame and is driven by gearing from the driving-wheel axle.

In Fig. 4464, the segmental driving cog-wheels connect with supplementary yielding cogs attached with springs. The segmental wheels rotate the earth augers only when in contact with the earth. The yielding cogs insure the meshing of the auger pinions with the rigid cogs of the segmental gears. See also pages 703, 1068.

Fig. 4464.



Rotary Plow.

Ro′ta-ry Pud′dler. (*Metallurgy.*) An apparatus in which iron is puddled by rotary mechanism instead of by hand labor. The idea is believed to have occurred to Henry Cort, but the first practical attempt to execute it appears to have been made by Yates and Tooth, who constructed a furnace having a rotating trough, with fixed rabbles through which a current of water was conducted to prevent them from melting, which, however, it did not effect. The Bromhall puddler was arranged with four rabbles, which were caused to assume different angles, as they were drawn over the bed of the furnace. Subsequently, Mr. Menelaus, manager of the Dowlais Works, contrived a cylindrical rotary furnace, in which the puddling was effected by the rotation of the furnace alone. This was not successful in practice, owing to the great expansion and contraction and the rapid destruction of the lining.

About 1867, Mr. Danks of Cincinnati developed the first practical rotary puddling-furnace. This has since been greatly improved, and has been, to some extent, introduced into Great Britain and the Continent of Europe. See PUDDLING-FURNACE.

Ro′ta-ry Pump. One whose motion is circular. The kinds are various ; in some the cylinder revolves or rotates, as the case may be, moving in a circular path or rotating on its own proper axis. Some of these are considered under CENTRIFUGAL PUMP (see pages 514–516). The more common form of rotary pump is that in which the piston or pistons rotate on an axis, as seen in the illustrations, Fig. 4465.

a is a double-wheel pump from the old collection of Sérviere. The cog-wheels rotate in contact with each other, the teeth of each filling the interdental spaces of the opposite. Sérviere was born at Lyons, 1593. See also Ramelli's book, sixteenth century.

b is Eve's rotary pump, 1825. It has three pistons on a hub, and a rotating abutment, which offers a depression to enable the pistons to pass as they are successively presented.

c has a hub with one piston, and a curved flap which turns on a hinge.

In *d* the pistons are cam-shaped, and the vertical valve which forms the abutment rises on the cam, and then shuts down behind it, to rise again on the next cam.

e has a sliding valve which is operated by exterior devices and recedes to allow the piston to pass.

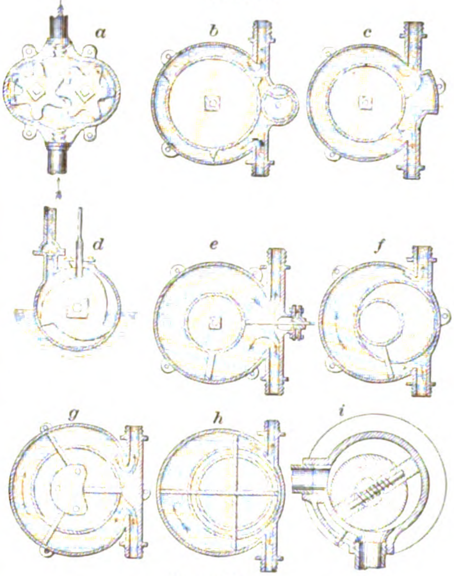
f has two concentric drums, the annular space for the water being traversed by a piston which consists of a rectangular piece of brass driven by a revolving eccentric cylinder, which at the same time forms an abutment.

g has three pistons, which move radially in a circular shell, which rotates in contact with the segment on the case, forming the abutment. A D-cam actuates the pistons.

h has a rotary hub eccentric with the case, and two pairs of pistons acting in diametric slots.

In *i* the hub is similarly placed, but has one pair of spring pistons, in a single diametric slot.

Fig. 4465.



Rotary Pumps.

In *j* (Fig. 4466) the annular piston is moved eccentrically around inside the cylinder. The convex-faced valve is supported on a spring arm and follows the movement of the cylinder, so as to form a continued separation between the induction and eduction passages.

k, Leuchtweiss's pump, has four pistons and an abutment-wheel with four depressions, traversed by the pistons in turn.

l is Andrew's pump, having a pair of segment-cams, each of which is a driver, and forms an abutment for the other.

m, Hardy's pump, is an amplification of the same idea, the double-headed pistons revolving in two communicating segments of cylinders, and being geared together to secure uniformity of rotation.

n is Bazin's three-headed pistons, working in pairs, the head of one filling the depression of the other alternately.

o is Behren's pump. It has a pair of segments, working on the same principle as *l*.

p is Vialon's centripetal pump. The converse of the Barker mill. See Fig. 562, page 231

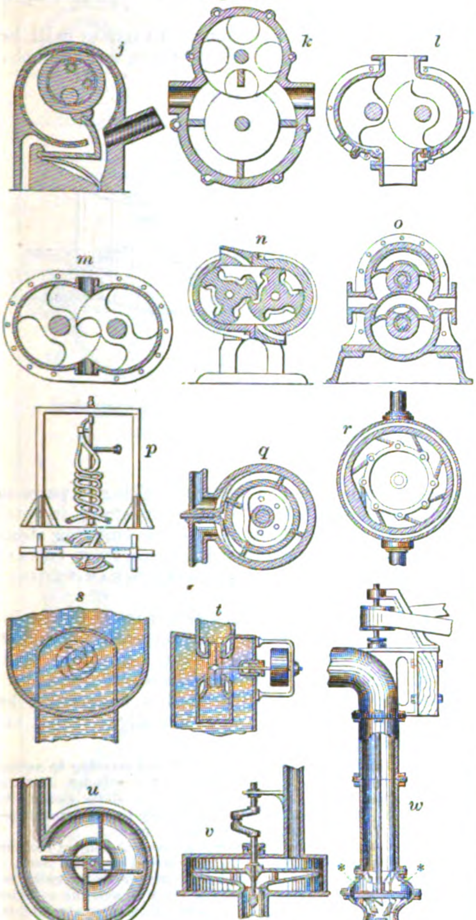
q is a form shown in an old French work. It has four pistons which slip in and out radially, as they pass the abutment between the induction and eduction ports. The stationary eccentric allows them to be pressed in as they come against the incline, and again forces them out after passing the abutment.

r has a number of hinged pistons arranged on the periphery of the hub. As each one approaches the double inclined plane forming the abutment, it is pushed in against the hub, and when it has passed the crest of the rise is opened again by a spring beneath it.

s t are two views of the Appold rotary pump, which has a series of wings on a horizontal shaft revolving in the water. The views are vertical sections taken in planes at right angles to each other. This pump has been largely used in England in wrecking and drainage.

With a hollow cylinder 12 inches in diameter by 3 inches deep, to which a rotation of 800 times a minute is given by a steam-engine, this machine can raise 1,800 gallons of water per minute to a hight of 10 feet. In November, 1851, one of these pumps was set to work to assist in draining Whittlesea Mere. The cylinder was 4½ feet in diameter, and was immersed in one of the channels or cuts by which the Bedford level is intersected. The average velocity is 90 revolutions or 1,250 feet per minute. A double-cylinder steam-engine was erected upon the spot, and its power was applied to drive the pump. The steam pressure was 40 pounds per square inch, and the vacuum 13½ pounds ; the lift, 5 feet. An immense volume of water, no less than 16,000 gallons per minute, was raised by this means, all of which passed through the cylinder of the machine, and was

Fig. 4466.



Rotary Pumps.

carried off by a channel prepared for it. One of Bessemer's pumps, with a cylinder 9 feet in diameter, has raised as much as 200 tons of water per minute by the aid of a 30 horse-power engine. This pump is shown at *v*, Fig. 4466.

The *Massachusetts centrifugal pump* (*u*), shown at the London World's Exposition, has a short horizontal shaft, carrying a square boss with 4 tangential blades, which rotate within a metallic case having axial induction and a tangential eduction. The pump is submerged, and is driven by gearing and shafting.

Gericke's rotary pump is shown at *w*. The vertical shaft carrying the wheel is driven by a band on a pulley above. Above the wheel are a series of curved guides ** to direct the water to the center of the chamber at the foot of the vertical stand-pipe. A fixed plate is placed above the wheel, and forms the floor of the ascension chamber, the water being driven around its margin by the centrifugal power of the wheel.

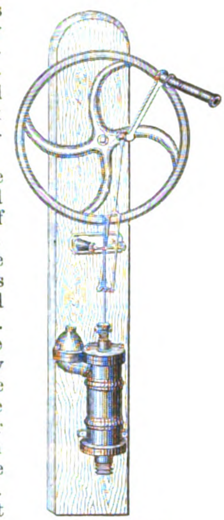
See also CENTRIFUGAL PUMP.

Fig. 4467 is a (so-called) rotary pump. All that is rotary about it is the wheel, on which are the hand-crank and the wrist to which the pitman is attached.

Ro'ta-ry Shap'er. A machine for planing, turning, and slotting.

Van Haagen & Co.'s has a table *a* at front, which is caused to move vertically by means of an upright screw receiving motion by gear connection with a horizontal shaft provided with a crank *b*, so that it may be operated by hand when desired.

Fig. 4467.



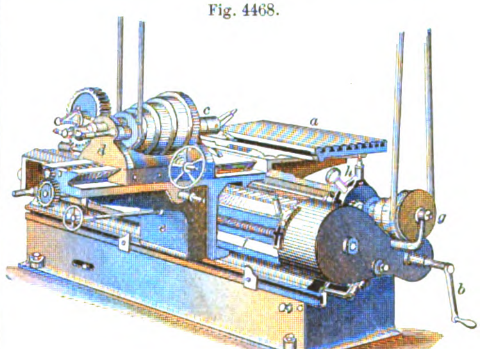
Rotary Pump.

The tool-spindle *c* may be moved both transversely and longitudinally by means of the head-stock *d* and slide *e*. The latter is operated by the feed-screw *f*, which derives its motion, through concealed gearing, from the shaft *g*. By means of a shifter *h*, the motion of the gearing may be changed so as to reverse the direction, both of the slide and table, either or both of which can be thrown out of connection with the shafter and worked by hand. For reversing the movement of the slide *e* in planing, adjustable lugs are attached to the inner part of the shaft, which are struck alternately by the slide *e*, throwing over the shifter *h*; a semi-rotation is automatically imparted to the tool-holder at the same time.

For horizontal drilling, the head-stock alone is advanced toward the work, either automatically or by hand.

In slotting and in cutting the teeth of wheels, a rotary tool is used, the table and head-stock being

Fig. 4468.



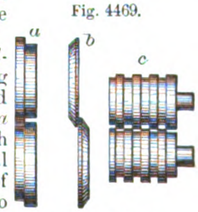
Rotary Shaper.

moved to suit the character of the work by hand or by the self-acting devices.

By the employment of suitable tools, the interior of steam-cylinders, pulleys, and similar work may be turned out, and key-seats cut in pulleys without moving the work after turning.

Ro'ta-ry Shears. (*Metal-working.*) A shears for cutting metal, having rotating instead of reciprocating blades. In *a* (Fig. 4469), the face of each blade has two steps; the metal is sheared between the angles of the prominent faces of the two disks.

Fig. 4469.



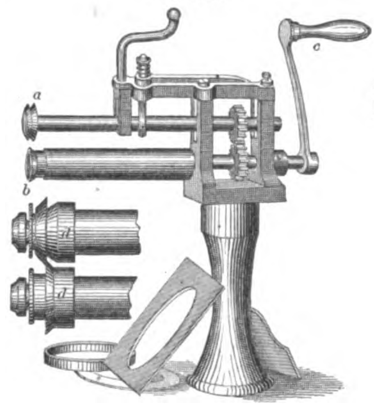
Rotary Shears.

b is better adapted for thin sheets.

c consists of two rollers, each having rectangular annular projections which fit corresponding grooves in the other, enabling a number of strips to be cut from a sheet at once.

In Fig. 4470, the shafts carrying the cutters *a b* are geared together and turned by the handle *c*. The cylindrical portions, shown at *d d* on an enlarged

Fig. 4470.

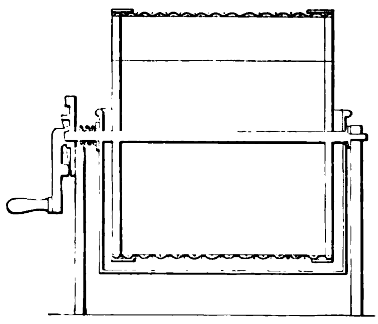


Rotary Shears.

scale, serve to guide and hold the plate to the shears. The distance between the two cutters is regulated by raising or lowering the upper shaft. The machine is designed for cutting plates too thick to be conveniently severed by the ordinary bench-shears.

Ro'ta-ry Sift'er. A cylindrical sieve. It has a segmental opening for the introduction of meal. The hand-crank has a projection which runs on in-

Fig. 4471.



Rotary Sifter.

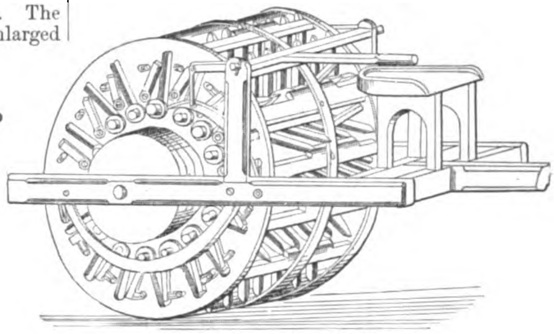
clined abruptly-terminating cams upon a circular disk, which serve, in combination with a spiral spring, to shake the sifter longitudinally. See ASH-SIFTER; SIEVE; SCREEN; RIDDLE, etc.

Ro'ta-ry Spad'er. A digger having on a drum or frame a series of spades brought successively to the ground. In Fig. 4472, when the spades are ready to enter the ground, by the rotation of the cylinders, they are in nearly a vertical position, and are held down by one of the latches, remaining in the same position until the cylinder has passed over them, causing the earth to be broken up and overturned. See also pages 703, 1068.

Ro'ta-ry Steam-en'gine. One in which the piston rotates in the cylinder or the cylinder upon the piston.

The varieties are numerous. Examples will be given of engines with one, two, three, and four pis-

Fig. 4472.



Rotary Spading-Machine.

tons on single axes; of pistons working in pairs on several axes; of wheels driven by steam injected against them, or working by reaction, emitting steam tangentially. For another kind, see DISK STEAM-ENGINE. See also BREAST-WHEEL STEAM-ENGINE; REACTION STEAM-ENGINE.

Rotary engines were suggested or made by the inventors of the last century and the early portion of the present. The names of Watt, Cartwright, Galloway, and others may be mentioned.

The illustrations will be readily understood by reference to Plate LIII., with but slight verbal explanation.

a has a single piston keyed to the hub and rotating in an annular chamber, which has the function of a cylinder. In the middle, on the right, is the abutment which slides radially to allow the piston to pass. Above and below the abutment, respectively, are the induction and eduction ports.

b has a single piston which passes a crescent-shaped rocking abutment situated between the induction and eduction ports.

c. The piston revolves on a hub concentric with the cylinder, and the annular steam space between the hub and the cylinder side is traversed on each side alternately by sliding abutments, connected together and operated by a segmental cam on the piston-shaft, which impinges against anti-friction rollers of the frame.

d. The steam issues from the piston at *, and is educted at ×, passages being provided through the tubular shaft. The abutments swing out of the way for the passage of the piston, being actuated by connecting rods and levers operated by a cam on the main shaft.

e. The piston-wheel is arranged eccentrically within the cylinder, and has two buckets, which are expanded radially by springs, and withdrawn to pass the abutment by contact with the cylinder. Packing segments on the piston-wheel and the edges of the buckets confine the steam.

f has an elliptical piston, the working faces of which are expansible by screws to pack it against the inside of the annular chamber in which it revolves. It has a rocking abutment which oscillates in a chamber.

g has two pistons with vibrating abutments, which retract into recesses to allow the pistons to pass.

h. The pistons are situated upon the extremities of the hollow arms; the steam ports in the hub of the main shaft serve as induction passages for the steam, the eduction ports being located upon the periphery of the inclosing case of the engine. The steam is admitted to a chamber in the shaft through a pipe which revolves therewith.

j has three pistons, which have a certain freedom of motion in seats in the inner cylinder, which rotates in an eccentric drum.

k has three pistons on a wheel keyed to the main shaft. Inclines on the advancing faces of the pistons push back the swinging abutments, which then close the eduction. The induction ports are above and below.

l has three pistons, two valve-abutments, and two induction and eduction ports respectively.

m has three pistons on one shaft, set at angles of 120°. Steam admitted at one side of the casing and departing at the other presses against a flexible band which drives the pistons before it.

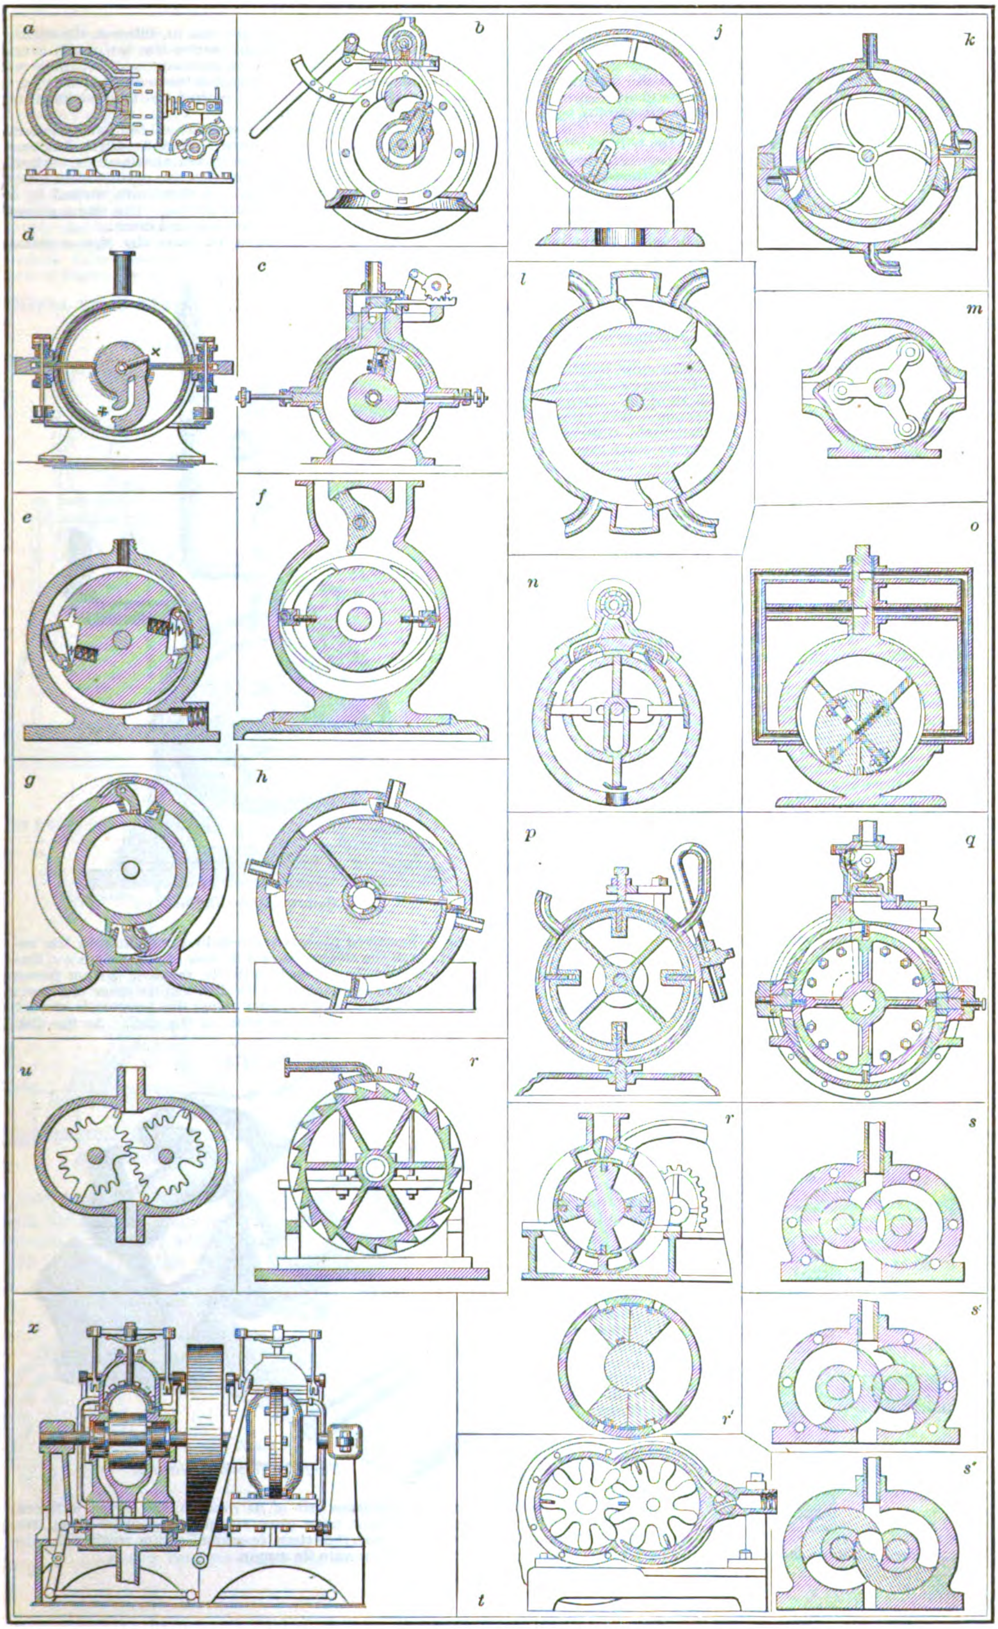


PLATE LIII. ROTARY STEAM-ENGINES. See pages 1990, 1992.

n. The eccentric hub revolves in the annular cylinder, and has pistons arranged on yokes, traversing at right angles to each other, and provided at their ends with spring packing-plates, which accommodate themselves to the interior surface of the cylinder. The induction openings are also covered with flexible plates, which accommodate themselves to the surface of the hub, and permit the passage of the piston. The engine runs in either direction and exhausts at the bottom.

o has also diametric pistons, which are equal to the diameter of the casing, and slip to and fro in slots in the eccentric hub.

p has four distinct pistons, which slip in and out in radial slots in the circumference of the eccentric hub. Steam is admitted and educted by flexible pipes. The abutment, as in the last two mentioned, is formed by the contact of the hub with the inside of the cylinder.

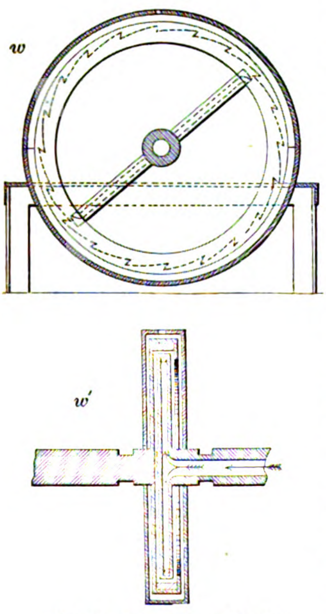
q is the Scheutz engine (Swedish), shown at the French Exposition. Its hub and cylinder are concentric, and the abutments are formed by double inclines, which force in the pistons as they come in contact therewith. Steam is introduced and discharged at ports leading through the inclines on the respective sides of the abutments.

r r′ are two views of another Exposition engine, by Thompson, of Edinburgh. There are two pairs of pistons, each attached to a core which occupies but half the length of the cylinder in the direction of its axis. Each pair of pistons is thus attached to its own core only for half the piston length, while the other half projects over the core belonging to the other pair. Neither pair of pistons can therefore pass the other, though they may come into contact. Each pair of pistons has its independent shaft, and externally to the cylinder each of these shafts carries an elliptical gear-wheel, which works into an equal and similar wheel upon a shaft parallel to the piston-shaft. This second shaft, which is the working shaft, has a fly-wheel regulator. Steam is admitted between the sector-shaped pistons, and the motion is produced by the preponderance of leverage at the time. See Dr. Barnard's Report, pages 87 - 93.

s s′ s″ are three views of Behren's Exposition engine, American. The views show three positions of the pistons which work in apposition. It has two cylinders, whose spaces overlap each other, and in the center of each is a solid cylindrical core. Each piston is firmly attached to an axis, and is part of a solid ring fitting to the core and to the interior of the cylinder. The axes are externally connected to gear-wheels to insure simultaneous and equal action. A portion of each core is removed to enable the opposite piston to pass. Steam enters above and discharges below. The pistons are alternately motors and abutments. In *s* the steam is just commencing to act on the left-hand piston. At *s′* the steam is acting on the right-hand piston. *s″* shows the position of the pistons when changing duty.

t is the Pillner and Hill engine, English, also shown at the French Exposition. It has two cylindrical overlapping chambers, and two systems of rotary pistons, which may be compared to cog-wheels. These wheels, by the close contact of their cogs, prevent the passage of steam between them, and they are adapted steam tight to the interior of their cylinders by metallic packing in the tips of their teeth. Practically, it is found to be sufficient to pack two teeth diametrically opposite to each other in each wheel.

Fig. 4473.



Harris's Rotary Steam-Engine.

u is a somewhat similar form, in which the two packing-teeth are alone prolonged to touch the interior of the cylinder; deep depressions in the opposite wheel allow these prolonged teeth to pass At intermediate points, shorter teeth gear into each other to prevent passage of steam at this point.

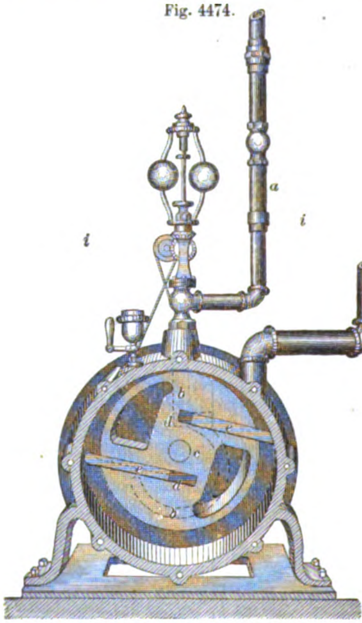
In *v* a jet of steam is forced against the vanes of a wheel as they are presented in turn in a steam-tight case.

Fig. 4473 shows two views of the Harris engine, in which the portions are attached to two hubs and run in different directions. One axis with hollow trunnions carries the two radial arms which emit steam at their ends, tangentially, and so run by reaction; the steam emitted acts against vanes on the other portion and drives it directly. By gearing, the two motions are utilized upon a single shaft.

In *x*, Plate LIII., the common shaft of the two cylinders carries a fly-wheel between them. This fly-wheel has cam grooves on its sides by which the piston abutment is worked. The pistons are so coupled together that one portion shall carry the other over the dead-centers. A slide-valve worked by a hand-lever enables reversion of the engine. The steam passes through the chambered piston-journals and drum.

In Fig. 4474, the steam admitted from the pipe *a* passes

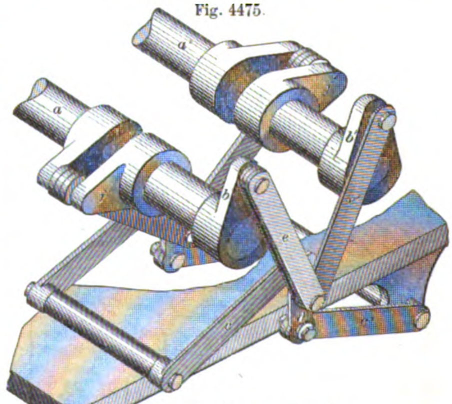
Fig. 4474.



Rotary Steam-Engine.

through the curved passage *b* (shown in dotted lines) in the rotary disk *c* to the steam spaces *d* in rear of the pistons *e e*, forcing each radially outward until its recessed portion passes partly beyond the periphery of the disk and its outer end rests against the surrounding cylinder, when the pressure is exerted circumferentially, causing rotation of the disk. As the disk

Fig. 4475.



Knight's Noiseless Gearing.

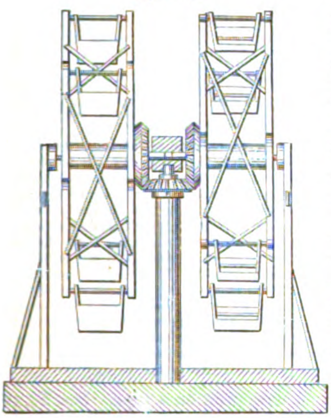
approaches the upper part of its rotation, the piston is forced in and the exhaust takes place, steam being cut off from this piston at the same time that the second piston reaches the induction port to receive its supply.

Knight's noiseless gearing (Fig 4475) is adapted for rotary engines employing paired shafts, for paired rollers, and in other cases where the co-rotation of two objects is desired, avoiding the friction and clattering of the usual modes of gearing.

In the illustration, *a a′* are the piston-shafts of a double-cylinder rotary engine; these have equally eccentric wrists *b b′* at their extremities. *c c′* are two equal arms hinged to brackets or other fixed objects, and having their other ends pivoted to a link *d*, which is pivoted to the two pitmen *e e′* connected to the extremities of the wrists *b b′*. To insure accuracy of movement, a second pair of wrists *f f′* at right angles to the first are formed on the shafts *a a′* and connected to each other by a precisely similar arrangement. The rotation of one shaft thus causes the other to rotate with equal velocity in the opposite direction. Other modifications are shown in George H. Knight's patent of September 10, 1867.

Ro′ta-ry Swing. The horizontal shafts with which the radial arms revolve have bevel pinions engaging the bevel-wheel on a pivot post, by which a horizontal revolution of the whole frame is effected.

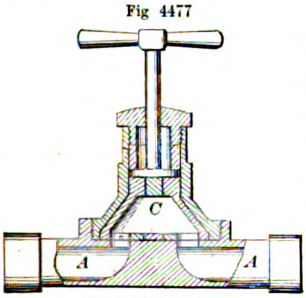
Fig. 4476.



Rotary Swing.

Ro′ta-ry Valve. A valve which acts by a partial rotation, such as the four-way cock or the faucets used in the Worcester, Savary, and early Newcomen steam-engines. The *trunnion-valves* of the oscillating-cylinder steam-engines have a reciprocating partial rotation. The valve has a passage *C*, which, when brought in line with the steam-pipe *A A*, connects the two parts of the same, and is adjustable, so that the passage may be completely or partially interrupted, as desired. When the passage is interrupted, the steam is made to press the valve upon the seat and thus prevent all escape, and makes a steam-tight joint without the use of packing.

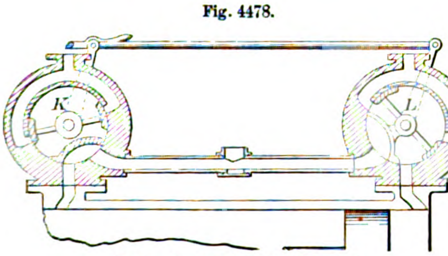
Fig 4477



Rotary Steam-Valve.

In Fig. 4478, the valves *K L* have each three wings; they oscillate in and coincide in form with the frustal chambers, whose ports connect with the steam-cylinder. The pressure on each valve is nearly balanced, and it is kept to its seat by a coil spring acting longitudinally on its stem.

Fig. 4478.



Rotary Valve for Steam-Engines.

Ro′ta-scope. An instrument on the principle of the gyroscope, invented by Professor W. R. Johnston of Philadelphia, about 1832. See GYROSCOPE.

Rot′ten-stone. A soft, brown mineral, found in Derbyshire, England, and used as a polishing material.

It is composed of alumina, 86; carbon, 10; silex, 4. It is sometimes called a variety of tripoli, but the latter is principally silex. Rottenstone is more nearly allied to emery, but has a portion of carbon and no iron. Iron is present in all the emeries.

Rot′ting. The steeping of flax-stalks to soften the gum and loosen the fiber from the woody portions. See RETTING.

Ro-tun′da. (*Architecture.*) A circular building or apartment covered by a dome, as the Pantheon at Rome, the large central apartment in the Capitol at Washington, etc. See also DOME.

Rouge. 1. A peroxide of iron of a light red color, used for polishing gold, silver, and speculum metal.

Sulphate of iron is purified of silex and calcined in a crucible. By restricting the heat to a dull red, the result is light-colored and forms *rouge*. If prolonged, black oxide is formed which gives it a cutting quality, and it becomes *crocus*.

2. The cosmetic is the result of an elaborate treatment of safflower, etc.

Rough-cast. (*Plastering.*) A mode of finishing outside work by dashing over the second coat of plastering while quite wet a layer of washed fine gravel mingled with lime and water.

Rough-coat. (*Plastering.*) The first coat on lath. On brick it is termed *laying* or *pricking up*; on masonry, *rendering* or *roughing*.

Rough-file. A file with heavy, deep cuts. The angle of the chisel in cutting is about 12° from the perpendicular.

The grades are as follows, beginning with the coarsest quality:

Rough.	Second cut.
Middle cut.	Smooth.
Bastard.	Dead smooth.

The number of teeth to the inch of a *rough file* are according to the length of the file in inches.

Inches	4	6	8	12	16	20
Cuts	56	52	44	40	28	21

They are commonly termed *ruffs*, in the trade.

Rough′ing. (*Hat-making.*) The *hardening* of a felted hat-body by pressure, motion, heat, and moisture. See HARDENING.

Rough′ing-down Rolls. See ROUGHING-ROLLS.

Rough′ing-in. (*Plastering.*) The first coat of three-coat plastering when executed on brick. See PLASTERING.

Rough′ing-mill. A lapidary's wheel, used in roughing down the surfaces of gems to make facets. It is of iron, mounted on a vertical axis, and its upper disk is touched with diamond-dust for the harder gems. It is followed by the *grinding* and *polishing* mills.

A grinding-mill used by lapidaries, consisting of a small copper disk, with a face turned true and flat and furnished with spicules of diamond imbedded by hammering into the copper.

A similar disk with fine diamond-dust is used for polishing. See LAPIDARY'S MILL.

Rough'ing-rolls. (*Metal-working.*) The first set of rolls in a rolling-mill, which operate upon the bloom from the tilt or shingling hammer or the squeezer, as the case may be, and reduce it to the bar form. It is then cut up by the *shears*, made into *piles* or *fagots*, reheated in a reverberatory furnace, and passed between the *finishing* rolls.

The roughing-rolls revolve at about 70 revolutions per minute, the finishing one of medium size at 140, and small ones at 220 or over. See ROLLING-MILL.

Rough-string. (*Carpentry.*) One of the slanting pieces supporting the steps of a wooden stairs. A *carriage-piece*. The upper end rests against an *apron-piece* or *pitching-piece*.

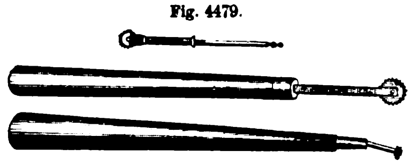
Rough-tree. (*Nautical.*) *a.* A rough or unfinished spar or mast.

b. The portion of a mast above the deck.

Rough-tree Rail. (*Shipbuilding.*) A timber forming the top of the bulwark. It rests upon the *top-timbers*, and caps the external and internal planking.

Rou-lette'. An instrument used in engraving, mechanical drawing, and plotting, for making dotted lines. It has a wheel with points, which, for use on paper, is dipped into india-ink, so that the points

Fig. 4479.



Roulettes.

impress a series of black dots or marks as the instrument passes over the paper. Different patterns of dots are used for national, state, county, and township lines, canals, roads, railways, etc.

Those illustrated are engravers' roulettes, principally used in mezzotinting to raise the burr when the original *ground* produced by the cradle has been too much scraped or burnished away.

Rounce. (*Printing.*) A winch with roller and strap by which the carriage or bed of a press is run in and out under the platen. See PRINTING-PRESS.

Round. 1. (*Joinery.*) *a.* The *rung* or *rime* of a ladder which forms a step, uniting the side pieces. *Round* is the preferable term. It is made out of rived timber, — not sawn, for fear of cross grain, — and dressed by the drawing-knife and spokeshave so as to bulge in the middle, the point of greatest strain. Wedges, driven into their outer ends, secure them to the side pieces. If the *round* does not go through the side pieces the ends are secured by *fox-tail* wedging.

b. The round rail joining the legs of a chair; also known as a *stretcher*.

2. (*Brewing.*) A vessel in which the fermentation of beer is concluded. The *rounds* receive the beer from the fermenting tun, and discharge the yeast at their bungholes into a discharging-trough.

3. (*Ordnance.*) A projectile with its cartridge, prepared for service.

Round Bud'dle. (*Metallurgy.*) A circular frame for working on metalliferous slimes.

Round Chis'el. An engraver's tool having a rounded belly.

Round-edge File. A file with a convex edge; for filing out or dressing the interdental spaces of gear-wheels.

Roun'del. (*Ordnance.*) A disk of iron having a central aperture, through which an assembling-bolt passes. It serves to separate the stock and cheeks. *Rondelle.*

Roun'der. 1. A rock-boring tool having a cylindrical form and indented face.

2. A plane used by wheelwrights for rounding off tenons.

Round File. A file circular in its cross-section.

Small, taper files of this description are known as *rat-tail* files.

Small, round files, without taper, are known as *joint* files, being used for filing out apertures for joint wires and pintles of hinges.

These files are used for *gulleting* saws.

Round-house. 1. (*Shipbuilding.*) A small deck above the level of the quarter-deck or spar-deck, as the case may be, at the after end of the vessel. A *poop*. Sometimes termed the *coach*.

2. (*Railway.*) A circular house with stalls for locomotives around a turn-table.

Round'ing. 1. (*Bookbinding.*) The process of giving a convex shape to the back of a book, hollowing the front edge at the same time.

After the sheets have been folded and sewed together, a strip of paper or thin canvas is glued to the back, and, the book being placed on one of its sides, the back is drawn a little to one side, gently tapping it at the same time with a broad-faced hammer. It is then turned over on the other side and similarly treated, imparting a convex form to the back, which is completed by placing the book in a press between two boards, with the back projecting, and hammering it on each side until the exact degree of curvature desired is obtained. This operation also produces a depression along each edge of the back, into which the side covers of the book lie, so as to present an even surface when attached. This part of the work is also effected by machinery, the book being placed between rollers, which compress it and at the same time draw it up against a former of such a shape as to give the proper convexity to the back.

2. (*Nautical.*) A wrapping on a rope. See SERVING.

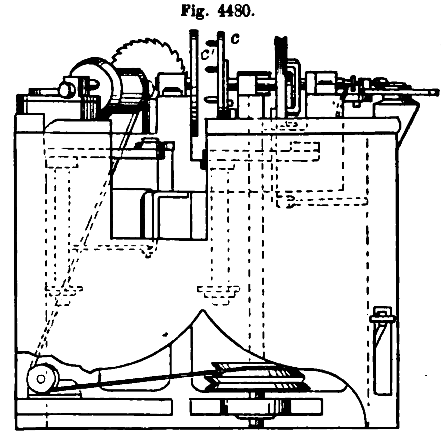
Round'ing-adze. A kind of adze with a curved blade.

Round'ing-gage. (*Hat-making.*) A tool (*d*, Fig. 4481) for cutting hat-brims. The curved portion is kept against the side of the hat, and, as the projecting arm is swept around, a knife held in one of the notches cuts the edge of the brim to an equal width all round. A number of notches are provided, so that the brim may be made of a width to suit the taste or the caprice of fashion.

Round'ing-jack. A stand on which a hat is fixed to have its brim trimmed to shape and size.

Round'ing-ma-chine'. (*Coopering.*) One for giving circular form to the heads of casks. The pieces to form the head are clamped between the

Fig. 4480.

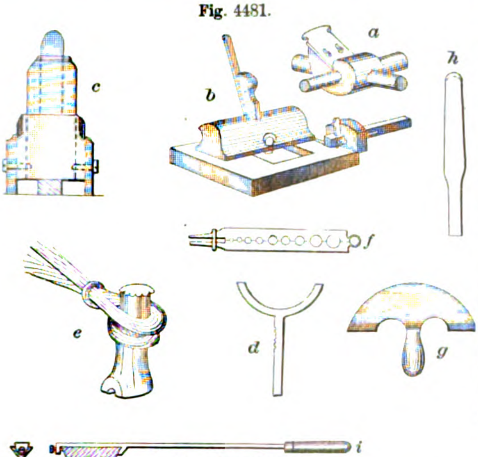


Rounding-Machine for Barrel-Heads.

disks *c c'*, and the protruding portion is trimmed off by the circular saw.

Round'ing-plane. A tool which is a connecting link between the tools of the carpenter and those of the turner. It has a plane-bit which is presented tangentially to the circumference of the circular hole, so that the wood enters in a rough octagonal form and leaves it rounded, being rotated as it passes therethrough. By this, or similar means, the handles of umbrellas, hoes, rakes, pitchforks, and brooms are made; as well as round office-rulers, chair and

Fig. 4481.



Rounding-Tools.

a, Rounding-Plane. b, Router-Plane. c, Reglet-Plane.

ladder rounds, and many articles of similar shape. It is substantially the same as the hollow auger (see AUGER), and is sometimes termed a *witchet.*

Round'ing-tool. 1. (*Forging.*) A top or bottom tool (*e*, Fig. 4481) with a semi-cylindrical groove forming a swage for rounding a rod, the stem of a bolt, etc.

2. (*Saddlery.*) A tool (*f*, Fig. 4481) consisting of a pair of jaws with corresponding, semi-cylindrical notches, which form, when closed, a series of circular openings of varying sizes, through which leathern straps are passed to be *rounded.*

Round-joint File. A kind of clockmaker's file.

Round-knife. 1. (*Leather.*) A currier's circular knife. An annular disk with the edge a little turned over. It is used in scraping skins. (Fr. *Lunette.*) See CURRIER'S TOOLS.

2. (*Saddlery.*) The ordinary cutting-tool (*g*, Fig. 4481) of the saddler, sharp on its convex edge.

Round-nose Chis'el. A tool used by marble-workers for sinking the surface of marble and leveling the cavities. It has at the end a bent portion with serrations, and is a kind of file. See RIFFLER.

Round-nose Plane. (*Joinery.*) A coarse-work bench-plane, the sole of which is rounding.

Round-off File. A small, parallel, half-round file, whose convex side is *safe*, and having a pivot at the end opposite the tang.

It is used for rounding or pointing the teeth of wheels made originally with square notches. The pivot enables it to be readily twisted in the fingers, to allow it to sweep round the curve of the tooth under treatment.

Round-plane. (*Joinery.*) A plane with a round sole for making rounded work, such as stair-rails, beads, etc. A *round-sole* plane; a *rounding* plane.

Round-seam. (*Nautical.*) When the edges of canvas are sewed together without lapping.

Round-shot. (*Ordnance.*) Spherical balls of iron or steel, usually cast. They are solid, while *case* and *shell* are hollow. The term is now little used.

Round-splice. (*Nautical.*) When the splicing is so carefully done that the shape of the rope is scarcely altered. A *long-splice.*

Round-tool. (*Wood-turning.*) A round-nose chisel (*h*, Fig. 4481) for making concave moldings.

Round-turn. (*Nautical.*) One turn of a rope around a timber; or of one cable around another, caused by the swinging of the ship when at anchor.

Round-up. (*Shipbuilding.*) The convexity or arch of a deck.

Rouse-a-bout' Block. (*Nautical.*) A *snatch-block* of large size. See SNATCH-BLOCK.

Rous'er. A stirrer in the hop-copper of a brewery.

Rout'er. (*Joinery.*) A sash-plane made like a spokeshave, to work on circular sash. It may be an *ovolo* router or a *lamb's-tongue* router, according to the nature of the molding.

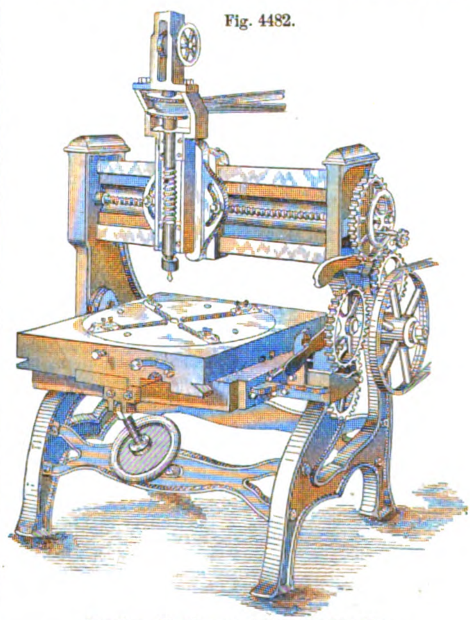
Rout'er-gage. A gage (*i*, Fig. 4481) with a stem and adjustable fence, and provided with a tooth like a narrow chisel, adapted to cut a groove in wood or brass, for the purpose of inlaying.

Rout'er-plane. It has a broad surface, carrying in its center one of the cutters belonging to the plow. It is used for leveling the bottoms of cavities. The stock must be more than twice the width of the recess, and the projection of the iron determines the depth. The sides of the cavity are prepared beforehand by the *chisel* and *mallet*, the *saw*, or the *cutting-gage.* See *b*, Fig. 4481.

Rout'er-saw. A saw having a cutting point on each side of the blade, adapted to cut into the wood, and a less prominent router tooth to remove the chip between the marks or kerfs made by the cutters.

Rout'ing-ma-chine'. A *shaping-machine* which works by means of a router-cutter, adjustable itself,

Fig. 4482.



Routing, Slotting, and Shaping Machine.

and revolving above a bed with universal horizontal adjustment, so as to permit the cutter to follow along a traced line, and thus cut to a shape, or groove to a depth, the work upon the table.

It is adapted for work in metal or stone; in the latter case, black diamonds are used. Paneling in relief or intaglio, raised or sunken lettering, circular slotting, slotting, key-seating, beveling, bordering, may be done upon it.

The cutter-spindle is fixed in a head-block which traverses to the right or left, and may be inclined to any required angle. By means of a hand-wheel and suitable mechanism, the spindle may be raised instantly to clear any obstruction without stopping the machine. The spindle and the feed motions are driven by belting from pulleys not shown in the engraving.

The bed of the machine traverses backward or forward. By means of a screw working in a swiveled nut, the bed may be inclined to any required angle from the horizontal plane. In the center of the bed is a rotating face-plate with automatic feed. By a combination of the backward and forward movements of the bed and the rotating face-plate which carries the piece to be worked, ovals may be cut. The feed-motions are all connected, disconnected, or reversed by simple devices, without interfering with any other motion of the machine. There are four feed-motions: one raises or lowers the spindle, a second traverses the head-block to the right or left, a third traverses the bed-plate backward or forward, a fourth causes the circular face-plate to rotate to the right or left. The inclination of the spindle or the bed does not interfere in the least with the automatic action of these several feed-motions.

Rout'ing-tool. (*Metal-working.*) A revolving tool used for scorping out metal. Such are used in digging out the spaces between and around block-letters and bookbinders' stamps. Also in deepening the "white" spaces in stereotype and zincographic plates, etc. Also for deepening broad spaces in the lettering of door-plates. See ROUTING-MACHINE.

Rove. 1. (*Boat-building.*) A small copper ring or washer, upon which the end of a nail is clinched on the inside of a boat.

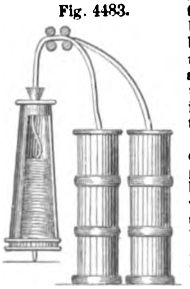
2. (*Spinning.*) A *sliver* of wool or cotton, slightly compacted by twisting, ready for the farther processes, which vary somewhat with the respective materials. See ROVING.

Rov'ing. (*Cotton-manufacture.*) 1. A slightly twisted *sliver* of cotton or other carded fiber.

2. A process intervening between carding and spinning, in which a number of *slivers* from the carding-machine, contained in separate cans, are associated by being conducted between pairs of rollers (see DOUBLING), and then between other successive pairs, by which the combined sliver is reduced and elongated (see DRAWING-FRAME); the sliver, as it issues from the last pair of rollers, being brought to the condition of a *rove*, *roving*, or *slub* by being slightly twisted by mechanical means, which may consist of one of the three following: —

a. Arkwright's plan was to conduct the slivers from the separate cans to a pair of rollers where they were coalesced (*doubling*), then between a pair more rapidly revolving, by which they were attenuated (*drawing*), and from thence the combined and lengthened *sliver* was conducted to a rapidly revolving can, which gave it a twist and brought it to the condition of a *roving* or *slub*.

Fig. 4483.



Roving-Machine.

b. Another plan was the *jack-frame* or *jack-in-a-box*, in which the twist was given by the revolution of the can as before, but instead of being coiled up within the can, the roving was wound upon a bobbin inside the can, the bobbin being rotated by wheel-work with a surface velocity corresponding to that of the delivery drawing-rollers. See JACK-FRAME.

c. A third plan, which is later and preferred to the before-mentioned, belongs to the domain of spinning, its functions being similar and differing only in the degree to which the twist is carried.

The machine is called the BOBBIN AND FLY FRAME (which see). The slivers are wound on bobbins, and the latter are arranged upon a *creel*. The slivers pass from the bobbins through a set of drawing-rollers, and thence to the spindles on which they are wound.

The *sliver* passes through the axial opening of the flyer, and thence down the hollow arm of the flyer, from whose end it is wound upon the bobbin, which has an up-and-down motion by means of the *copping rail*, so as to wind the yarn into a regular form, called a *cop*. See COP.

The *spindle* and flyer revolve together, and give the twist to the *sliver*, but the degree of twist depends upon the ratio of the surface speed of the delivery-roller and the rate of the spindle.

The spindle and the bobbin are revolved by different means and at different rates, in order to wind the thread upon the bobbin; the difference between the motions of the bobbin surface and the delivery arm of the flyer being equal to the surface motion of the delivery-roller, the thread is wound as fast as it is paid out, receiving a twist *in transitu*. See EQUATIONAL BOX.

Bobbin and fly frames are of two kinds, *coarse* and *fine*, or *first* and *second*. The former is fed with *slivers* from *cans*, and the latter with *slivers* wound on *cops* made in the *coarse roving-frame*. See BOBBIN AND FLY FRAME.

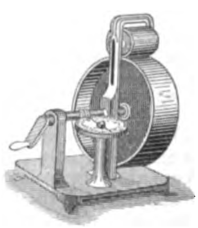
Rov'ing-frame. The roving-frame for worsted is similar to that for cotton. It takes in two slivers from the cans of the *drawing-frame* and elongates them four times, giving them a slight twist to impart coherence. See previous article.

Rov'ing-head. A roving-frame used in the worsted manufacture.

Rov'ing-plate. A piece of iron or steel plate similar to a joiner's scraper, which is held to the top of a grindstone with its edge inclined at a small angle, for the purpose of smoothing its surface.

Rov'ing-reel. A device for measuring the length of a roving, sliver, or hank of yarn. It has a drum and a small presser-roller, between which the roving is drawn by turning a crank on the axis of the drum; the axis has a worm cut on its periphery, which turns a dial-wheel indicating, by means of a pointer, the number of yards which have passed between the rollers; when the crank-handle is down, the dial stands at zero.

Fig. 4484.



Roving-Reel.

Row'el. A spiked wheel, as, —

1. (*Saddlery.*) *a.* The stellar wheel of a spur.

b. The flat ring in a horse's bit.

2. (*Agricultural.*) The spiked wheel of the Norwegian harrow and other soil pulverizers. See HARROW.

Row'el-ing-nee'dle. (*Farriery.*) An instrument used in farriery to insert a rowel through the skin of a horse. A rowel consists of hair or silk, or is even a roll of leather, and corresponds to a *seton* in surgery.

It is sometimes inserted in a gash, in the manner of a *tent*.

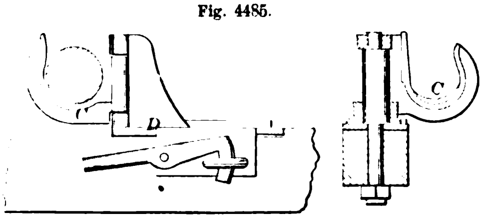
Row'el-ing-scis'sors. An instrument used in inserting *rowels* in the flesh of horses.

Rowl. (*Nautical.*) The sheave of a whip-tackle.

Rowle. (*Nautical.*) A light crane, formerly used in discharging cargo.

Row'lock. (*Nautical.*) A crotch or notch on

Fig. 4485.



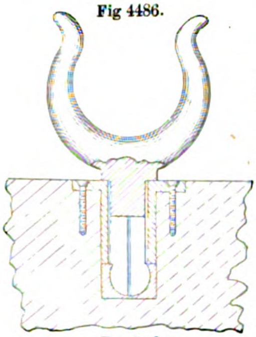
Norcross's Oar-Lock.

the gunwale of a boat, against which the oar works in rowing.

Various devices are used: —

1. Two short pegs or posts rising from the gunwale.

Fig 4486.



Rowlock.

2. An iron stirrup pivoted in the gunwale.

3. An iron pin in the gunwale, and the oar fastened to it by a thong.

4. A pin in the gunwale passing through a hole in the oar.

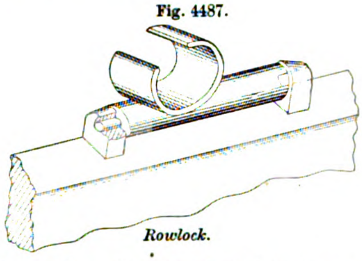
5. A notch in the gunwale.

Fig. 4485 is a hook *C* swiveled on a post *D* which is fastened to the gunwale by a flanged plate, staple, and latch, so as to be unshipped when required.

Fig. 4486 is a fork swiveled in a socket inserted into the gunwale.

In Fig. 4487, the pin of the rowlock enters and

Fig. 4487.



Rowlock.

works in a roller, which is pivoted to two ears attached to the gunwale. See also OAR-LOCK.

Row dry. An order given to the oarsmen to row in such a manner as not to splash the water.

Rowed of all. An order to cease pulling and lay in the oars.

Row-port. (*Nautical.*) Small ports near the water's edge for the *sweeps* or large oars, whereby a vessel is rowed during a calm.

Roy'al. 1. (*Nautical.*) A mast and sail next above the *top-gallant*.

2. (*Paper.*) A size of drawing and writing paper, measuring $23\frac{1}{2} \times 19$ inches and weighing according to quality.

3. (*Ordnance.*) A small mortar.

Rub'ber. A polisher.

1. A grinding agent, as emery or glass paper.

2. *a.* Caoutchouc. See INDIA-RUBBER; CAOUTCHOUC.

b. A block of caoutchouc for erasing pencil-marks.

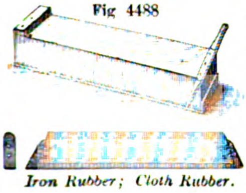
3. A coarse file.

4. A whetstone.

5. (*Fabric.*) *a.* A coarse, unbleached flax toweling for rubbing the body after bathing.

b. A coarse towel used for drying horses.

Fig 4488.



Iron Rubber; Cloth Rubber.

6. (*Masonry.*) A board or block used in grinding or polishing. In the moldings of stone, an iron *rubber* mounted on a wooden stock is employed for fillets, beads, and astragals. These rubbers have convex or concave faces, according to the required contour of the work. A stone or wooden block covered with thick felt is used for polishing stone and marble.

7. (*Electricity.*) *a.* That part of an electrical machine which rubs against the cylinder or disk.

b. The moving pad or piston of an electrophorus.

8. (*Nautical.*) A tool for flattening down the seams in sail-making.

9. A roll of cloth charged with emery, rottenstone, or other abradant or polishing material, for surfacing plates.

10. (*Vehicle.*) The part of the wagon-lock which presses against the wheels.

Rub'ber Cem'ent. 1. Caoutchouc cleaned, triturated with a small quantity (say 3 per cent) of sulphur, and then dissolved in benzine or other hydrocarbon.

In this condition it is ready for spreading on cloth to be cut into shapes to form various articles, such as boots, shoes, coats, buckets, belting, and many other things.

2. For fastening rubber plates or rings to metal or wood. A solution of shellac in ten times its weight of strong ammonia. Left to soften for weeks without heat.

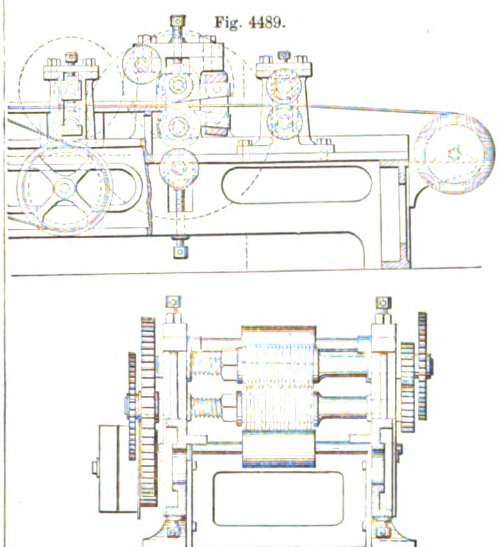
Rub'ber-cloth. 1. Fabric covered with caoutchouc.

2. Caoutchouc in sheets. See CAOUTCHOUC; INDIA-RUBBER.

Rub'ber-cut'ting Ma-chine'. A machine for making threads of caoutchouc for *shirrs*.

Jacques' machine is shown in Fig. 4489 by longitudinal and transverse vertical sections. It has a

Fig. 4489.



Jacques' Rubber-Cutting Machine.

series of disks with square cutting-edges and mounted upon spindles, arranged in such proximity to each other as to allow the disks of one spindle to mesh with the disks of the other. The disks on each spindle are prevented from revolving thereon by means of a spline or feather, and are separated by gage-plates of a thickness equal to the thickness of the cutters, and of a diameter sufficient to support the sides of the disks during the cutting operation, so that they shall not deviate laterally.

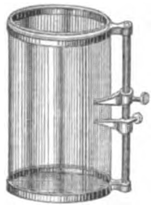
Rub'ber-file. A heavy, fish-bellied file, designated by weight, which varies from four to fifteen

pounds. They are of square or triangular section, and used for coarse work.

When they have three flat faces and one rounded, they are known as *half-thick* files.

Rub'ber-gage. A device for ascertaining the quantity of india-rubber required to make a given article. The vessel (Fig. 4490) is partially filled with water, and the lower index set at the hight of its level. The model of the object is then immersed in the water and the upper index set at the point to which the water rises. The model being removed, the vessel is again filled to the hight of the lower index; rubber is added until it rises to the upper index. The amount required to make it do this is that which the article requires for its manufacture, to which an addition may be made for loss or wastage.

Fig. 4490.



Rubber-Gage.

Rub'ber-knife. A circular blade rotated at high speed and kept constantly wet by a jet or spray of water. It is technically known as a *rubber-saw.*

Rub'ber-mold. 1. A flask or former for shaping plastic rubber.

2. A vulcanite mold for shaping plates for artificial dentures, etc.

Rub'ber-mount'ing. (*Saddlery.*) Harness mounting in which the metal is covered with vulcanized india-rubber in imitation of leather-covered work.

Rub'ber-saw. A tool used in cutting india-rubber, — caoutchouc. It is not properly a saw, but is so termed in the trade. It is a circular knife, driven at high speed, and kept constantly wet by a jet or spray of water.

Rub'bing. The process of straightening the wires for needles. The wire is furnished in coils, from which the blanks are cut in double lengths. The bend is taken out of them by a process called *rubbing.* Several thousands of the pieces of wire are collected within two broad and heavy rings placed on a shelf in the furnace, and heated to redness. A slotted bar, called a smooth file, is then pressed upon the needles in the pack, the rings projecting into slots in the bar, which is reciprocated endways, so as to rub the wires against each other as the pack rolls back and forth until, by mutual attrition, the bend is all taken out.

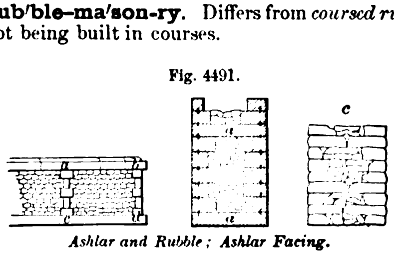
Rub'bing-paunch. (*Nautical.*) A piece of wood nailed on the foreside of a mast to prevent injury to the latter by yards or spars in raising or lowering.

Rub'bing-stone. (*Bricklaying.*) A grit-stone, which is placed upon the *banker* or bricklayer's bench, and upon which stones are rubbed smooth after being dressed by an axe to a shape suitable for gaged arches, domes, niches, or similar work.

Rub'ble. (*Masonry.*) Broken stone, brickbats, small stones used in filling behind the face courses of walls.

Rub'ble-ma'son-ry. Differs from *coursed rubble* in not being built in courses.

Fig. 4491.



Ashlar and Rubble; Ashlar Facing.

Coursed and *rubble* masonry are sometimes combined, and produce a rusticated effect, as in the illustration, where the coping *a b*, the piers *a c*, the plinth *c d*, and the quoins *b d* are of *coursed* masonry, giving solidity to the wall and adding to its appearance. With thick walls, the facing may be of *ashlar*, filled in with rubble. Occasional *bond* or *heading* stones *a* keep the facings from settling apart.

Rub'ble-work. (*Masonry.*) Masonry in which stones are used in the rough without being dressed to size, unless on their exposed faces (*c*, Fig. 4491).

It is *regular coursed* when the courses are of the same hight; *irregular coursed* when the courses are of different hights; *random* or *uncoursed* when stones of different hights are used in the same course.

Ru-belle'. 1. (*Enameling.*) Probably from the red tourmaline. (Ger. *Rubellan.*) A red color in enameling.

2. (*Metallurgy.*) (Ger. *Rubelle*, from *reiben*, to rub.) An iron plate on which ores are ground to test them or prepare for test by assay.

Rub-ir'on. A plate on a carriage or wagon-bed against which the fore-wheel rubs when turning short.

Called *wheel-guard plate* in a field-artillery carriage; one is placed on each side of the stock.

Rub-stone. The flat stone on which the currier's knife is ground to an edge. The *clearing-stone* is one of finer grain, on which the knife receives a more perfect edge, which is then turned over by a *steel.*

Ru'by. 1. (*Printing.*) The name given in England to a type corresponding to that called *Agate* in the United States. See AGATE.

Pearl.
Agate or Ruby.
Nonpareil.

2. (*Horology.*) The jewel of a watch. The *end-stone* is usually a ruby in first-class work.

Rud'der. 1. (*Nautical.*) A flat frame hung to the stern-post of a vessel and affording a means of steering.

The *pintles* of the rudder are hooked upon the *eye-bolts* of the stern-post, which afford an axis of oscillation as the rudder is moved to and fro by the tiller.

Rudders are not as old as boats by any means. The first rudder was a paddle or oar held over the stern. One is shown in the sculptures of Nimroud.

The Nile boats of ancient Egypt had rudders, one, two, or three in number; sometimes the oar traversed on a beam at the stern, or it was slung from a post on which it was pivoted.

The rudder is shown in two forms in the ancient paintings of Edfou; projecting at the stern like an oar, and pivoted vertically. The latter form has the *tiller.*

Hesiod recommends to hang up the rudder in the smoke of the chimney when out of service.

The rudders of the ancients were paddles which protruded through ports in the stern, or rested in rowlocks on the taffrail of the ship or boat. In the tempestuous voyage of Paul, when they had "discovered a certain creek with a shore, into which they were minded, if it were possible, to thrust the ship," they took "up the anchors," "committed themselves unto the sea," loosened the fastenings of the rudders, "hoisted the mainsail to the wind, and made towards shore." Paul wrote well on every subject he undertook, and the account of his voyage gives us a better idea of the mode of navigation 2,000 years ago than any other work which has come down to our time. The rudders, where more than one was used, were on each quarter, protruding through holes in the counter.

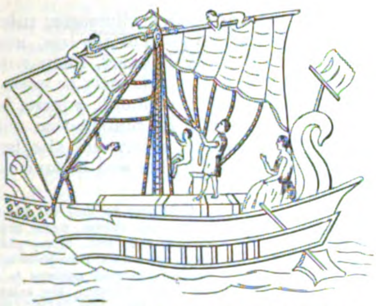
The foremost part of the frame of a rudder is the *rudder-stock.* Its slope is termed the *rake* of the rudder; this depends on the rake of the stern-post. Its upper cylindrical end is the *rudder-head.* It rises through the *rudder-port* in the stern. Its lower end is the *heel*, and rests on the *step.* It turns on *pintles*, fitting into eyes called *braces*, on the *stern-post* or *rudder-post.*

The front edge of the rudder is *bearded* or beveled, to allow it to be *put over* either way to a greater angle.

Rudders are *sheathed* with copper or mixed-metal sheets.

The rudder, when hung, is guarded against being *unshipped* by a movable piece called a *wood-lock*, which is screwed upon

Fig. 4492.



Ancient Ship (from a Painting at Pompeii).

the stern-post or rudder, and fits into a score a little above the uppermost pintle.

Lumley's two-leaved rudder (English) has a *body* hinged to the stern-post in the usual way, and a *tail* hinged to the body. The parts are also connected by a *yoke*, which causes the tail to assume the same angle relatively to the body that the body does relatively to the ship.

Rudder-chains and *pendants* are chains securing the rudder to the stern. See RUDDER-CHAIN.

The *rudder* is moved by the *helm*. This may be a mere lever, called a *tiller*, moving in a horizontal plane. Such was the original device, still used in boats and by Chinese navigators.

Another form is the *yoke;* a horizontal bar on the rudder-head, athwartship, and having ropes from its respective ends, which are used by the coxswain or steersman in moving the rudder. This is common in boats.

The usual form in ships consists of a wheel (see STEERING-WHEEL) with ropes or chains winding on the axis of the wheel and passing through sheaves to the tiller or yoke on the rudder-head.

On the steamboats of our Western and Southern rivers, a tiller is dispensed with, the rudder being operated by wire cords or chains which proceed from the steering apparatus in the pilot-house or "Texas," on the hurricane deck. The chains are made fast to the outer extremity of the rudder. Hempen cords were formerly used, but several accidents having been made much more fatal from the cords burning off, rendering the vessel unmanageable, wires and chains have been generally substituted.

2. (*Agriculture.*) A sieve for separating the chaff from the grain. Probably a corruption of RIDDLE.

Rud′der-band. (*Nautical.*) That member of a rudder-hinge which has bands to brace the rudder and an eye for the pintle on the part attached to the stern-post.

Rud′der-breech′ing. (*Nautical.*) A rope for lifting the rudder to ease the motion of the pintles in their gudgeons.

Rud′der-case. (*Nautical.*) The well in the stern occupied by the rudder-stock. The *rudder-trunk.*

Rud′der-chain. (*Nautical.*) One of the chains whereby the rudder is fastened to the stern quarters.

They are shackled to the rudder by bolts just above the water-line, and hang slack enough to permit the free motion of the rudder. Their use is to prevent the rudder being lost in the event of its becoming unshipped. They also sometimes led in-board, to be used in steering should the rudder-head or tiller give way.

Rud′der-coat. (*Nautical.*) A canvas clothing to the rudder-stock, which keeps the sea from passing through the trunk in the counter.

Rud′der-pen′dant. (*Nautical.*) A continuation of the rudder-chain, secured by a staple around the quarter, under the molding. In the end of the pendant a thimble is spliced, to which may be hooked a tackle, in case the tiller or head of the rudder is carried away.

Rud′der-port. (*Shipbuilding.*) The hole in a ship's counter for the passage of the rudder-head.

Rud′der-tack′le. A tackle employed for operating the rudder in case its head is carried away or for working a make-shift rudder.

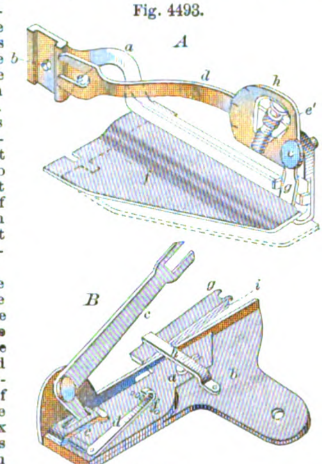
Ru-den′ture. (*Architecture.*) The figure of a rope or staff, sometimes plain, sometimes carved, with which the third part of the flutings of columns is frequently filled up.

Ru′der-a′tion. A term used by Vitruvius for laying of pavement with pebbles.

Ruf′fle. A strip gathered and sewn on one edge and the full edge hemmed. A *double ruffle* is full on both edges and gathered in the middle. A *puff* is gathered on both edges and full in the middle.

Ruf′fler. 1. A sewing-machine attachment for forming ruffles in goods. That illustrated at *A*, Fig. 4493, is Toof's, particularly designed for the Singer machine, but its mode of attachment may be varied to suit other machines.

Fig. 4493.



Rufflers.

The arm *a* is connected by a screw at *b* to the presser-foot bar of the sewing-machine, and to it is connected by a rivet *c* the lever *d*, which is forked at *e* to receive the nut securing the needle, from which nut it derives motion.

The lever *d* carries a set-screw *e′* for adjusting the amount of movement given to the feed-plate *f* at each reciprocation of the needle, which passes through a slot at the rear of the feed-plate.

The goods are placed between the feed-plate and the presser-foot of the machine, and as the needle passes upward and downward, carrying the long arm of the lever *d* with it, the arm *g* of the index device *h* reciprocates the feed-plate to an amount previously regulated by the adjustment of the screw *e′*; at each forward movement the feed-plate acts on the presser-arm, carrying forward and folding the cloth, which is penetrated by the needle as the latter descends and causes the backward movement of the feed-plate.

In the Johnston ruffler (*B*, Fig. 4493), a sliding-plate *a* is secured to the bed-plate *b* of the machine by rivets or screws passing through slots in the plate, so as to permit the necessary motion. The plate *a* is reciprocated by the forked lever *c* operated from the needle-bar. The movement of the plate *a* and the depth of the gather or ruffling are regulated by a bent lever *d* pivoted on the sliding-plate. One arm of this lever passes under a slotted piece *e* attached to the sliding-plate, and the other has a projection at its end for holding it in either of a series of notches *f*. The cloth is held between a spring *g* attached to an arm *h* on the bed-plate, and a spring *i* connected by an arm to the sliding-plate, which is reciprocated at each movement of the needle to a distance determined by the previous adjustment of the lever *d*.

2. A sort of heckle for flax.

Ruff-wheel. (*Metallurgy.*) An ore-crushing mill for the pieces which will not feed into the usual crusher.

Rug. (*Fabric.*) A nappy fabric made for a wrapper, cover, or protection.

A *railway-rug* is a coarse shawl for wrapping the legs or for use as a blanket.

A *bed-rug* is a nappy, woolen, colored blanket.

A *hearth-rug* is a tufted fabric on a backing consisting of a hempen, linen, or cotton web. It is made in the manner of a Turkey carpet. The vertical chain of the web is stretched between the *yarn-beam* above and the *cloth-beam* below. A number of

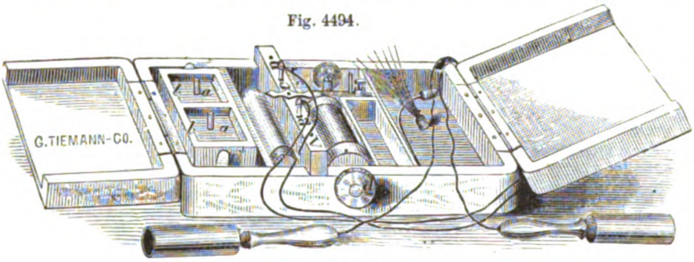
colored worsted yarns are hung over a bar to the right of the weaver, who, taking the end of one yarn, attaches it to the chain, cuts it off to the proper length, then twists in another, which he severs in the same manner, and in this way forms a row of tufts across the warp. He next passes a shoot or two of weft, and drives the weft against the web with considerable force to compact the fabric.

Rug'ging. 1. (*Fabric.*) Coarse woolen wrapping or blanket cloth.

2. (*Saddlery.*) A coarse cloth used for the body of knee and other horse boots.

Ruhm'korff Bat'ter-y. Fig. 4494 shows Tiemann's Ruhmkorff battery for medical purposes. *b b* are the cells, and *a a* elements of the piles. In the middle compartment is shown the induction-coil, and on the partition are holes *A B C D* forming a kind of peg-switch. The two connectors are placed in one or other of the holes, according to the required extent of the length of coil desired to be embraced in the circuit.

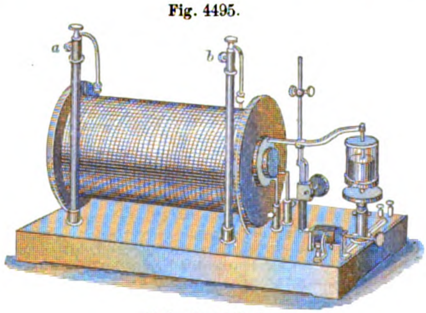
Fig. 4494.



Tiemann's Ruhmkorff Battery.

Ruhm'korff Coil. A form of coil devised by Ruhmkorff, for causing intense electro-magnetic cur-

Fig. 4495.



Ruhmkorff Coil.

rents by induction. It consists of an inner primary coil, made of wires about No. 15, wire gage, in diameter, forming part of the circuit of a battery, and having an axial bundle of straight wires of soft iron, united at each end to a disk of similar metal. The outer, secondary coil is of much smaller wire, about No. 32, wire gage, in diameter, and very much greater length. In a large apparatus, the former might be about 90 yards, and the latter 90 miles long. The convolutions of the secondary coil are carefully insulated from each other and from the primary coil, and its ends are secured by binding-screws *a b* supported by glass pillars. See INDUCTION-COIL; INDUCTORIUM.

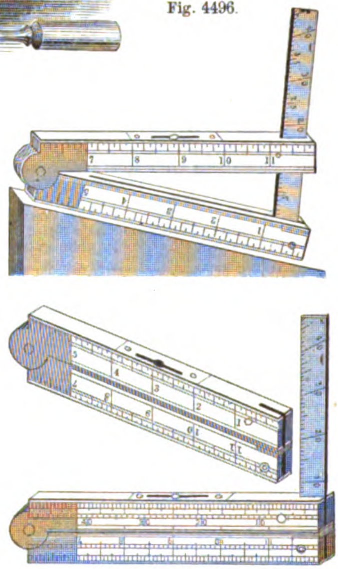
Ru-ille'. (Fr. *ruillée.*) (*Building.*) A pointing of mortar at the junction of a roof with a wall higher than itself. A fillet of mortar to shed the water.

Rule. An instrument for making linear measurements. It is divided into inches and fractions, and is usually jointed, so that it may be folded up and carried in the pocket. Those used by some classes of artificers are, however, made in a single piece.

Fig. 4496 is denominated a clinometer rule. A small spirit-level is set into one of the legs, and being provided with a pivoted branch folding into a cavity in the other leg, the rule may be used as a clinometer or slope level; a plumb, square, bevel, protractor, or T square; in combination with a straight edge, as a parallel ruler, and also for approximately determining hights and distances trigonometrically.

"Abroad to find out one to engrave my tables upon my new sliding rule with silver plates, it being so small, that Browne, that made it, cannot get one to do it. So I got Cocker [the celebrated arithmetician, Ob. 1679], the famous writing master, to do it, and I set an hour by him, to see him design it all." — PEPYS'S *Diary*, 1664.

Fig. 4496.



Rules.

Some rules have a slider in one leg; in Gunter's scale this is graduated and engraved with figures, enabling various simple computations to be made mechanically.

When Dalton (who died in 1844, æt. 78) made known his discovery of the theory of chemical equivalents, Dr. Wollaston invented a sliding rule, on the principle of Gunter's, for facilitating chemical calculations; it was employed for determining the chemical equivalence of compound bodies, and the proportion of one substance necessary to decompose another.

Pattern-makers use a rule whose divisions are made a certain per cent longer than standard measure. Iron castings shrink in cooling about 1 per cent, or $\frac{1}{8}$ of an inch to a foot. The patterns therefore require to be made proportionately larger. By using a rule $\frac{1}{8}$ inch in a foot longer than the standard, every measurement of the pattern is made proportionately larger without the trouble of calculation.

When a woolen pattern is made, from which an iron pattern is to be cast, the latter being intended to serve as the permanent, foundry pattern, as there are two shrinkages to allow for, a *double-contraction rule* is employed, or one in which the measurements are in excess ¼ inch in every foot, for iron.

The shrinkage of brass is about $\frac{3}{16}$ of an inch to the foot. Iron castings weigh about 14 times as much as the pine patterns.

2. (*Printing.*) *a.* A thin plate of metal, used for separating headings, titles, the columns of type in a book, or columns of figures in tabular work.

Rules are of the same hight as the type, and some have a guttered face so as to print a double line.

b. A slip of metal laid above the last line set, to facilitate placing type in the stick.

3. (*Plastering.*) A strip or screed of wood or plaster, placed on the face of a wall as a guide to assist in keeping the plane surface.

Rule-joint. A movable joint in which a tongue on one piece enters a slot in the other, and is secured by a pin or rivet. When the two pieces are in line, their ends abut, so that movement is only possible in one direction. This arrangement is used for carpenter's rules and table-leaves.

Rul'er. An instrument with straight sides, for guiding a pen, pencil, or scriber in drawing straight lines. The fiducial edge, when divided, enables linear measurements to be laid down therefrom.

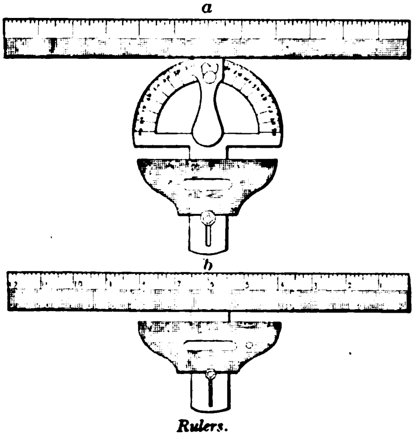
The *regula* (ruler) of the ancient Romans was thus divided, as are the rules of carpenters and other artisans at present.

Desk-rulers are either flat or round; the first have a beveled edge to prevent ink flowing from the sides of the pen on to the paper. The round form is very convenient for ruling parallel lines by one accustomed to its use.

The common parallel ruler is composed of two straight-edged arms, which are kept parallel by means of two pieces pivoted to each. Sometimes an intermediate parallel piece is interposed, or a single straight-edge, having a roller near each end, is employed.

The universal adjustable ruler (*a*, Fig. 4497) comprises a graduated straight-edge and a protractor, enabling angular

Fig. 4497.



Rulers.

measurements to be made or parallel lines to be drawn at any angle with the edge of the table or drawing-board.

The ruler *b* is also adapted for drawing parallel equidistant lines; the protractor being dispensed with.

There are several varieties used for drawing parallel lines.

a. Two-part ruler; the most usual kind.

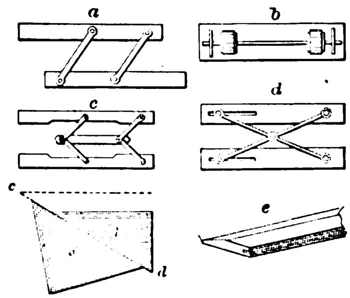
b. Dollond's ruler; has a roller near each end.

c. Three-part ruler.

d. Cross-brace ruler.

The draftsman's table is provided with two triangles; one having the angles of 45° and 90°, and the other, 30°, 60°, and

Fig. 4498.



Parallel Rulers.

90°. By holding the former of these steady with the left hand, at such an adjustment that the edge of the triangle shall be coincident with the given line, a line parallel with the said line may be obtained either above or below it, by slipping the triangle *b* on the triangle *a*.

e has a metallic straight-edge imbedded in the face.

Other rulers have parallel hinged slats, or consist of an elastic straight-edge, which will yield to the bent pages of a record or account-book; a straight-edge considerably elevated from the paper to prevent ink soiling the latter; one provided with clamps to secure it to the edges of a book; containing recess for holding pencil or pen, made of folded sheet metal or both; T-shaped for ruling lines parallel or at right angles to edge of book.

Rule-staff. (*Shipbuilding.*) A lathe about 4 inches in breadth, used for laying off curves.

Rul'ing-ma-chine'. An arrangement for ruling sheets of paper for blanks or for writing.

The simplest ruling-machine, perhaps, is a pen and straight-edge. A cylindrical ruler with a guide for the ruling-pen is a common device.

In ruling paper with *faint* lines for writing, the sheets are passed singly under a series of ruling-pens, arranged at proper distances apart to give the lines.

The pen is a bent strip of thin sheet-metal, forming a trough, down which the ink or dye runs from a bit of cloth or sponge, which is saturated with the fluid. Two or more colors may be ruled in parallel lines by employing a set of pens for each color.

Blank-books and blanks with printed headings are preferably ruled of late years by the ruling-machine, instead of on the letter-press, the rules in the latter case making an impression in the paper which is liable to catch the pen.

Perpendicular rules are sometimes drawn from different points at the top of the page, when heads and sub-heads are printed on the paper. This is accomplished in a ruling-machine by raising some of the pens until the sheet has passed to the point from which the lines are drawn, when the pens are lowered to the paper. This is accomplished by hand, or by a cam movement operating a *striker*.

All the pens are lifted at once at the foot of the sheet, generally by a cam mechanism.

Blanks and blank-books are generally printed before ruling.

The ruling of note and letter paper on three pages is accomplished by a cam movement which raises the pens when halfway across the outside of the sheet. The expense of ruling on three pages is therefore greater than where the paper is ruled entirely across.

Compound lines, as the heavy lines in account-books, when of two colors, are ruled by pens of different length, one pen extending forward on the machine beyond its neighbors. The lines are thus brought close together without crowding the pens, and the dye first run upon the paper has an instant of time to *set* before the second color is reached.

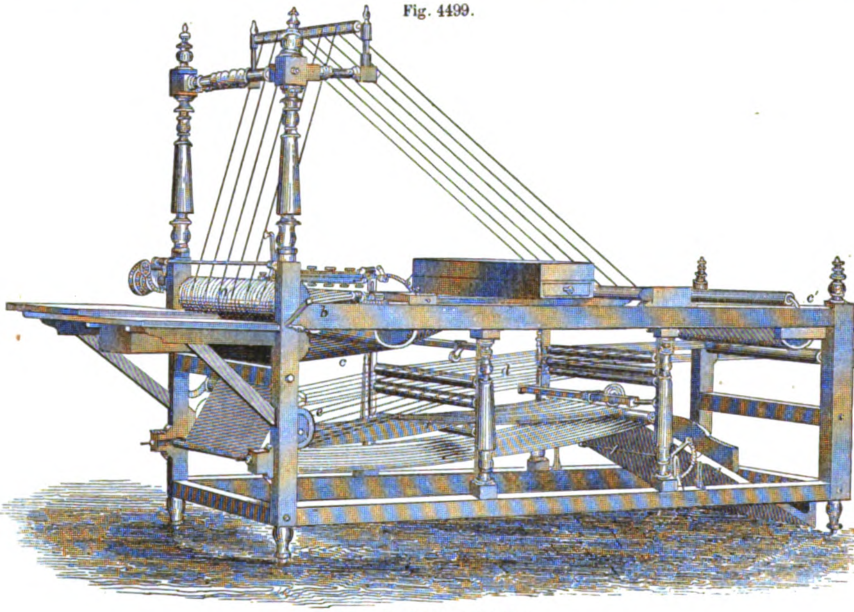
Zigzag, wavy, and cross lines are ruled on bank-notes, checks, etc., by giving the paper a double motion while under the pens. Very neat designs and tints are sometimes secured in this way.

In Hickock's machine, the sheets from the feed-table are received by the roller *a* and carried, by an endless belt and cords, beneath the row of pens *b*, from which they are conveyed by the cords *c* to the other end of the machine, and after passing

around the roller c', travel upon the cords d to e, where they are transferred to the cords f, by which they are conducted to the delivery-board g, having thrice traversed the whole length of the machine. This is done in order to dry the ink.

The pen-holder for ruling-machines (Fig. 4500) consists of an arm a secured to the ruler-bar in such a way that the distance between the holders composing the set may be varied. The other end has a pair of jaws, between which a double pen b is secured

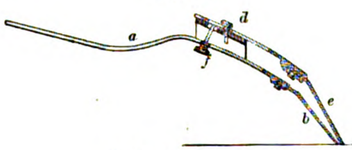
Fig. 4499.



Hickock's Ruling-Machine.

by a set-screw. Above, and hinged to the arm a, is a second sliding-holder c, which may be held fast by the set-screw d. This

Fig. 4500.



Ruling-Machine Pen.

receives a single pen e. The distance between the pens b e is varied by means of a set-screw f.

2. (*Engraving.*) The invention of Wilson Lowry. This consists of a carriage traveling in a groove or on a bar, and carrying a diamond-pointed stylus, which makes a line through the *ground* covering the plate. The line being drawn, a thumb-piece lifts the stylus, and the carriage is retracted. Then, by a lever arrangement, the carriage track is shifted laterally the distance between two lines. This distance is regulated according to requirements for wide or narrow ruling, and when set, the distance is preserved until the job is finished, unless by a gradual increase or decrease in the sweep of the *distance-lever*, the ruling is gradually made more or less open. In line engraving, the sky and still water are usually ruled in by the machine. In the commoner class of line engravings it is also much used for throwing an even tint, either light or dark, over an object. It is considered by the profession to be unworthy of the artist, as cheapening the process and degrading the purity of the art. The effect of ruling in these latter cases gives a smooth mezzotint effect, is easily accomplished, and is pleasing to those who do not care for the conventionalities of the art.

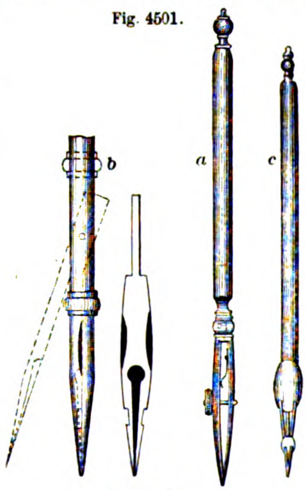
Rul′ing-pen. (*Drawing.*) A pen used for drawing lines of equable thickness. For this purpose, the nibs or the ink-channels, as the case may be, are adjusted for a given width of line, irrespective of pressure; in this respect differing from the writing-pen, which gives a line of varying thickness, according to pressure.

Ruling-pens are for hand or machine. The ordinary ruling-pen a has a pair of steel blades attached to the end of a holder and having even, sharp, elliptical ends, which may be regulated as to relative distance, according to the width of the line required. The pellicle of ink is contained between the blades. A second form of ruling-pen b was introduced from France perhaps forty years since. The instrument has a pair of jaws which shut perfectly together, inclosing an ink reservoir. At the tip of the pen is a small aperture, out of which the ink flows.

Christie's ruling-pen c has a triangular arrangement of converging points, which hold a drop of ink; the small triangular hole between the needle-points forms the ink-duct.

Such pens are commonly made of glass of late years, and are hawked about the streets.

Fig. 4501.



Ruling-Pens.

The ruling-pen for machines, by which letter and account-book paper are ruled, is made by doubling a piece of thin sheet-brass, forming a small trough for the ink. The end of the trough is cut obliquely, so that it rests on the paper, — the width of the line depending on the width of the pen; the depth of color partly on the composition of the ink, and partly on the

speed of the tool over the paper or of the paper under the tool, the latter being usual in ruling-machines.

The ink is furnished by a wetted strip of flannel, which is laid above the gang of pens. (See RULING-MACHINE.) The *music-pen* is similarly constructed. See MUSIC-PEN.

Rum'ble. 1. A rotating cylinder or box in which articles are placed to be ground, cleaned, or polished by mutual attrition. Grinding or polishing material or merely sawdust or bran may be added, according to the need of the subject. Chains are cleaned of rust, castings of sand and scale. Small articles are polished by means of the rumble.

The machine is extensively used in various trades, sometimes being called a *tumbling-box* or a *shaking-machine*. It is used,—

For polishing needles, pins, and steel-pens with sawdust and bran.
For polishing bone buttons with sand.
For polishing lead-shot with graphite.
For scouring small castings to remove the sand coat.
For brightening tacks in water before tinning.
For cleaning the rust off cannon-balls.
For drying coin blanks, etc., in sawdust.
For dissolving gums in spirits of wine for making lacquers and varnishes.

2. (*Vehicle.*) An elevated seat behind the body of a carriage.

Rum'bow-line. (*Nautical.*) Condemned canvas, rope, etc.

Rum'swiz-zle. An Irish fabric made of undyed foreign wool.

Run. 1. (*Mining.*) The *direction* or *lead* of a vein of ore, or a seam or stratum of other mineral, as of coal or marble.

2. (*Founding.*) A mold is said to *run* if the metal makes its way along the parting, or in any other way appears on the outside edges of the flask. It is avoided by *weighting* the flask.

3. A plank laid down to support rollers in moving buildings and other heavy objects. Also as a track for wheelbarrows.

4. (*Nautical.*) *a.* The aftermost part of a ship's bottom, which becomes gradually narrower from the floor-timbers to the stern-post.

b. The course or distance sailed by a vessel.

c. To *run out a warp, hawser,* or *cable* is to carry out its end to any object, for the purpose of mooring, warping, etc.

To *run out the guns.* To force their muzzles out of the port by means of the side tackles.

To *underrun* a cable or hawser. To pass along it in a boat, the cable being lifted from the bottom at the bow of the boat and passed out over the stern as she proceeds, in order to examine it or for the purpose of weighing the anchor.

To *let run a rope.* To unloose it.

Run'dle. 1. The *step* or *round* of a ladder. A *rung.*

2. (*Nautical.*) The drum of a capstan.

3. One of the bars in a LANTERN-WHEEL (which see).

Rung. 1. The *round* stick forming a step of a ladder.

2. The spoke of a wallower or *lantern*-wheel, or one of the radial handles projecting from the rim of a steering-wheel.

3. (*Shipbuilding.*) A floor or ground timber of a ship's frame. The spaces between the *rungs* are *spirkets.*

4. One of the bars of a windmill sail.

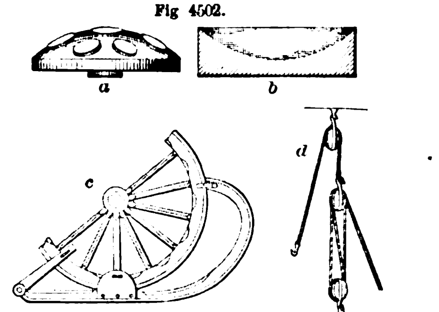
Rung-head. (*Shipwrighting.*) The upper end of a ship's floor-timber.

Run'ner. 1. (*Milling.*) The revolving millstone of a grinding-mill. It is usually the upper stone, but not always. Sometimes both stones (*F*, Plate XXII.) are driven, and thus become the *upper* and *lower* runner, respectively. See GRINDING-MILL.

2. (*Saddlery.*) A loop, usually of metal, used in harness-making to receive a running strap or rein. The gag-rein passes through runners suspended from the throat-latch on each side of the throat.

3. (*Vehicle.*) The curved pieces of a sled or sleigh which *run* or slide upon the ground and support the bed. The best are made from a natural bend or crook, and best of all is to dig up a tree and use the natural bend where the bole of a tree spreads out to form a root. This portion is very tough, and holds the roller well without splitting. (See SLED; SLEIGH.) In factories, where the same amount of care in selection cannot be exercised, runners are made of bent stuff. Farmers prefer a natural crook. The material depends on the part of the country. In Ohio, blue-ash is admired, oak is much used. Red

Fig 4502.



Runners.

beech is lasting, and wears very smooth. *c*, Fig. 4502, shows a runner attached to a wheel to be used, when permitted by the condition of the roads, for sleighing.

4. (*Founding.*) Specifically, the horizontal channel — one or more — cut in the sand from the bottom of the gate to the space left by the removal of the pattern, and through which the metal runs. This term is, however, constantly used as a synonym for *gate* or *git.*

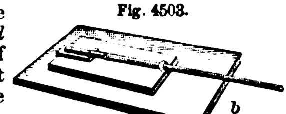
5. (*Nautical.*) A thick rope (*d*, Fig. 4502) rove through a single block, a hook attached to one end and the other passed around one of the tackle-blocks.

It may be applied by attaching the hook of the *runner* and also the hook of the lower tackle-block to the body to be moved; or the lower may constitute a standing block by being hooked to an eye-bolt.

A *whip and runner* has a single block only, attached to the fall of the runner. See TACKLE.

6. (*Optics.*) A convex tool (*a*, Fig. 4503) of cast-iron on which lenses are supported while grinding in the *shell b.* The *shell* is of cast-iron, and is cast upon a *mold* made from a wooden *pattern.* The *pattern* is shaped on the lathe to correspond to a *templet.* The *templet* is a piece of sheet-brass or glass, whose edge is curved to the radius required. This is the backward way of stating it, but is consecutive, starting from the *shell.*

Fig. 4503.



Runner.

7. (*Stone-working.*) The upper, moving slab (Fig. 4503) in the process of grinding and polishing stone. The upper may be a smaller piece of marble or stone, which is ground or polished, as the case may be, while it effects the same upon the lower (*b*). The upper is generally the harder quality.

In some cases, the runner is of iron, with a raised rim around the upper surface to form a tray which holds the sand and water. The bottom of the tray is perforated and allows the abradant to pass through, keeping a constant supply of sand and water to the grinding surfaces.

In each case, sand or other powder is the cutting material.

The *runner* is sometimes termed the *rubber*, for obvious reasons, and is moved by means of a long handle secured to it in the manner indicated.

8. (*Well-boring.*) A loop-shaped piece for taking hold of the *topit* or top-piece of the train of boring-rods.

9. The slider of an umbrella to which the spreaders are pivoted.

Run'ner-ball. (*Gunpowder.*) A wooden disk which crushes the mill-cake through the meshes of the sieves in granulating gunpowder.

Run'ner-stick. (*Founding.*) A cylindrical or slightly conical piece of wood, which acts as a pattern to form the upright part of the gate. Its point is stuck in the sand of the lower molding-box and the sand of the top part rammed around it. It is withdrawn before lifting the latter.

Run'ner-tack'le. (*Nautical.*) A luff-tackle applied to the running end of a rope passed through a movable pillow. See RUNNER.

Run'ning-block. (*Nautical.*) A hooked block which moves as the fall is hauled upon. In contradistinction to that block of a tackle which is hooked to a stationary object, and is called the *standing-block*.

Run'ning-bow'line Knot. (*Nautical.*) The end is taken round the standing part and made into a bowline around its own part.

Run'ning-bud'dle. (*Mining.*) See BUDDLE.

Run'ning-gear. (*Vehicle.*) The entire portion of the vehicle below the bed or body. Specifically, the wheels, axles, perch (if any), hounds, bolsters, and tongue.

Run'ning-hand. (*Printing.*) A font of type in imitation of running-hand.

This is Double Small Pica Running-Hand.

Run'ning-knot. See KNOT.

Run'ning-off. (*Founding.*) Opening the tap-hole of a blast-furnace to allow the metal to flow into the channels and thence to the molds.

Run'ning-part. (*Nautical.*) The hauling part or *fall* of a tackle; as distinguished from the standing part. See TACKLE.

Running-rein. (*Menage.*) A driving-rein which runs over pulleys on the headstall to increase its freedom of motion. It frequently passes over sheaves on the bit and returns up the cheek, so as to pull the bit up into the angle of the mouth. See the following patents: —

Run'ning-rig'ging. (*Nautical.*) Ropes for arranging the yards and sails, as —

Braces.	Inhauls.
Sheets.	Outhauls.
Halyards.	Brails.
Clewlines.	Leech-lines.
Bowlines.	Slab-lines.
Buntlines.	Tripping-lines.
Lifts.	Reef-tackle.
Tacks.	Tyes.
Downhauls.	Vangs, etc.

See RIGGING; also the above under their respective heads.

The term is in contradistinction to standing-rigging, which includes stays, shrouds, etc.

Run'ning-ti'tle. (*Printing.*) A line at the head of a page indicating the subject. *Headline.*

Run of Stones. A pair of mill-stones in working order. See GRINDING-MILL.

Run Through. (*Founding.*) A mold is said to be *run through* when a quantity of metal is made to enter at one gate and out at another, to remove sullage, air, etc., and make the casting solid. Also called FLOWING.

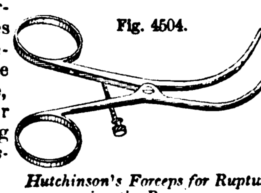
Run-up. (*Bookbinding.*) A fillet-mark which runs from head to tail on the back, without mitering with the horizontal cross fillets on the panels.

Ru'pert's Drop. A tear-shaped drop of unannealed glass. On breaking a piece from the point or tail the whole drops to pieces. This philosophical toy was first brought into notice, perhaps invented, by Prince Rupert, nephew of Charles I. of England.

"Mr. Peter did show us the experiment of the chymicall glasses, which break all to dust by breaking off a little small end; which is a great mystery to me." — PEPYS, 1662.

Rup'tur-ing-for'ceps. (*Surgical.*) An instrument used in rupturing the prepuce in cases of phimosis. It is introduced between the glans and the prepuce, distending the latter to rupture or forming a director for the *bistoury*.

Fig. 4504.



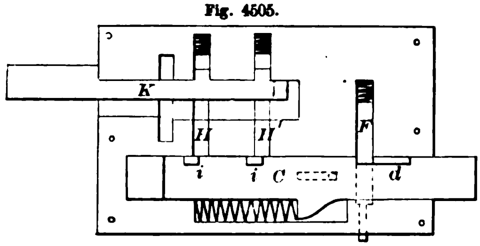
Hutchinson's Forceps for Rupturing the Prepuce.

Ru'ral Lock. (*Locksmithing.*) A cheap kind of lock with a wooden case. In Fig. 4505, K is the key having studs which lift the spring tumblers H H' out of the notches i i in the spring-bolt C. The spring-tumbler F is raised from the notch d when used as a latch.

The illustration shows a late invention, agreeing in all substantial respects with the locks of Egypt, 3,500 years ago, and those of Syria, yet used. See *A*, Fig. 2980, page 1339.

Rush-light. A tallow candle with a rush wick. Rush-lights are made in the same manner as dip-candles, a peeled rush being used for a wick. One

Fig. 4505.



Rural Lock.

narrow ribbon of the rind is left on the pith to hold it together. The rushes thus prepared are bleached and dried. They are dipped vertically in the melted tallow several times, as usual with dip-candles. Fifteen inches of rush-light is said to burn about 30 minutes. There are 1,600 rushes in a pound, and it takes 6 pounds of fat to dip them; the cost is thus very low. So says Gilbert White.

Rus'set. (*Leather-manufacture.*) The condition of leather when it is finished, excepting the operations of coloring and polishing the surface, either the *flesh* or *grain*, as the case may be, according to the purpose for which the skin is intended. This is called *russet-finish*, and in this condition leather is stored to be completed in *fair* leather, that is, uncolored, *black on the flesh* or *black on the grain*, for harness, boots or shoes, or for other purposes.

Rus'sia-duck. (*Fabric.*) Fine white linen canvas.

Rus'sia-leath'er. *Russia-leather*, also known as *jucten*, has a peculiar faculty for resisting moisture and the ravages of insects. As its name indicates, it was originally made in Russia, all kinds of hides being employed, but it is now made in Paris, where only goat and sheep skins are employed for the purpose.

The following is a summary of the Russian process: —

1. The dried skins are softened by steeping in water for from 5 to 12 days, according to temperature.
2. Unhaired by a lime bath, 8 feet in diameter, 7½ feet deep, and containing 185 pounds of slaked lime.
3. When the hair slips, the epidermis is scraped off on the beam.
4. The flesh side is cleaned by a fleshing-knife.
5. Steeping and beating to remove the lime.
6. The remainder of the lime neutralized and the hides swelled in a vat containing a fermented menstruum of rye-meal, 1,100 pounds; oatmeal, 450 pounds; salt, 6 pounds. Leaven to ferment.

The acetic acid developed *raises* the hide and counteracts the lime. An infusion of white gentian for 24 hours is sometimes used to get rid of the alkali.

7. The skins are steeped in an infusion of willow-bark.
8. The skins are placed in a pit, interstratified with layers of willow-bark and subjected to the pressure of planks and stones for from 15 to 28 days, the steep of the former process being employed.
9. The skins are *drawn*, fresh bark and solution being employed, and the skins packed into the pit, as before.

This is repeated till from 3 to 6 such changes have been made, according to the thickness of the skin.

10. The tanned skins are softened by maceration in a paste of oatmeal, 130 pounds; salt, 9 pounds; warm water.

This quantity serves for 150 skins.

11. The leather is cleaned and drained.
12. The leather is curried; a mixture of seal-calf oil 2, birch-bark oil 1, being employed, and carefully spread on to the extent of 9 ounces of oil to a skin.
13. The skins are stretched upon cords in an open shed and dried.

The French plan is as follows: —

1. Unhairing by a weak steep of lime and potassa.
2. Scraping on the beam.
3. Rinsing and fulling.
4. Washing in hot water.
5. Steeping 8 days in a farinaceous fermenting liquor.
6. Washed, and scraped with a fleshing-knife.
7. Immersed 48 hours in a paste of rye flour, fermented, and then diluted.
8. 15 days' steeping in a similar steep.
9. Washed previous to tanning.
10. Steeped for from 7 to 14 days in a warm infusion of willow-bark.

The skins are handled twice a day, and pressed for an hour each time.

11. Drawn and dried.
12. Curried. *a*. Treated with fish-oil; the hide being sheaved to equalize it, stretched and pommeled to supple it.

b. Grained by weighted rollers, whose surfaces have raised parallel and intersecting threads, so disposed as to give the desired pattern.

c. Treated with oil of birch on the flesh side.

13. Colored · Pommeled, slicked, and hard brushed.

The *red* color is given by alum and a decoction of Brazil and sandal woods; the *black* by a solution of sulphate of iron and sandal-wood. It is evident that the sandal-wood has something to do with the peculiar fragrance.

Rus'sia-mat'ting. Matting manufactured in Russia from the inner bark of the linden (*Tilia Europæa*). This matting is much used for packing, and the *bast* of which it is composed is used for tying up plants.

Rus'sia Sheet-i'ron. Sheet-iron made in Russia, and having a smooth, glossy surface of a purplish color, sometimes mottled. The process has been long supposed to be a secret, or it has been supposed that certain secret compositions are used. There may be some truth in this, and it does not appear that all the manufactories follow exactly the same order of treatment. The process has been observed by many travelers, among whom may be cited Pumpelly. One authority states that the metal is not subjected to any secret process, but that the iron is, in the first place, a very pure article, rendered exceedingly tough and flexible by refining and annealing. Its peculiar surface is a combined silicate and oxide of iron, produced by passing the hot sheet, moistened with a solution of wood ashes, between polished steel rollers.

Most of the attempts to imitate the Russia sheet-iron have been to give it a surface of carburet of iron.

Probably the most reliable description accessible is that given by Captain Meshtcherkin, a Russian mining-engineer conversant with the manufacture, to Dr. Percy.

According to this officer, the manufacture is principally confined to the eastern or Asiatic side of the Ural Mountains.

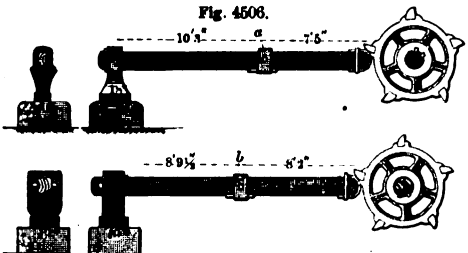
Charcoal iron from magnetic ore, carbonate, or red and brown hematite, and refined in the charcoal finery or the puddling-furnace, is employed. It should be rather crystalline than fibrous, and contain sufficient carbon to render it somewhat "steely." The puddle-balls are rolled into bars 5 inches wide by ¼ inch thick. Either one or two pairs of rolls, making not less than 50 revolutions per minute, are employed.

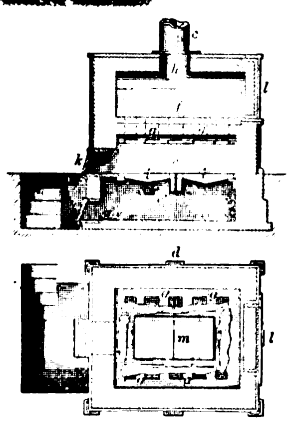
The sheets are extended under a trip-hammer (*a*, Fig. 4507) having a wrought-iron head faced with steel, and weighing about 60 poods (2,160 pounds); the anvil is of white cast-iron; both should be quite hard. Another trip-hammer (*b*), having a broader face, weighing 40 to 50 poods (1,440 to 1,800 pounds), attached to a lever fulcrumed more nearly at the center than the first, is employed in polishing.

The reheating furnace is shown in section at *c* and in plan at *d*. The fireplace *e* extends under the bed of the reheating-chamber *f* from end to end, and the gaseous products of combustion are carried into the chamber through five equal openings *g* on each side, and are finally carried off by the chimney *h*. *i* are the grate-bars, and *k k* the doors of the fireplace and ash-pit. *l* is the charging-door. This and the other doors are made as tight as possible, in order to prevent access of air to the plates being heated. Wood is the fuel used, and some of this also surrounds the pile in the reheating-chamber. The puddle-bars are cut into strips 29 inches in length, which are then heated to redness and cross-rolled some 12 or 14 times, until they are about 29 inches square. The sheets thus produced are then cleansed with a wet broom, arranged in packets of three, and passed through the rolls about ten times, powdered charcoal having been previously sprinkled in between them, and afterward sheared to the dimensions of 28 · 56 inches. Each sheet is then brushed all over with a mixture of birch-charcoal powder and water. From 70 to 100 sheets are made up into a packet *m*, which is bound with waste sheets and slowly heated for 5 or 6 hours in the furnace, surrounded by logs of wood, in order to consume any free oxygen present. The pile is then removed from the furnace and placed under the first hammer, being manipulated so that the blows fall upon it in successive rows from end to end. When it has been gone over about six

times in this way, it is removed and the sheets are alternated with some which are completely finished, making up a packet of from 140 to 200 sheets; these are subjected to the action of the second hammer, under which they are passed twice in a similar

Fig. 4506.





Russia Sheet-Iron (Hammers and Furnaces)

manner, which completes the smoothing process.

After the second hammering, the packet is opened, the surface of each sheet is again cleaned with a wet broom, and it is set in a vertical rack to cool: it is then sheared to the dimensions of 28 × 56 inches.

Professor Pumpelly, who witnessed the process employed in the works at Nijni Tagilsk, attributes the superiority of the Russian product in great part to the cleanliness observed and the skill and carefulness of the workmen. He states that when thin sheets are required, the rolling is repeated a third time in packages of four or six. The spotted sheets are separated into two inferior classes, and their diminution in value is deducted from the workmen's pay.

The fire-proof bricks used in lining the furnace are made of a fine quartz sand, merely sprinkled with lime-water before being molded and burned.

By another account, the rollers used are not formed in a lathe, but cast at once of the requisite smoothness and regularity in molds rubbed over with graphite. While the plates are being rolled, the edges are kept free from gaps by paring them with large shears. They are then placed in packs of from 10 to 20 on a moving bench, which passes them to and fro under a hammer of 40 poods' weight; both sides are alternately exposed to its action, and a man carefully brushes off the scales that are continually produced on the surface. The parings are mixed with half their weight of charcoal and converted into bar-iron.

Herbert Barry, late director of estates and iron-works of Vuicksa, thus describes the manufacture: —

The refined iron is hammered under the tilt-hammer into narrow slabs, calculated to produce a sheet of finished iron, 56 inches by 28 inches, weighing when finished from 6 to 12 pounds. These slabs are put in the reheating-furnaces, heated to a red heat, and rolled down to a sheet in three operations. These are subsequently hammered to reduce the thickness and confer the *glance*. A number of these sheets, having been again heated to a red heat, have charcoal-powder sifted between them. The pile, then receiving covering and a bottom in shape of a sheet of thicker iron, is placed under a heavy hammer; the bundle, grasped with tongs by two men, is pulled backward and forward by the gang, so that every part may be well hammered. When the redness goes off, they are finished, so far as this part of the operation goes, and have received some of the *glance* or necessary polish. They are then again heated and are rolled between cold finished sheets. They are again hammered, and, after this process, are finished as far as thickness and *glance* are concerned.

Thrown down separately to cool, they are taken to the shears and trimmed. Each sheet is then weighed, and after being thus assorted in weights, they are finally sorted into firsts, seconds, and thirds, according to their *glance* and freedom from flaws and spots. A first-class sheet must be like a mirror, without a spot in it.

The general weight per sheet is from six to twelve pounds, the larger demand being from ten to eleven pounds; but they are made weighing as much as thirty pounds, and may then almost be called thin boiler-plates, being used for stoves, etc.

The appearance of Russia iron is imparted to sheets (No. 22 wire gage) by dipping them while warm in a mixture, the consistency of molasses, of chalk, porcelain-clay, and graphite, in equal parts. When dried, they are further rolled and annealed, and afterward dipped in a pickle of 1 part sulphuric acid to 3 water till free from scales, then allowed to remain a short time in a lye of 1 potash to 20 water, filtered; afterward washed with clear water and smoked in an oven heated with light wood; the soot is burned off as the heat increases, and a carburet is formed on the surface with which it is closely combined. The plates are now gradually permitted to cool, and then hammered or rolled and tempered in a tightly closed chamber lined with fire-brick, when they may be again lightly hammered or passed through the polishing-rolls.

At the sheet-iron works in Brooklyn, an engine of 200 horse-power drives an automatic steam-hammer weighing seven tons. The rolled sheet-iron is greased and arranged in packages of thirty or more sheets. Each sheet is about 2½ feet wide and 7 feet long. The packs are then run into an oven and exposed to heat until the surface has attained the proper degree of oxidation. The packs are then transferred to the hammer, all the sheets in the pack being hammered at once. The anvil is movable, and the workmen change the position of the pack at each stroke of the hammer, so that every portion of the iron will be acted upon.

At the McKeesport Iron-Works, Wood's process is used. A heavy hammer falls vertically on the sheets with rapid blows as they are passed over an anvil, the face of the hammer and the anvil being pitted with small indentations. It is the passage under this hammer that does the planishing, giving the even surface, mottled finish, and density of fiber which characterize the Russian. The charcoal iron is rolled into bars and cut, the scale is removed, after which it is rolled into sheets of different thicknesses, then cold rolled, then heated to a cherry-red, and passed under the planishing-hammer three sheets at a time.

The following are condensed descriptions of United States patents for modes of making sheet-iron similar to the Russian:

No. 2,813, Wood, 10, 12, 1842. Rolled in usual manner, but left thicker; oxide removed by acid; cleaned and dried; coated with linseed-oil; two such plates placed between two others; the pack heated to a cherry-red and rolled repeatedly till the gloss is obtained.

No. 2,824, Guilford, 22, 10, 1842. Scale removed by acid; washed and dried; subjected to mutual friction in a box with lid and stampers; heated to blue color; passed, while hot, through hardened and polished rolls.

No. 8,048, Wood, 15, 4, 1851. Similar to No. 2,813, but the pack is rolled between shield-plates. The latter eventually become inside plates, being scaled, oiled, heated, and rolled as the others. Smoothed and glazed by cold rolling between shield-plates.

No. 9,075, McCarty, 26, 6, 1852. Plates are scaled by acid bath and zinc in a lead pan during effervescence; washed and dried; heated to cherry-red in a lead bath; rolled while hot; mottled marks given by hammer-dressing on the rolls.

English patent, No. 14,244, 1852. The sheets are rolled, piled in fours, and rerolled, trimmed, heated, rolled in packs, heated, packed (20 sheets) with intervening charcoal, hammered with a 250-pound hammer; unpacked, packed (40 sheets) without charcoal, one hot and one cold sheet alternately; hammered by a 900-pound hammer; annealed and trimmed.

No. 10,047, McCarty, 27, 9, 1853. Planished rolls to give mottled marks to the iron sheets.

No. 10,482, Pomeroy, 31, 1, 1854. Iron plates painted with a composition of graphite, charcoal, and soot or boneblack, diluted with anything and put on with a brush; heat and roll.

No. 21,692, Morris, 5, 10, 1858. Making a mottled, chilled-iron roll for rolling sheet-iron. The rolls are chilled, turned, polished; dotted with wax according to taste; immersed in acid bath to etch in the intervals; placed in a lathe and rubbed with emery and oil to take off the sharp edges.

No. 21,772, Morris, 12, 10, 1858. Sheet-iron of carefully selected and prepared metal is passed between mottled rollers (as above), placed in a muffle, heated to redness in a furnace; made into a pack of ten, with intervening charcoal; the pack placed on an anvil, which is made to travel to and fro beneath a gang of hammers; reheated; rehammered; annealed.

No. 21,817, Chandler, 19, 10, 1858. Sheets are rubbed with or dipped into a paste of clay or peat, and metallic oxides; rolled, cleaned, made into a pack, and rerolled.

No. 31,184, Morris, 22, 1, 1861. Rolled sheets are coated with oil, boxed, placed in a muffle, and heated to 900° Fah.; hammered in the pack to combine the carbonized scale and form a carbureted surface.

No. 32,341, Wood, 14, 5, 1861. Rolled sheets are annealed at a dull white heat; cooled; rolled between corrugated rolls to break scale, then between plain rolls; no acids; coat surface with oil and graphite; heat to bright red; roll in packs; rolls covered with oil and graphite.

No. 33,341, Wood, 3, 9, 1861. Rolled plates are warmed and dipped in a bath of water, chalk, porcelain-clay, and graphite; withdrawn and dried; pack of ten plates heated to bright red and rolled; acid bath to remove scale; alkaline bath to develop color; water bath; dried; heated in a smoky oven to cover sur-

face with carbon deposit, which becomes embodied in the iron; cooled; planished or rolled; tempered.

No. 33,214, Riess, 3, 9, 1861. Rolled plates are dipped in a bath of chalk, porcelain-clay, and graphite; dried, packed, heated, rolled, and annealed.

No. 33,844, McDaniel and Harvey, 3, 12, 1861. Vacuum pressure in the removal of acid liquor, and subsequent alkaline treatment.

No. 34,294, Dixon, 4, 2, 1862. Rolled plates scaled by acid bath; washed with adhesive, or rye-water; swabbed at less than a red heat with an enamel composition; kept at that heat for ten hours in an oven; sheets placed in an annealing-box with interposed charcoal-dust, and heated; rolled in packs and annealed.

No 46,974, Pratt, 14, 2, 1865. Sheet-metal immersed in acid bath at a prescribed heat; removed, scrubbed, and immersed in alkaline bath; brushed with rotary brushes while wet; heated to dryness; immersed in oil bath at 100° to 150° Fah.; dripped, and passed between polished steel-rollers; buffed by leather-rollers and chalk-dust; colored over charcoal furnace.

No. 48,918, Ells, 25, 7, 1865. Sheets annealed; placed loosely in a cast-iron box, with scale of oxide, animal charcoal, coke, lime, or other decarbonizing or cutting agents; agitated while heated in the furnace.

No. 50,203, Grey, 26, 9, 1865. Heats the sheets previous to finishing; cools to a point below cherry-red; rolls without removing scale; repeats operation.

No. 52,647, Perkins, 13, 2, 1866. Cleans and brightens mechanically; then heats in an oven to develop color.

No. 53,476, Perkins, 27, 3, 1866. Sheets packed with intervening iron turnings; heated, rolled, annealed.

No. 53,253, Allen and Hinsdale, 20, 3, 1866. A fagot of iron has top and bottom steel-plates; heated, rolled into a bar; bar rolled into sheets; oxide removed by acid bath; washed; a pack of ten heated to redness and rolled.

No. 56,759, Jones, Spaulding, and Perkins, 31, 7, 1866. The wrought-iron melted in a crucible with nitrate of lead, muriate of antimony, bone-dust, and graphite; stir; remove flux from the top; run into molds and roll as usual.

No. 61,034, Wood, 8, 1, 1867. After removing from the alkaline bath, and washing as usual in hot water, the plate is dried and heated in an oven below redness; dipped in a bath of oil and turpentine.

No. 63,805, Miller, 16, 4, 1867. The rolled sheet, before a final rolling, is heated nearly to welding point by gas-jets, above and below the plate, just before entering between the finishing-rollers.

No. 77,111, Shaw, 21, 4, 1868. The heated iron, or the rolls, are mopped with a composition of graphite, animal fat, soda, and water.

No 81,903, Hinsdale, 8, 9, 1868. The bar-iron is scaled; washed; dipped in a bath of clay 100, lampblack 1, prussiate of potash .5; heated and rolled; the sheet-iron is dipped in same composition and rerolled.

No. 88,092, Atkins, 23, 3, 1869. Roll into sheets, scale with acid, neutralize with lime-water, oil; lay up the iron in packs with intervening charcoal and marble dust; raise to a red-heat, roll singly; reheat, and roll in pairs, and so on; rolling till cold to develop polish; heat in packs to anneal; roll, and cool slowly.

No. 95,554, Barker, 5, 10, 1869. Roll; remove scale by acid; wash; potash bath, in which they remain till rolled; roll in packs, cold; mottled rolls, made by a peculiar process of chill casting.

No. 98,364, Fields, 28, 12, 1869. Iron is of Franklinite 100, good pig-iron 400. Sheet-iron is scaled; dipped in a bath of flour of zinc 1, graphite 1, tallow enough to make consistence of cream, when melted; a pack of three sheets is placed beneath a steam-hammer with a hard-wood face; the anvil having a similar face; grain of wood vertical.

No 103,323, Grey, 24, 5, 1871. Scale removed by an acid bath and subsequent heating on racks in an oven to raise the scale in blisters. A thin, tenacious oxide forms on the surface and is preserved. Rolled cold, first singly, then in packs; annealed.

No. 103,577, Craig, 31, 5, 1870. Plates are built into packs with intervening charcoal-dust; heated nearly to welding heat; rolled in packs; reviving the metal of the superficial oxide.

No. 114,956, Marshall, 16, 5, 1871. Scale removed by *saline* bath and furnace heating; dipped in lime-water; heated to cherry-red and rolled in packs; anneal.

Rus'ti-ca'tion. (*Masonry.*) A general name for that species of masonry in which the surfaces of the stones are left rough, and the several courses and the stones in each course are distinctly marked by sunk joints or grooves, either chamfered or otherwise cut.

Contrary to the import of the name, *rustication* admits of great variety of expression and very elaborate treatment. The faces of the stones are sometimes vermiculated or otherwise made rough; the tooling occupying a panel surrounded by a smooth border terminating in the arris of the chamfer, which constitutes the projection of the face above the surface of the sunk joint.

The varieties of *rusticated* work are known as *vermiculated*, *punctured*, *frosted*, *stalactited*, *chamfered*, according to the character of the ornamentation of the face, or some peculiarity of the salient edge.

Vermiculated has contorted tooling distantly resembling worms, from which its name is derived.

Punctured is picked full of holes in lines or irregularly.

Frosted has a fine, even roughness, distantly resembling hoar frost.

Stalactited has ornaments like icicles, in imitation of those natural deposits from which the name is derived.

Chamfered; the salient panel has a beveled edge, having an angle of 135° with the face.

Rus'tic Cham'fered Work. (*Masonry.*) The chamfered edges of the face of the ashlar have an angle of 135° with the face, so that at the joint the beveling will form a right angle.

Rus'tic Joint. (*Masonry.*) A sunken joint between stones, either square or chamfered.

Rus'tic Or'der. That kind of building in which the faces of the stones are *hatched* or *nigged* with the point of the hammer.

Rus'tic Quoin. (*Masonry.*) The ashlaring at the corner of a house or wall, projecting from the face, and laid alternately stretcher and header with rustic joints.

The quoins may have edges chamfered to an angle of 135° with the face of the building, so as to make a right angular joint. The faces of the stones are usually tooled.

Rus'tic Work. 1. (*Wood.*) An imitation of rough or primitive work. Furniture for summer-houses and lawns, made of limbs of trees, taking advantage of natural crooks and crotches to form the shapes desired. See GARDEN-SEAT, Fig. 2159.

2. (*Stone.*) Masonry jagged over with a hammer to an irregular surface. A margin around the joints is recessed. This is known as the *margin-draft*. When the face is made in imitation of ice, it is called *frosted rustic-work*. When contorted, it is called *vermiculated* work.

Rust-joint. (*Metal-working.*) A joint made water-tight by a compound which oxidizes or sets on exposure to the air; as the following: —

Quickly setting. Sal-ammoniac in powder, by weight, 1 part; flour sulphur, 2 parts; iron borings, 80 parts. Make to a paste with water.

Slowly setting. Sal-ammoniac in powder, by weight, 2 parts; flour sulphur, 1 part; iron borings, 200 parts.

The latter cement is the better one if the joint be not required for immediate use.

Ru-the'ni-um. Equivalent, 52.1; symbol, *Ru.*; specific gravity, 11.4; nearly infusible. It is of a gray color, hard and brittle. A rare metal found associated with platinum. It was discovered by Claus in 1845.

Rynd. (*Grinding-mill.*) The ball which supports the runner on the head of the spindle. See BALANCE-RYND, *F F*, Fig. 536.

S.

Sa'ber. (*Weapon.*) A sword having a curved blade, specially adapted for cutting.

Three kinds are in general use in the armies of Europe and America.

That for heavy cavalry has a slightly curved, heavy blade.

The light-cavalry saber has a lighter blade somewhat more curved.

The horse-artillery saber is still shorter, lighter, and more curved, and has but one branch to the guard.

Sa-bot'. 1. A wooden shoe made of one piece hollowed out by boring-tools and scrapers.

We learn from Cicero that parricides at Rome were fitted with a pair of wooden shoes before they were sewn up in the sack in which they were drowned.

Sabots are cherished by the whole Gallic race, and might be used with advantage by other people for occasional protection on sloppy pavements and on wet ground, while about the duties of the kitchen, laundry, and kitchen-garden.

Sabots in France are divided into the *gros* and the *fins:* the former being coarse and sold at 14 cents per pair; and the latter at 40 cents, trimming extra.

The kinds of wood used, beginning with the commoner varieties, are willow, poplar (Lombardy), beech, birch, aspen, ash, hornbeam, walnut.

The wood is cut when it attains a certain size, and is sold on the spot by auction. The *sabotiers* attend in person and work up their purchases on the spot, giving the crude form to the *sabots*, which are afterward seasoned, and are then finished, carved, and blacked in Paris or some other mercantile center. The seasoning of the wood takes about twelve months. *Gros sabots* are sometimes dried and smoked to expedite the seasoning, and are finished and sold by country makers and venders in their own communities.

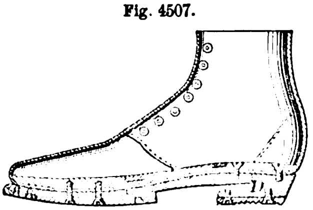
The timber is cross-cut in lengths for shoes and riven into blocks. They are rough hewn by a hand-axe, the operator being called a *tailleur*, or cutter. Another workman, the *paroir*, or parer, now takes them. The cutting-tool has a bent blade, a short handle, and its point has a hook which engages a ring attached to the bench. The block is held in the left hand and steadied by certain indentations and prominences on the bench while it is being pared, assuming somewhat the shape of a *last*.

The third workman is the *creuseur*, or scooper, who works with augers and spoon-shaped cutters, called *cuillères*. The blank is fixed by wedges between posts on the bench, the heel presented toward the workman, who scoops and gouges out the interior, testing his work by gages.

After drying, they are carved, painted, and trimmed.

Fig. 4507 is a compromise; a shoe with double wooden sole, having a double flexible shank *D* interposed between the toe and heel parts.

Fig. 4507.



Sabot.

2. (*Ordnance.*) *a.* A circular block, usually of wood, hollowed out and fixed by tin straps to a projectile, so as to maintain its proper position in the bore of a gun, to prevent its upsetting in loading, wobbling in discharging, and to decrease windage by occupying the bore more perfectly than can be done by the projectile itself.

b. A metallic cup or disk fixed to the bottom of an elongated projectile, so as to fill the bore and take the rifling when the gun is discharged.

Sa-bo-ti-ere'. A French apparatus for making ices. It consists of an outer pail of wood and an inner vessel of metal, to contain the cream to be iced. In the intervening space is a mixture of pounded ice and salt, or of sulphate of soda and hydrochloric acid. The contents of the inner vessel are agitated by a handle, and the frozen cream is occasionally scraped down.

Sab're-tasche. A leathern pocket suspended on the left side from the sword-belt of a cavalry officer.

Sac'cha-rom'e-ter. A hydrometer graduated to indicate the amount of sugar in worts and other saccharine solutions. Bate's is generally used in England.

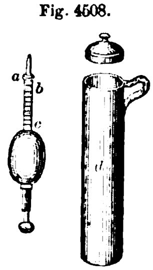
It consists of a brass ball with a cylindrical stem, graduated into 30 parts, each corresponding to $\frac{1}{1000}$ of the specific gravity of water, the relative length of the divisions being such as to compensate for the increased volume of the submerged portion as it sinks in the liquid. Tables are prepared, showing the percentage of sugar contained in worts of specific gravities corresponding to the indications of the scale.

The optical saccharometer is a form of polariscope devised by Mitscherlich with special reference to testing sugars by polarized light. It is provided with a graduated circle for measuring the angles of polarization, which serve as a basis of comparison for the different qualities.

The saccharometer usually employed in this country and on the Continent of Europe is Baumé's. It consists of a bulb having a smaller bulb beneath, weighted with mercury or shot, and a graduated stem above. In water it sinks to a certain mark, but in sirup it rises in proportion to the density of the latter. It is a *hydrometer* with marks which render it specially applicable to the uses of determining percentages of sugar in solution or in sirups. The *alcoholmeter*, and others of this class differ in their graduations, which render them specially applicable to a specific class of liquids or solutions. A degree on the scale of the saccharometer marks 0.019 parts of sugar in the sirup. Thus, if the saccharometer, floating in sirup, marks 10° B., we have $.019 \times 10 = .19$, and know that there is 19 per cent of sugar in that sirup. If the sirup is boiling, however, it is lighter than when cold by about 3°. Thin juice is of the same density, hot or cold. See HYDROMETER.

A saccharometer commonly employed by brewers in England for testing worts is of copper, and has a flat stem having a projection *a* at the upper part to receive a series of weights marked 1, 2, 3, 4, 5, 10, 20, 30. At the temperature of 62° Fah., the instrument sinks in distilled water to the mark *b*. A barrel (36 gallons) of pure water at this temperature weighs 360 pounds. If the instrument be placed in a liquid weighing 361 pounds to the barrel, it will sink only to the mark *c*. The distance between these two marks is divided into 10 equal parts, each equivalent to a difference of $\frac{1}{10}$ of a pound in the weight of the liquid. The number of pounds and tenths which a barrel of wort weighs over 360 is ascertained by placing weights over the projection sufficient to sink the stem to one of the points *b c* or one of the intermediate graduations. Thus, if the weights 10, 5, 2 be required to sink the instrument to the mark numbered 3 on the stem, the weight of the wort will be 377.3 pounds per barrel. *d* is a vessel for containing the wort to be operated on.

Fig. 4508.



Wort-Saccharometer.

One mode of detecting the character of a saccharine solution is by the polarization of light, observation being made of the extent to which a given volume of a saccharine solution twists a ray of polarized light.

By peculiar operations, the presence, quantity, or relative proportions of cane and grape sugar may be determined. Both cane and grape sugar twist the ray to the right, but the former alone has this power inverted on ebullition with hydrochloric acid. This furnishes experimental data for the quantities of each present

Another mode consists in converting the cane-sugar into grape-sugar by boiling with dilute sulphuric acid for two or three hours and then heating with solution of potash or soda, and comparing the depth of color of the resulting dark brown

liquid with similar liquids prepared from known weights of sugar.

Grape-sugar will also reduce an alkaline solution of tartrate of copper with precipitation of orange-yellow suboxide of copper. This reaction is perfectly definite, and may be applied in the estimation of grape or cane sugar, or both.

Sack. A bag of leather or fabric, used for holding grain, salt, coal, and innumerable other articles.

The word *sack* is said to be the only one which survived the confusion of tongues at Babel, being the same in all languages. Each man, as soon as he found something was going wrong, called for his *sack* to carry home his tools in.

Sacks are made in Western India from the inner bark of the *Antiaris saccidora*. A section of the tree about one foot in diameter is cut off, of the length required for a sack; soaking and pounding loosens it, and it is stripped off as a squirrel is skinned. Sew up the end, and the thing is complete. The bark is also used, pounded thin, cut up to the pattern required, and sewn together like any other fabric.

The Spanish wine called *sack*, which would appear to have formed the principal nutriment of Falstaff, is said to derive its name from the leathern sacks containing it; others, however, think it a corruption of *sec* (dry).

Sack'but. (*Music.*) *a.* An ancient wind-instrument mentioned in Daniel iii. 5 – 15.

b. A wind-instrument of the trumpet species. It is of a low pitch, and the tone is modulated by lengthening and shortening by means of sliders. See TROMBONE.

Fig. 4509.

Sack-Hoist.

Sack'cloth. (*Fabric.*) Coarse stuff for sacks.

Sack-fil'ter. See BAG-FILTER, page 209.

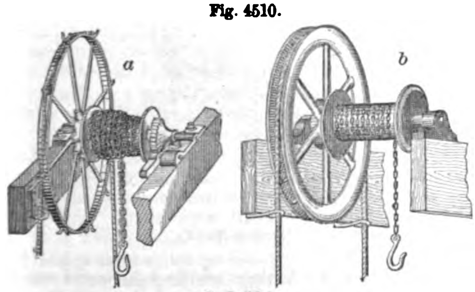
Sack-hoist. An adaptation of the wheel and axle to form a continuous hoist for sacks and packages in warehouses, etc. In Fig. 4509, the wheel is turned by pulling on the endless chain *a*; the links of the hoisting-chain *b* engage sprockets on the axle; while one end is ascending with a sack attached, the other descends to receive another sack.

The apparatus may have a friction-brake and a ratchet and pawl to prevent the weight falling should the hoisting be suspended for a moment.

The *dispatch-hoist* (*a*, Fig. 4510) is specially intended for sacks of corn, bales of leather, and other articles not liable to injury if let down quickly. The load remains suspended just where left, until released by reversing the action of the main wheel. The descent can be regulated by this wheel, the rope remaining stationary.

The *safety-hoist* (*b*) is adapted for goods requiring care in lowering. The main wheel, on being reversed, causes the load to descend at a moderate speed, and can be kept going by an occasional pull at the rope. If the load be allowed to run, it will gradually check itself until it stops. If the rope is suddenly "let go" while lifting, the load will remain suspended just where it is. The principle of this latter is found in the differential pulley.

Fig. 4510.

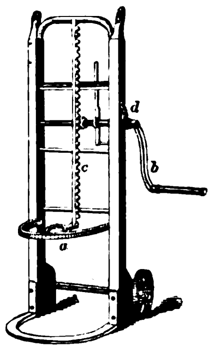


Sack-Hoist.

Sack'ing. (*Fabric.*) A coarse hempen or flaxen fabric, made for bags and bed-bottoms.

Sack-lift'er. The apparatus (Fig. 4511) is used as a lifter and a truck. It is turned up on end to receive the full sack, which is placed on the movable platform *a*; it may then be wheeled to the wagon or storehouse, and the sack raised shoulder-high by turning the winch *b*, which operates the rack *c* attached to the platform. A pawl *d* prevents the descent of the platform when the winch is let go.

Fig. 4511.



Sack-Lifter.

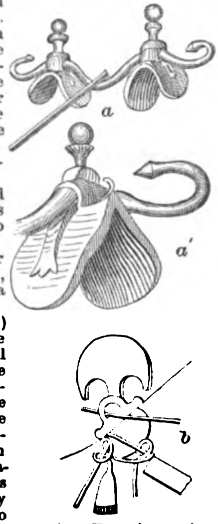
Sac'ris-ty. (*Architecture.*) That apartment of a church in which the consecrated vessels and the vestments of the clergy are kept.

Sad'den-ing. (*Dyeing.*) A method of applying several mordants to cloth to be printed.

Sad'dle. 1. (*Saddlery.*) A seat or pad to be placed on the back of an animal to support the rider or the load. Besides the ordinary kinds, the man's saddle, and the *side*-saddle for women, there are *cart, gig, pack, ambulance, camel*, and *ox* saddles. The camel is used in Asia and the northern part of Africa. The ox is the ordinary beast for riding and for burdens in the interior of Africa, as witness Livingstone, Speke, Grant, Baker, Barth, Chaillu, Reade.

The earliest saddles on record are those of Egypt (*a*) and Persepolis. They were not for riding, but were analogous to our harness-saddles, except in their position. They rested on the withers of the horses, and were secured in place by belly and collar bands. They were attached to a yoke which passed over the shoulders of the horses, and at its midlength was attached to the pole or tongue of the chariot. The saddle had a hook for the bearing-rein, and had a single trace, on the side of the horse against the pole. See page 1062.

Fig. 4512.



Ancient Egyptian and Persian Saddles.

The Persian saddle (*b*) was substantially the same.

Equestrians used cloths secured by girths. The Persian seat-cloths were abundant, but they had no *tree*.

The saddle referred to in our translation of the Bible, 1890 B. C., and subsequently, was doubtless a cloth fastened by a surcingle.

The saddle of Alexander (320 B. C.) was without a tree or stirrups; the cloth on which he rode was secured by girth and breast-band. The equestrian represented on the Etruscan vase of Cardinal Gualteri rode on a naked horse. Even after the introduction of cloths, it was esteemed manly to do so. The Roman cavalry, until the time of Nero, paraded and reviewed without cloths or coverings, in order to show plainly the condition of the animals. Nero added cloths for show, and in the time of Alexander Severus (A. D. 222) they were splendidly accoutered. Pliny states that one Pelethronius first introduced seat-cloths. Xenophon speaks of the gorgeous and excessive coverings of the Persian horses. The Germans despised them after they were fully adopted in the Roman army. What may be termed *pad-saddles*, of leather, are mentioned A. D. 304.

The invention of the saddle has been attributed to the *Selians*, a people of ancient Franconia. Hence, perhaps, the Latin *sella*.

Leaving a doubtful passage in Zonaras referring to the fall of Constantine the Younger (A. D. 340) from the *sella*, which may mean a *saddle*, but more probably means his seat on horseback, we find the saddle fully described in the time of Theodosius. In the code of this monarch, published about the year 385, there is a rescript which directs that the weight of a saddle and bridle for post-horses should not together exceed 60 pounds, — a very good order.

The Emperor Leo I., in the fifth century, interdicted the use of pearls and jewels in the decoration of saddles.

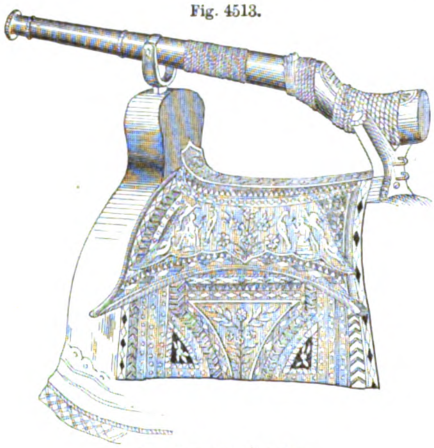
Mauritius, in the sixth century, ordered the saddles of the cavalry to be covered with fur.

It appears that the Greeks and Romans mounted from what we call the *off* side of the horse.

The difference between a pad and a saddle consists in the presence of a tree in the latter. The monuments and coins show a gradual change, from the mere cloth to a padded seat and surcingle; then appear rolls, which may be considered incipient pommel and cantle. The word in early use was *ephippium;* it was afterward *sella*. Perhaps the latter was the true saddle.

The saddle was known in England among the Saxons, and was probably introduced by the Romans during the latter portion of their occupation. According to Strutt, who is, perhaps, the best authority, the Saxon and Norman ladies rode sideways, as at present. Other authorities state that the side-saddle was introduced by Anne, daughter of the king of Bohemia and queen

Fig. 4513.



Camel Saddle and Gun.

of Richard II. Previous to that time, a lady rode on a pillion behind her cavalier or a servant, or else in the masculine manner still customary in some parts of Europe.

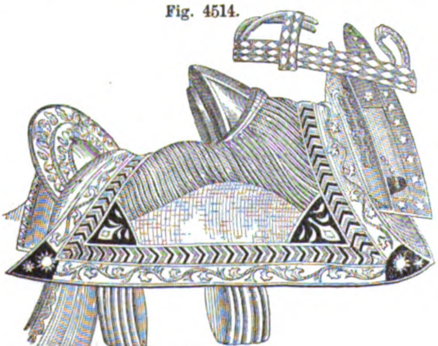
Queen Elizabeth rode on a pillion behind the Lord Chancellor from London to Exeter, and this was common till the beginning of the present century.

Stirrups were invented about 200 years after riding-saddles. See STIRRUP.

The Tartar saddles are of wood, carefully adapted to the shape of the animal's back. The fitting is done by a knife, by successive parings and trials.

The Japanese saddle is of wood, with a cushion underneath, and a cloth at the rear, covering the horse's loins. It is secured by a girth, a *poitral*, or breast leather, and a crupper. The civilian traveler uses a pair of saddle-bags, an *adofski* or trunk laid over them, and sits upon a cloth spread over all.

Fig. 4514.



Camel's Saddle.

The dignitary or cavalry soldier rides upon a saddle with high ridges for pommel and cantle. The stirrup is shaped like a shoe-sole, and is open at the side. The stirrup-leathers are short. The rider mounts from the *off* side.

Fig. 4513 is a view of a camel's saddle and gun, from Lahore in the Punjaub. The drawing is from the article which was contributed from India to the London Exhibition of 1851.

Fig 4514 is also a camel's saddle from Lahore.

The Icelandic side-saddles, like those of some other nations, resemble an ordinary chair-seat with a foot-piece, as in the annexed cut from a drawing by J. Ross Browne.

Fig. 4515.

Icelandic Side-Saddle.

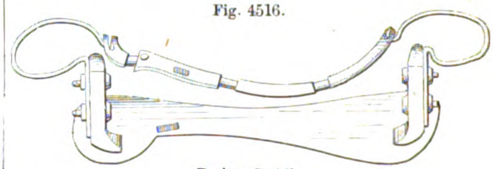
The Prussian cavalry-saddle has a wooden tree in two parts, attached at the ends by cast-iron forks, forming a high pommel and cantle. The seat is covered with a padded leathern cushion. A padding of straw is used with the saddle.

Among some nations, as the Hungarians, Mexicans, and others, the saddles are extremely elaborate. An enumeration of the parts and appurtenances of a Hungarian saddle may be interesting: —

Tree.	Stirrups.
Straining-leather.	Stirrup-leathers.
Seat.	Carbine bucket and strap.
Lacing-thongs.	Carbine stay-strap.
Holster.	Baggage-straps.
Girth.	Cloak-straps.
Girth-strap.	Horseshoe-case.
Pilch (*pelt*) fur covering.	Shabraque strap.
Flaps.	Wanty, for binding on a load.
Crupper dock, body, and strap.	Blanket, folded beneath the tree.
Breast-plate.	

The parts of a saddle are the *tree* or foundation, the *padding*, *skirts*, *seat*, *girth*, *stirrup-strap*, and *crupper-loop*.

Fig. 4516.



Spring-Saddle.

The tree consists of *pommel*, *cantle*, and *side-bars*. To the latter are attached the *stirrup-loops;* the *crupper-loop* is attached to the cantle. See SADDLE-TREE.

In Fig. 4516, the seat is suspended above the tree from springs attached to the pommel and cantle

Fig. 4517.

Riding-Saddle.

Fig. 4517 has an elastic seat *H* strained between the pommel and cantle, and has an additional support by transverse, arched springs *G G*, whose ends rest upon the side plates.

Fig. 4518 is a harness-saddle.

Fig 4518.

Harness-Saddle.

2. (*Nautical.*) A piece or block hollowed out to fit another portion, which is seated thereon, as —

a. The block on a yard-arm which receives the studding-sail boom.

b. The block on the upper side of the bowsprit to receive the heel of the jib-boom. It is situated at a distance one third of the length of the jib-boom inward from the outside of the bowsprit-cap.

3. (*Ordnance.*) A support on which a gun is placed for bouching.

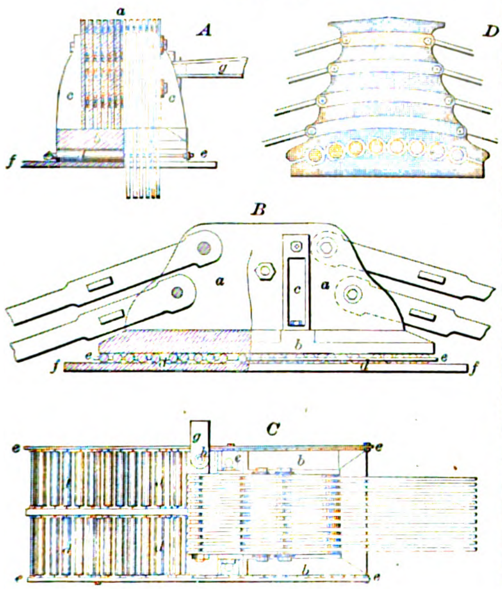
4. (*Railway.*) *a*. The bearing or *brass* resting on the journal of a car-axle in the axle-box. See CAR-AXLE BOX.

b. A chair or seat for a railway-rail. See RAILWAY-CHAIR.

5. (*Machinery.*) A block with a hollowing top to sustain a round object, as a rod upon a bench or bed.

6. (*Bridge-building.*) A block on the summit of a pier over which suspension cables pass or to which they are attached. In the illustration, *A* is a section, *B* an elevation, and *C* a plan of the saddles of Charing Cross Bridge. The plates *a a*, to which the upper and lower chains are connected, rest upon a cast-iron plate *b*, to which they are fixed by the standards *c c*; this plate is supported upon rollers *d d* held in place by a frame *e e*. The lower plates

Fig. 4519.



Saddle for Cable of Suspension Bridge.

f f, on which the rollers run, are supported on a platform of timber and iron girders, by which the weight is distributed over four pillars of brickwork, which support the whole. There are two saddles on each pier, connected together by a bar *g* working on a center at *h*, so that while the saddles are maintained at a proper distance apart, they are allowed the requisite freedom of motion.

D is a saddle on the apex of one of the piers of the Menai Suspension Bridge. It is of cast-iron, resting on wrought-iron rollers with brass boxes, so that as the temperature varies some play is allowed to the chains. There were 16 chains, each weighing 120 tons 299 pounds. Total, 3,876,784 pounds. The bridge was built over the Menai Straits by Telford, in 1829. Each of the eight cast-iron saddles weighed 3,248 pounds, and the cast-iron bed-plate on the apex of each pier, supporting the saddles at that end of the catenary, weighed 46,080 pounds.

Sad'dle-back. (*Building.*) A coping with a double slope to shed rain.

Sad'dle-bags. (*Saddlery.*) A pair of bags or pouches, connected by a leathern seat, carried on the back of an animal, being laid over or behind the saddle.

Sad'dle-bar. 1. (*Carpentry.*) An iron bar crossing a window-frame and serving as a stay for the *fretwork* or glass secured in leaden *cames* or bars. See FRETWORK.

2. (*Saddlery.*) The *side-bar*, *side-plate*, or *spring-bar* of a saddle-tree, one on each side connecting the pommel and cantle.

Sad'dle-bow. (*Saddlery.*) The upper, front part of a saddle-tree formed of two curved pieces united so as to form an arch. The *pommel*.

Sad'dle-cloth. (*Saddlery.*) A cloth attached to a saddle and extending over the loins of the horse. A *housing*. A *shabrack*.

Sad'dle-girth. (*Saddlery.*) A band of leather or webbing which is attached on one side of the saddle, and, passing under the horse's belly, is secured to the other side by a buckle and strap, serving to keep the saddle in place.

Sad'dle-joint. A form of joint for sheet-metal, in connecting adjacent boiling-pans or adjoining strips in roofing. One portion overlaps and straddles the vertical edge of the next.

Fig. 4520.

Saddle-Joint.

Sad'dle-nail. (*Saddlery.*) A short nail having a large, smooth head, used in making saddles.

Sad'dle-rail. (*Railway Engineering.*) A railway rail which has flanges straddling a longitudinal and continuous sleeper. See RAIL.

Sad'dle-reed. (*Saddlery.*) Small reeds used in the place of cord to form the edges of gig-saddle sides.

Sad'dle-roof. (*Building.*) A double-gabled roof.

Sad'dler's Knife. (*Saddlery.*) A *half-round* knife. The semicircular knife, so familiar as a leather knife, is shown in the paintings of ancient Egypt.

Fig. 4521.

Saddler's Pinchers.

Sad'dler's Pinch'ers. (*Saddlery.*) A tool somewhat resembling the shoemaker's, but heavier, and having straighter grasping jaws. It has a lug on its lower side, serving as a fulcrum in drawing nails, etc., and straining leather tightly into position for tacking or stitching.

Scraper.
Clipping-machine.
Hemp head and reins.
Cleaning materials, viz. : —
Soap.
Oil.
Dye.
Carriage-candles.
Blacking.

Sad'dler-y-hard'ware. (*Saddlery.*) A general name for all metallic goods used in making saddles and harness.

Sad'dle-tree. (*Saddlery.*) *a.* The frame forming the support of a saddle ; usually made of wood. The parts are secured together by tenons and mortises, and held in place by a covering of canvas or wet raw-hide, which is tacked tightly and then shrunk by drying.

The tree consists of a *pommel*, *cantle*, two *side-bars* ; two *stirrup-bars* are added and iron staples for the valise, if required.

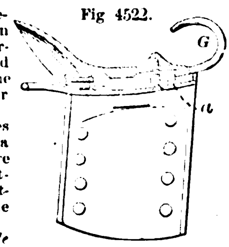
The kinds are numerous, according to the purpose, taste, or fashion of saddles. We may enumerate —

Spanish.
Half-Spanish.
English.
Side.
McClellan.
Somerset.
Jockey, etc.

The tree is the basis of the saddle, and determines its shape, as well as to a large extent its efficiency. It is usually of beech, strengthened by iron plates : the *gullet-plates* under the head, plates over the head and under the cantle.

Kelly, 1810, made saddle-trees of whalebone lined in part with metal

Fig 4522.



Harness Saddle-Tree.

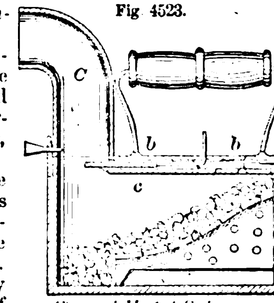
Thompson, 1825, made a saddle-tree of steel or iron. Bielefeld, in 1855, one principally of gutta-percha. Brooman, 1865, of wood and leather. Another man, in 1865, one of papier mache and horsehair combined and molded.

As a means of making saddles adjustable to fit different horses, a Mr. Smith, in 1786, made the fore points of steel springs with gullet-plates set out or narrowed by set-screws. Dunn, in 1791, made jointed gullet-plates.

b. The frame of a *harness-saddle* or *gig-saddle*. In the example, the check-rein hook *G* is secured between the seat and the tree by means of a lug or projection *a* passing through the leather at the upper surface of the tree, combined with a screw, flush with the under surface ; and another screw passes through a lip placed at the rear of the tree and into a pendant projection, for the purpose of securing the rear portion.

Sad'i-ron. An iron with a flat face, used for smoothing clothes. A *flat-iron*. A *smoothing-iron*.

Fig 4523.

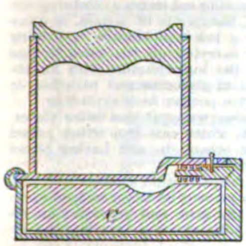


Charcoal-Heated Sadiron.

Besides the ordinary laundry-iron are many others, heated by incandescent charcoal, by iron-heater, by gas, lamp, etc.

In Fig. 4523, the body of the iron is hollow and has a perforated curved plate supporting the fuel. The top is formed by two plates *b c*, one of

Fig. 4524.



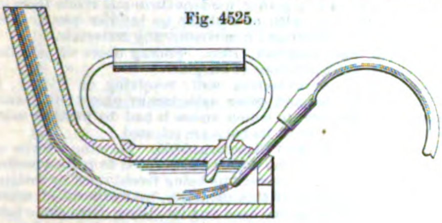
Heater Sadiron.

which serves as a damper. The products of combustion are carried off by the flue *C*.

In Fig. 4524, the cover is hinged at the back and held shut by a spring-bolt at the fore end. The heater *C* is replaced by a hot one when it becomes cooled.

In Fig. 4525, the hollow iron has an opening for the admission of a gas-burner, the flame of which is directed against the bottom of the iron. An elastic tube connects the gas-bracket with the sadiron.

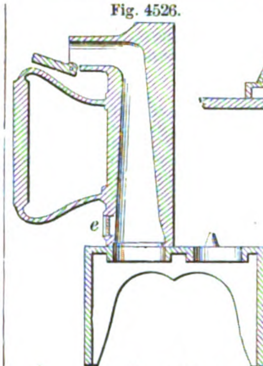
Fig. 4525.



Gas-Jet Sadiron.

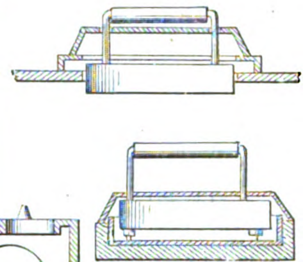
In Fig. 4526, the iron is perforated longitudinally and turned up at the forward end, where it has a lid. The iron is supported on a stand, so that the chimney of a coal-oil lamp may occupy the perforation of the iron. The window *e* allows a view of the flame.

Fig. 4526.



Lamp-Heated Iron.

Fig. 4527.



Sadiron Heaters.

Sad'i-ron Heat'-er. 1. A block to be made red-hot in a fire and placed in a box sadiron.

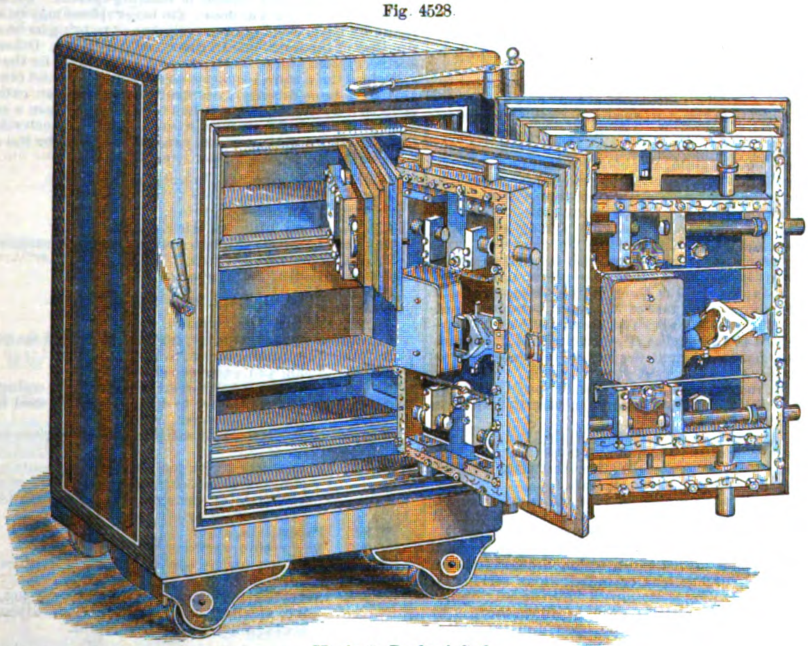
2. A device for heating a sadiron, as a lamp (Fig. 4526) or a gas-jet (Fig. 4525). A stool (Fig. 4527) for holding a flat-iron suspended over the pot-hole of a stove.

3. A heated block (lower part of Fig. 4527) in which an iron is placed to heat.

Sad'wei. (*Glass-making.*) A corruption of *Suint-de-verre* (Fr.). The saline scum or alkaline sulphates formed on glass-pots. Glass-gall. *Sandiver.*

Safe. 1. A strong case for containing money, account-books, and other valuable articles, to guard them from the attacks of burglars, and generally provided with means for protecting them against the action of fire.

Fig. 4528.



Herring's Bankers' Safe.

Safes are of various kinds for different purposes, as, —

Burglar-proof.	Kitchen.	Milk.
Coin.	Marine.	Portable.
Fire-proof.	Match.	Steam fire-proof.
Floating.	Meat.	Water-proof.

Fig. 4528 is an illustration of a modern form of safe, built of wrought-iron, high and low steel welded, and franklinite iron. It has hooped body and solid corners, tongued and grooved door with a lever hinge. The joints are packed with rubber to prevent the operation of the air-pump, — a new and

dangerous resort of burglars in introducing explosives at the cracks, to blow open the doors. The view shows the outer and inner door open, and also the door of the inclosed coin-safe.

The crown jewels of Scotland were, at the time of the Union, in 1707, deposited in an oaken chest. Its lid was secured by three locks, which were forced open in 1818, because the keys could not anywhere be found, leaving us to infer that locksmiths at least were not at that time very expert in the mystery of lock-picking.

Old muniment, deed, and cash chests of this kind were strengthened by iron bands, and generally elaborately carved. They were fastened by several padlocks, or by a multiplicity of bolts shot by a single lock; were formerly considered as secure as first-class safes are at present.

The first examples of metallic safes are coffers, consisting of iron frames, covered with sheet-iron, and strengthened by hoop-iron crossed at right angles on the outside and riveted through. These were common during the last century.

The first English patent for a fire resisting safe was to Richard Scott, in 1801. It consisted of an inner and outer casing of iron or other metal, between which was an interspace on all sides, filled in with charcoal or wood treated with a solution of alkaline salt. The door was made in a similar way.

The next was to William Marr, 1834, who introduced a second metallic lining, so as to form two interspaces within the safe, the inner of which was lined with mica or talc, and filled in with a non-conducting material. These were known as "double-chests," and a variety of non-conducting materials were used for filling, — clay, lime, graphite. Asbestus was used in 1834.

Chubb, 1835, patented a process of rendering woolen safes burglar-proof by lining them with steel or case-hardened iron plates, and fire-proofing iron safes by means of several linings, the interspaces between which were filled with granulated brick, pottery, or other slow conductor of heat.

Milner, 1840, filled the spaces between the linings with an absorbent material, in which were placed vessels containing an alkaline solution or other liquid which could be vaporized by heat, so that in case of fire these would burst and saturate the porous material with vapor.

In 1843. Wilder made a safe of heavy plates of iron, with a filling of hydrated gypsum, hydraulic cement, steatite, alum, and the neutralized and dried residuum of the so-called soda-water manufacture.

Lillie used slabs of chilled cast-iron and flowed cast-iron over wrought-iron ribs. Herring made safes with boiler-iron exterior, hardened steel inner safe, and the interior filled with a casting of franklinite around rods of soft steel.

Tann, 1843, used an outer and an inner metal casing filled in with a composition of equal quantities of alum and gypsum, or Austin's cement; within the inner casing was a wooden lining separated from the casing by a space filled with the same compound.

Sherwood, 1850 to 1854, mentions a safe within a safe, with a filling of fire-brick, melted alum, and clay. Steam or water, or carbonic-acid gas, injected or evolved in the safe. Safe in a safe, intervening space filled with water; corners of angle-iron, and other points of construction. Safe burns loose (in case of fire) and falls into a protected place. An arrangement of a cooling passage around a safe *in situ*.

Newton, 1853, formed a burglar-proof safe consisting of an exterior shell of cast-iron, within which was placed a network of wrought-iron rods; a core was built within these, and fluid iron poured in, filling up that part of the space between it and the shell not occupied by the rods; this became chilled by contact with the surface of the shell. The whole thus formed a compound mass, offering different degrees of resistance, so as to turn aside burglar's tools.

Gulick, 1857. A marine safe, rendered water-proof and having compartments filled with air or cork, so that it may float when thrown overboard.

Chubb, 1857. Inserting plugs of hardened steel into the iron plates of which a safe is made, at short intervals, apart or back of the exterior iron plate, with a corrugated steel plate or strips of steel, so as to prevent drilling into the safe.

Rhodes, 1859. Admitting a flow of cold water to circulate between the inner and outer walls of a safe and its door by a valve which opens when the temperature reaches 212°.

Chatwood, 1860. Backing corrugated or indented iron plates by pouring in fluid metal behind them, which becomes chilled on the face; the hard corrugations or indentations serving to break the drill in case drilling is attempted; also so affixing the lock-chamber that it will partially open to allow the gas to escape if it is attempted to blow the safe open, and then close automatically.

Stocker, 1861. Method of partially converting, piling, and rolling bars and plates for safes, so that their outer surfaces may have the hardness of steel while the inside retains the fibrous nature of iron.

Chatwood, 1862. Mode of making safes from "iron-steel," composed of a plate of steel welded in between two of iron, by forming the top, bottom, and two sides from a single piece, the ends being welded or riveted together; also by casting in one piece of homogeneous or other ductile metal; fire-proofing by lining with wood saturated with solution of sulphate of iron, sulphate of copper, alum, etc., and filling in cavity between the body and lining with non-conducting substance containing vessels filled with sulphurous acid, bisulphide of carbon, or other substance which vaporizes at a low temperature; providing safety-valves and apertures for carrying off the gases in case gunpowder be used, and filling the lock-chamber with an absorbent containing a compound of glycerine and paraffine, or other substance which hinders the powder from exploding.

Price and Dawes, 1863. Backing wrought-iron outer plates, having inward projections, with white cast-iron either joined immediately by pouring or cast separately, and having pieces of hard mineral substance interposed.

Chubb, 1865. Placing the safe door within a recess, and providing it with an exterior bar to prevent its being wedged open.

Thompson, 1865. Recessing the door and providing an interior flange, behind which the bolts shoot to prevent the introduction of wedges.

Varley's, 1865, is the first patent for an electro-magnetic alarm for safes. The signal is given by means of a bell caused to ring when the circuit is broken by moving the safe or opening its door at an improper hour.

Tann, 1865, in order to render safes burglar-proof, welds bars of iron and steel together, hardens them and rivets them on the body of the safe, with or without an interior plate. Also fire-proofing with alum and non-conducting materials.

Hill, 1865, and Hodgson, 1865. Sliding doors of peculiar form to resist the operations of burglars.

Loysel, 1865. A protecting wall, revolving or sliding, is placed between inner and outer cylinders or plates; the inner one contains the door, to which access is had by pushing aside the protecting wall when its bolts are released.

Parrish, Thatcher, and Glasscock, 1865. Forming a series of dovetail projections on the door frame, which fit corresponding mortises in the door to prevent its being forced open by wedges.

Other modifications of this principle, in the form of serrations or undulations in the door and its casing, have since been embraced in various patents. Another method is to form a bead around the door, fitting a groove in the casing. Besides this, various special arrangements have been adopted to prevent the entrance of wedges.

Other methods of combining and arranging metals of different degrees of hardness, so as to break the drill or turn it aside, to render it impossible to drill a continuous hole, have also been contrived.

Billing, 1866. Two hollow spheres, one placed concentrically within the other, and capable of rotating therein. Each is provided with a cylindrical door; the inner sphere may be made to rotate by bevel gearing, or arranged so as to bring its door opposite that of the outer one in the act of unlocking. Other forms, as the ellipsoid and cylinder, may be substituted for the sphere.

Besides the electro-magnetic alarms of Varley and others, signals have been devised to indicate by the sudden extinguishment of a light if an attempt has been made to open a safe.

As filling for safes, we meet with the following materials. The numbers of the United States patents are cited for the convenience of farther reference: —

8,952.	Residuum of soda-water manufacture.
10,661.	Soapstone.
11,842	Tiles, alum, and clay.
12,594.	Alum, pieces of brick, alkali.
28,459.	Alumina, sulphates of alumina, and ammonia.
28,756.	Copperas, gypsum.
39,920.	Starch, water, gypsum.
40,800. 41,521.	Alum in pieces, imbedded in gypsum.
46,228.	Epsom salts, gypsum.
51,937.	Hydraulic cement, sawdust, lime, and sand-mortar.
59,529.	Paper-pulp, alum.
66,790.	Steam and water vessels.
67,154.	Removable water-vessels between the casings.
67,629.	Moistened sponge to dampen powder used for blowing the safe open.
70,390.	Nest of pipes in safe; fusible plug gives way with heat.
76,183.	Vials stopped with fusible alloy and containing sulphuric acid, which reaches carbonate of soda and carbonate of ammonia, generating carbonic-acid gas.
85,893.	Paper-pulp, alum.
87,140.	Raw cotton, sawdust, whiting.
100,632.	Asbestus, earths, such as cement or gypsum, chemical salts, alum.
101,268.	Asbestus, marble-dust, pipe-clay, gypsum, glycerine, mucilage, sulphate magnesia, sulphate soda, borax, alum, sal-soda, paraffine.

Safes and vaults using water or steam for protection in case of fire: —

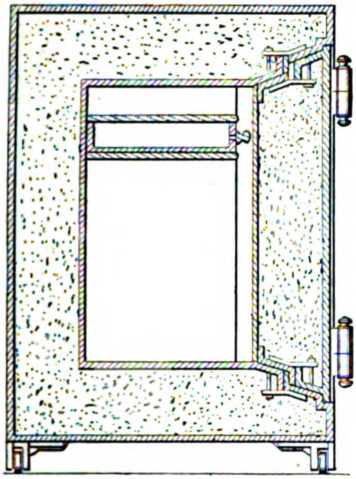
Fig. 4529.

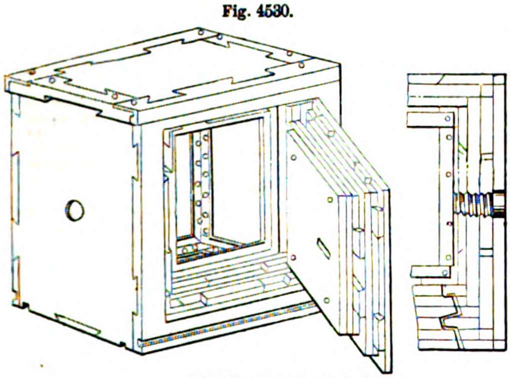


Fire-Proof Safe.

Fig. 4529 shows a safe with exterior and interior walls, with intervening non-conducting filling. The door is also double.

Fig. 4530 is a view of Hall's safe, in which the

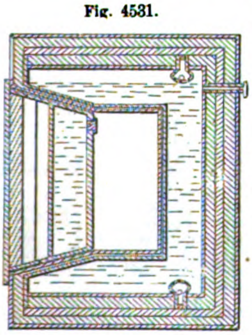
Fig. 4530.



Hall Burglar-Proof Safe.

plates are dovetailed together, and angle-irons are tenoned into the corners to make them mutually sustaining.

Fig. 4531.

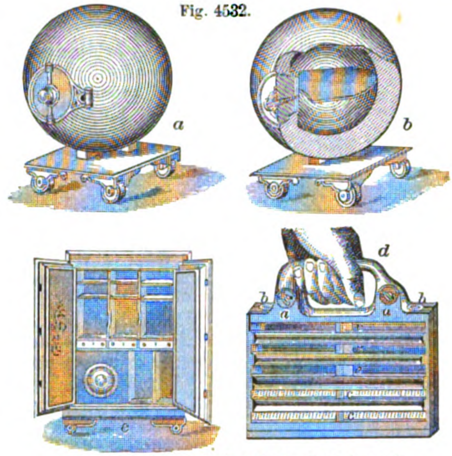


Fire-Proof Safe with Water-Jacket.

Fig. 4531 is a safe having hollow walls connected with the city main.

Marvin's burglar-proof safe (*a b*, Fig. 4532) is of globular form, having no salient points to facilitate the action of a tool for opening it. It is made of chrome-iron, whose extreme hardness renders it impervious to the drill, and the door, which is conical and of cast-steel, is accurately fitted to its opening. It may be simply mounted on a platform with rollers, or fitted within a special compartment of a fire-proof safe, as shown at *c*. The fire-proofing material is a composition of calcined plaster of Paris and alum, which, on being

Fig. 4532.



a b c, Marvin's Spherical Safe; d, Coin-Safe.

heated, gives up its water of crystallization; this is converted into steam, which prevents access of fire to the interior.

The portable coin-safe (*d*, Fig. 4532) is of cast-iron, and opens in the middle like a portmanteau. The two halves are secured together by screws *a a*, and have depressions *b b* to receive seals. The inside has a series of racks *c c*, which may be of different sizes to suit different coins.

2. A ventilated receptacle for meat and other articles.

Safes for meat, etc., have a wooden frame covered with wire gauze or perforated sheet-metal (usually tin-plate), to permit a free circulation of air but prevent the entrance of insects. If the latter material be employed, the perforations are made by a number of dies set in a press and so arranged as to form lines and geometrical figures by turning the sheet on its supporting block or die.

3. (*Saddlery.*) A piece of leather placed under a buckle, to prevent it from chafing.

4. A smooth edge to a file.

Safe-a-larm′. An *alarm-lock*, or other contrivance, to notify a watchman or the police of the tampering with a safe. Alarms for this purpose are usually electro-magnetic, but are also operated by the escape of a body of water or of air confined within the outer shell of the safe.

Safe-edge File. One having a smooth edge, which does not cut a surface against which it impinges.

Safe-guard. 1. (*Railway Engineering.*) *a.* A *rail-guard* at a switch or crossing.

b. A contrivance attached to a locomotive for throwing stones and other obstructions off the track.

2. (*Paper.*) See SAFETY-PAPER.

Safe-lock. A complex lock for a safe. See list under LOCK.

Safe′ty-arch. (*Architecture.*) One placed in a wall to receive a weight of superincumbent masonry and relieve a transom or beam. A *discharging* arch.

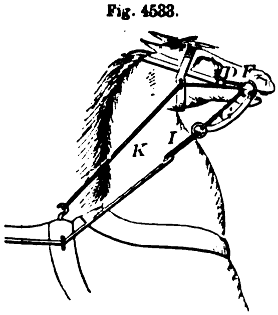
Safe′ty-beam. (*Railway.*) A beam in some forms of railway car-trucks which has straps to catch on in case of breakage. A similar duty is performed

by the safety-stirrups *s v* in Fig. 1159, page 488.

Safe'ty-belt. A belt with cork lining, or made of inflatable material, used to keep a person from sinking beneath the surface of the water. A *life-preserver.*

Safe'ty-bri'dle. (*Saddlery.*) A bridle designed to afford the means of promptly checking horses in the event of their attempting to run away.

Fig. 4533.



Safety-Bridle.

In the example, the bit-ring *F* is suspended on each side from a ring *D* on the cheek-strap by a running-strap *G*, which is connected primarily to the bit-ring, passes up and through the cheek-ring; the running-strap is then carried down through the bit-ring and connected to a safety-rein *I*; the latter is also connected to the gag-rein, so that pulling upon the safety-rein shortens up the gag-rein *K*, and at the same time draws up the bit toward the ring on the cheek-strap. See BRIDLE.

Safe'ty-buoy. A float to be attached to the person to prevent drowning.

Safe'ty-cage. A hoisting and lowering chamber for mines, having guards which arrest the descent if the rope break or overwind. See CAGE; ROPE-ELEVATOR; SAFETY-STOP, etc.

Safe'ty-car. 1. A marine car adapted to be drawn ashore on a hawser connecting a stranded vessel with the land. See LIFE-CAR, Fig. 2927, page 1302.

2. A hoisting cage with stops to arrest its fall if the rope break. See CAGE; SAFETY-STOP.

Safe'ty-chain. (*Railway.*) A slack chain which attaches a truck to a car-body and limits the excursions of the former as it slues round.

Safe'ty-fun'nel. A glass funnel with a long neck for introducing acids, etc., into liquids contained in bottles or retorts, and under a pressure of gas.

Safe'ty-fuse. A water-proof tube, ribbon, or tape containing an inflammable composition for igniting a blasting-cartridge. The composition has a regular rate of burning, say two or three feet in a minute, allowing the miners or quarrymen time to reach a place of safety previous to the explosion. In some cases, however, a much more rapidly burning composition is employed, a much greater length of fuse being used, and fire being communicated at the spot where the men have taken refuge.

Safe'ty-guard. (*Railway Engineering.*) An axle-guard to keep the car-wheels on a track at a switch.

Fig. 4534.

Safety-Hook.

Safe'ty-hoist. 1. A hoisting-gear on the differential-pulley principle, which will not allow the load to descend by the run. See SACK-HOIST.

2. A catch to prevent the fall of a cage when a rope breaks. See Fig. 4539.

Safe'ty-hook. A device to prevent a watch from being detached from its chain by accident or by a sudden jerk. In the figure, this is effected by screwing down the nut *d* against the shoulder *o*; this prevents the tongue *i* from turning open on its pivot.

Safe'ty-lamp. A lamp surrounded by a cylinder of wire gauze, invented about 1815 by Sir Humphry Davy, to obviate the danger of fire-damp explosions in mines. A similar contrivance was, about the same time, invented by the elder Stephenson.

Davy, after numerous experiments upon the passage of flame through narrow apertures, found that wire gauze of sufficient fineness acted as a complete barrier to its transmission, and that the gas in question could not be exploded unless absolutely in contact with the flame.

The principle may be readily demonstrated by holding a sheet of wire gauze above a flame and bringing it down gradually till it divides the cone of inflammable vapor and matter by a horizontal section. That which is below the gauze will continue to burn, but that above may be blown out and relit; but the flame will not communicate through the gauze to the vapors above.

Sir Humphry Davy gave some offense to the faculty, who could not keep up with his discoveries, and especially a patriarch in Aberdeen, who ignored Davy's researches for some years. The discovery of potassium was so palpable a hit that the sage had to relax the quarantine, and announced: "Gentlemen, both potash and soda are now said to be metallic oxides; the oxides, in fact, of two metals, called potassium and sodium by the discoverer of them, — one Davy, in London, — *a verra troublesome person in chymistry.*"

Davy's lamp (*a*), sent to the mines for experimental use, has 748 apertures to the square inch, the wire being $\frac{1}{70}$ of an inch in diameter. The cage or cylinder has double joinings, the gauze being lapped over at that point. The parts are fastened by hard solder. The limit of size is 2 inches in diameter; that of the meshes $\frac{1}{20}$ of an inch. The number of meshes was subsequently increased by Dr. Clanny, who also made other improvements in the lamp, to 1,296 per square inch.

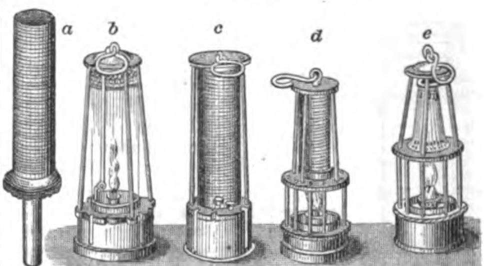
In Mueseler's safety-lamp, Belgian, a part of the metallic covering which surrounds the flame and forms the chimney is replaced by glass, affording more light than that yielded by the Davy lamp. The air for supporting combustion is admitted from above through two wire gauze diaphragms at right angles to each other.

Eloin's lamp, also Belgian, has a concave glass at its lower part, to disperse the rays of light.

Messrs. Liaute and Denoyel, students in L'Ecole Polytechnique, of Paris, have devised a lamp in which the gas necessary to support combustion is generated in the lamp itself. In an experiment made at Paris, one of the lamps was burned for three quarters of an hour eight feet under water, and when drawn up was burning as brightly as at first.

a represents the first Davy safety lamp, in which a wire cylinder was placed as casing over the flame. It is now in the possession of the Royal Society.

Fig. 4535.



Safety-Lamps.

b, English lamp. The light inclosed in a glass cylinder, the upper end of which is protected by wire gauze.

c. English lamp. The gauze cylinder protected

d, French lamp, Mueseler's. Glass and gauze cylinders.
e, petroleum lamp. Glass and gauze.
See also PHOTO-ELECTRIC LAMP.

Safe'ty-lock. 1. (*Lock.*) A lock so contrived as not to be opened by a picklock or without the proper key. See LOCK.

2. (*Fire-arms.*) One provided with a stop or catch to prevent accidental discharge.

Safe'ty-pa'per. A paper chemically or mechanically prepared, so that its color or texture will be changed by being tampered with; or a paper so difficult of production as to give an additional measure of safety.

Of safety-papers there are several kinds: —

1. Paper made with distinguishing marks to indicate proprietorship, as with the Bank of England water-mark, to imitate which is felony. Or the paper of the United States currency, which has silk fibers united with the pulp, the imitation of which is felony.

2. Paper made with layers or materials which are disturbed by erasure or chemical discharge of written or printed contents, so as to prevent fraudulent tampering.

3. Paper made of peculiar materials or color, to prevent copying by photographic means.

A number of processes may be cited: —

One kind is made of a pulp tinged with a stain easily affected by chlorine, acids, or alkalies, and is made into sheets as usual.

Water-marks made by wires twined among the meshes of the wire cloth on which the paper is made. See WATER-MARK.

Threads embodied in the web of the paper. Colored threads systematically arranged were formerly used in England for post-office envelopes and exchequer bills.

Silken fibers mixed with the pulp or dusted upon it in process of formation; as used in the United States paper currency.

Tigere, 1817. Treating the pulp or the paper, previous to sizing, with solution of prussiate of potash.

Sir Wm. Congreve, 1819. A colored layer of pulp in combination with white layers.

Printing upon one sheet and covering with an outer layer plain or water-marked.

Glynn and Appel, 1821. Mixing a copper salt in the pulp and afterward adding an alkali or alkaline salt to produce a copious precipitate. The pulp is then washed, made into paper and dipped in a saponaceous compound.

Stevenson, 1837. Incorporating into paper a metallic base, as manganese, and a neutral compound, as prussiate of potash, to protect writing from being tampered with.

Varnham, 1845. A paper consisting of a white sheet or surface on one or both sides of a colored sheet.

Stones, 1851. An iodide or bromide in connection with ferrocyanide of potassium and starch are combined with the pulp.

Johnson, 1853. Employing the rough and irregular surface produced by the fracture of cast-iron or other brittle metal to form a water-mark for paper by taking an impression therefrom on soft metal, gutta-percha, etc., and afterward transferring it to the wire cloth on which the paper is made.

Scoutteten, 1853. Treating paper with caoutchouc dissolved in bisulphide of carbon, to render it impermeable and to prevent erasures or chemical action.

Ross, 1854. Water-lining or printing the denomination of the note in colors while the pulp is yet soft.

Evans, 1854. Embodying a lace or open-work fabric in the pulp when making.

Courboulay, 1856. Mixing in the pulp, or applying to the paper salts of iodine or bromine.

Loubatieres, 1857. Manufacturing paper in layers, any or all of which might be colored, or have impressions or conspicuous marks for preventing forgery.

Herapath, 1858. Imbuing paper during or after its manufacture with a solution of a ferrocyanide, a ferrid-cyanide, or sulpho-cyanide of potassium, sodium, or ammonium.

Seyd and Brewer, 1858. Applying aqueous solution of ferrocyanide of potassium or other salt, which forms an indelible compound with the ferruginous base of writing-ink.

Sparre, 1859. Opaque matter, such as Prussian blue, white or red lead, insoluble in water, is stenciled on one layer of the paper web, forming a regular pattern; this is then covered by a second layer of paper.

Moss, 1859. Coloring-matter prepared from burned china or other clay, oxide of chromium or sulphur, is combined with the pulp.

Barclay, 1859. Incorporating with the paper, 1, soluble ferrocyanides, ferrid-cyanides, and sulpho-cyanides of various metals, or forming dibasic salts with potassium, sodium, or ammonium, in conjunction with vegetable, animal, or metallic coloring-matters.

2. Salts of manganese, lead, or nickel not containing ferrocyanogen.

3. Ferrocyanides, etc., of potassium, sodium, and ammonium, in conjunction with insoluble salts of manganese, lead, or nickel.

4. Insoluble ferro- or ferrid-cyanide of manganese, or soluble sulpho-cyanide of manganese alone, or forming double salts with potassium, sodium, or ammonium.

Hooper, 1860. Oxides of iron, either alone or dissolved in an acid, are mixed with the pulp.

Nissen, 1860. Treating paper with a preparation of iron, together with ammonia, prussiate of potash and chlorine, while in the pulp or being sized.

Middleton, 1860. One portion of a bank-note is printed upon one sheet of thin paper and the other part on another; the two are then cemented together by india-rubber, gutta-percha, or other compound. The interior printing is seen through its covering sheet, so that the whole device on the note appears on its face.

Olier, 1861. Several layers of paper of various materials and colors are employed; the middle one may be colored with a deleble dye, whose color will be changed by the application of chemicals to the outer layer.

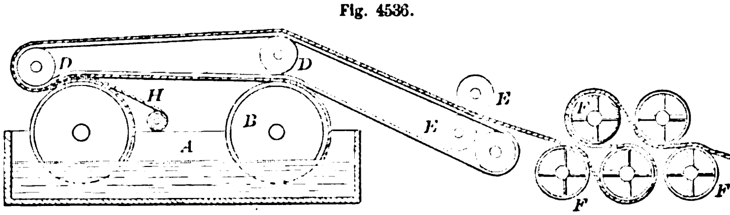
Olier, 1863. A paper of three layers of different thicknesses, the central one having an easily removable color, and the external layers charged with silicate of magnesia or other salt.

Forster and Draper, 1864. Treating paper during or after its manufacture with artificial ultramarine and Prussian blue or other metallic compound.

Besides these, are numerous devices for preventing copying by photographic means, certain colors being employed in parts of the genuine note which are not capable of giving a photographic image with the distinctness required.

In a paper made by the apparatus shown in Fig. 4536, threads of rubber or gutta-percha from the roll *H* are inserted between the two layers of the double web, formed by the making cylinders *B D D*, compacted by the press-rolls *E E*, and softened and united to the paper fiber on passing through the heated drying-cylinders *F F*.

Fig. 4536.



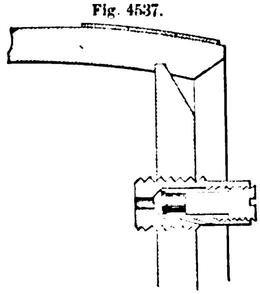
Safety-Paper Machine.

Safe'ty-plug. 1. (*Steam-boiler.*) A bolt having the center filled with a fusible metal and screwed into the top of the fire-box, so that the metal may melt out when the temperature of the inside of the boiler reaches a certain limit.

2. A device to prevent barrels from bursting by the expansion of their contents, or gases generated therein.

It consists of a hollow metallic screw-plug, having a valve, which is supported against its seat by an adjustable spring of india-rubber, or other elastic material, which will yield when the pressure in the vessel from any cause exceeds a certain limit.

Fig. 4537.



Safety-Plug for Barrels.

Safe'ty-rail. (*Railway Engineering.*) A guard-

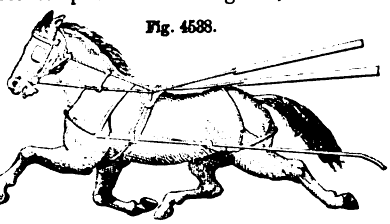
rail at a switch to bear against the inside edge of a wheel-flange to keep the tread on the *track*-rail.

Safe'ty-ra'zor. A razor having guards at each side of the edge to prevent nervous and infirm persons from accidentally cutting themselves in shaving. See RAZOR.

Safe'ty-rein. (*Saddlery.*) A rein to be used in case the horse attempts to run away. It usually has a special purchase of some kind intended to draw the bit violently into the angles of the mouth; to throw a blind over the eyes; to draw a choking-strap around the throat, etc., etc.

In the example, the gag-rein passes through a loop above the bit-ring, and is connected to the cheek-piece by the brow band. It is also connected by cross strap to the driving-rein, which has a

Fig. 4538.

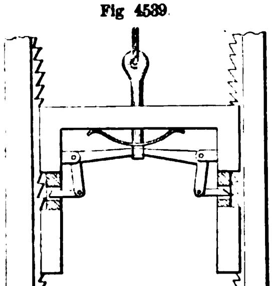


Safety-Rein.

spring section next the bit. The driving and gag-reins exert their usual functions until the horse is restive, when severe draft on the driving-rein stretches the elastic section and transfers the power to the gag, which draws the bit into the angle of the mouth.

Safe'ty-stop. (*Hoisting-machine.*) Provision is made in hoisting-machines which are hoisted by a rope for being automatically stopped when the rope breaks.

Fig 4539.

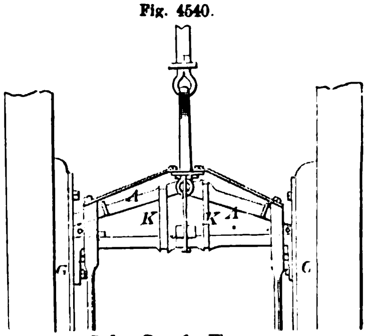


Safety-Stop.

Otis's apparatus for this purpose (Fig. 4539) consists of a pair of pawls which engage ratchet teeth in the bars attached to the uprights on the side of the shaft. The pawls are held out of engagement with the racks so long as the weight of the platform is suspended from the rope, but if the rope break the spring comes into action and depresses the elbow levers, which force out the pawls and prevent the farther descent of the platform. See ROPE-ELEVATOR.

In Fig. 4540, the rubber springs *K K*, in case the rope breaks, draw down the inner ends of the arms *A A*, forcing their beveled outer ends into a rack on the guides *G G*.

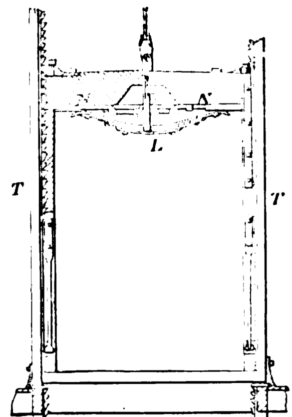
Fig. 4540.



Safety-Stop for Elevators.

In Fig 4541, the pressure of the elliptic spring *L* against the levers *N N* is relieved sufficiently to allow them to clear the notches in the guides *T T* so long as the hoisting-rope is kept tense by the weight of the cage; but in case of breakage the spring acts to force out two sliding catch-bolts into the notches, preventing farther descent.

Fig. 4541.



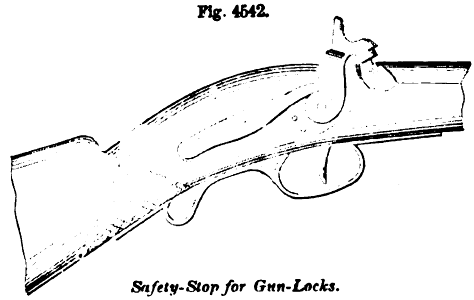
Miller's Safety-Stop.

2. (*Fire-arms.*) A device to prevent the accidental discharge of a gun. In Fig. 4542, a flat spring catches against the rear of the hammer and locks it against the nipple; when the spring is pressed against the stock, the hammer is free to be cocked.

3. A device on a pulley or sheave, to keep it from running backward.

4. A stop-motion in a spinning-machine, knitting-machine, loom, etc., which arrests the motion in

Fig. 4542.



Safety-Stop for Gun-Locks.

case of the breakage of a sliver, yarn, or thread, as the case may be.

Safe'ty-strap. (*Saddlery.*) An extra back band passing over the seat of a gig-saddle, having holes through which the terrets pass to keep it in position, the ends being buckled to the shaft-tug; used as a safeguard on light trotting harness.

Safe'ty-switch. (*Railway.*) A switch which returns automatically to its normal position after having been moved to let a train on to or off of a siding.

Safe'ty-tube. A tube used in chemical operations to prevent the bursting of a vessel from the sudden disengagement of gases, accession of air, or the mingling of fluids in vessels connected together.

Safe'ty-valve. (*Steam-engine.*) A valve which automatically opens to permit steam to escape or air to enter the boiler in order to prevent its explosion or collapse.

Internal. Opens to the inner side when the pressure of steam is less than a given weight.

External. Opens to the outside when the pressure of steam is greater than a given weight.

The latter is more important, and is an indispensable attachment to every boiler. It consists commonly of a lever of the third class pivoted at one end; the valve, which is on a stem projecting from the lower side of the lever, is conical, and fits into a corresponding seat. The lever has notches for receiving the hook or loop of a weight which is suspended

therefrom, and may be moved from one notch to another, like the weight of a steelyard, so that a greater or less amount of steam pressure may be required to lift the valve from its seat.

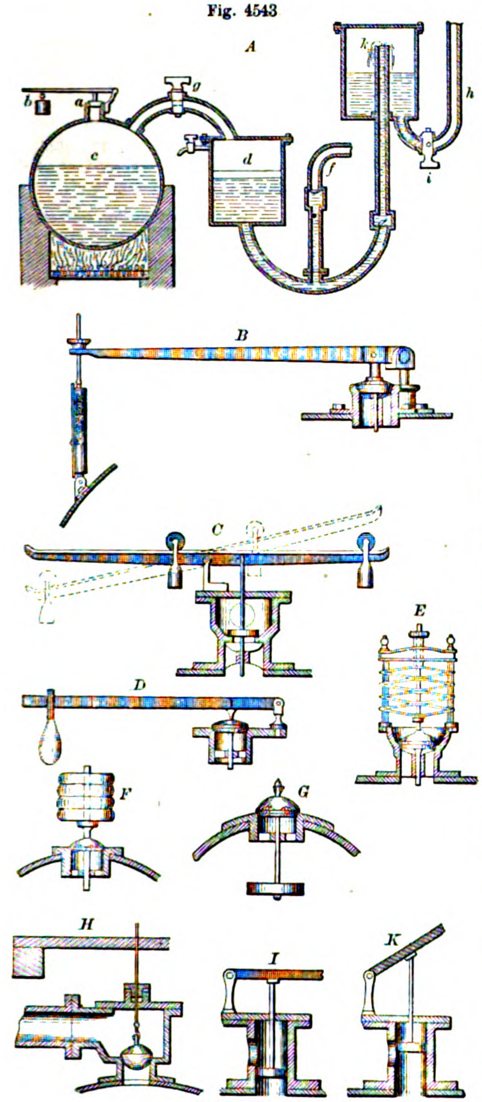
The safety-valve is also used with boilers of various kinds, air and gas engines, proving-pumps, hydraulic-presses.

Locomotive-engines have two valves placed on the boiler for the escape of steam when it exceeds certain limits. One of them is placed beyond the control of the engineer, and is called the lock-up valve. The other is regulated by a lever and spring-balance at a little lower pressure than the lock-up valve.

It was invented by Papin, 1695, and was originally applied to his *digester*.

A, Fig. 4543, shows Papin's safety-valve in connection with his engine for raising water. *a* is the valve, which is a conical stopper, representing the power in a lever of the third kind, weighted at *b*, lifted by the valve when the steam pressure in the boiler *c* exceeds a fixed limit. For raising water by this machine, a vacuum was produced over the float *d* in the chamber *e*, causing the water to rise through the induction-pipe *f* and fill the chamber; on turning the cock *g*, steam was admitted above the float, forcing the water out through the discharge-pipe *h*, the cock *i* being opened for that purpose. An air-chamber *k* made the discharge continuous.

Fig. 4543



Safety-Valves.

B, safety-valve for high-pressure boilers. The weight is replaced by a spiral spring whose tension is adjusted by a thumb-nut.

C, French safety-valve. The lever has two equal arms, having weights traversing on rollers; when the pressure reaches the fixed limit, the weights roll down the tilted lever, leaving the valve opening free until they are replaced.

D, common safety-valve with graduated lever, on which the weight may be set at any required number of pounds' pressure.

E, the valve is held to its seat by bent springs.

F, a series of removable perforated weights on the valve-spindle are employed.

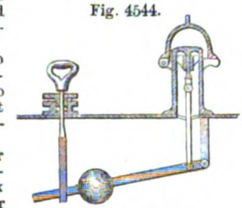
G, the weight is attached to a stem projecting downwardly into the boiler.

H, Nimmo's valve for steamboat boilers; a modification of the above.

I, *K*, valve used by Mr. Southern in his experiments on high-pressure steam; the first in closed, the second in open position.

In the conditions of competition for the £500 prize for the best locomotive-engine, offered by the Liverpool and Manchester Railway Company, and won by Stephenson's "Rocket," it was stated that one of the safety-valves should be "locked up." See also LOCK-UP SAFETY-VALVE.

Fig. 4544.



Lock-up Safety-Valve.

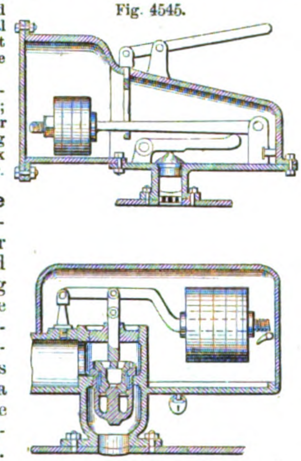
A British form of the lock-up safety-valve, which is inaccessible to the engineer, except to lift it to ascertain that it is not set fast, is shown in the illustration (Fig. 4544).

Fig. 4545 shows two other forms of safety-valves for steam-boilers; one from Burch's work on "Steam-Boilers"; the lower one is Cameron's valve.

In Fig. 4546, the lever and weight are toothed on their under surfaces, engaging the teeth of a spur-wheel, to whose axis an index is attached which indicates on a dial the steam pressure at which the safety-valve is set.

Fig. 4547 is a safety-valve, or blow-off valve; operated in the latter case by a stem passing through a stuffing-box in the front of the boiler.

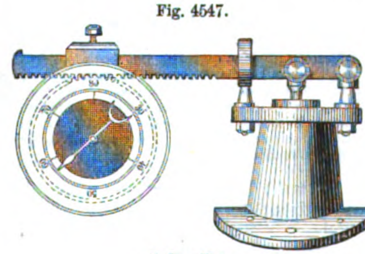
Fig. 4545.



Safety-Valves.

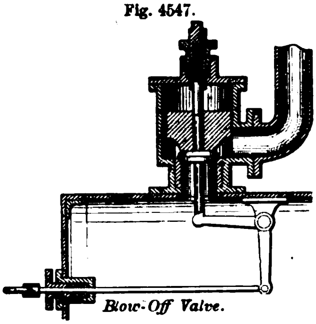
Safe′ty-valve Le′ver. (*Steam-engine.*) The lever to which is attached the weight or spring that controls the opening of the safety-valve. In locomotive-engines, it is fixed at one end to a stud and rests on the valve at a short distance from this stud. Its length is proportioned to the area of the valve, and a spring-balance indicates the pressure

Fig. 4547.



Safety-Valve.

Fig. 4547.



Blow-Off Valve.

in pounds per square inch on the boiler above atmospheric pressure.

Saf'fi-an. (*Leather.*) A dyed leather made at Astracan and other parts of Asiatic Russia. The skins of bucks and goats are used for the purpose, and the colors used are red and yellow. The articles used in its preparation are lime, dog's dung, and bran. Honey is used after the bran. After three days' fermentation, the skin is salted and dried. The skin is then dyed, and tanned with sumach. The red color is given by cochineal and *ericoides*, an alkaline plant growing plentifully on the Tartarian salt deserts. The color is finished with alum. For the finest qualities, sorrel is added in the cochineal bath, and the tanning is done by galls. The roughness is given by a heavy iron rake with blunt points.

Sag. 1. The bending downward of the middle of a beam or other object supported at both ends. Sometimes beams are framed with a slight *camber*, which neutralizes the *sag*.

Hogging is the depression of the ends when supported in the middle. See HOG-FRAME.

2. The movement of a ship when making considerable *lee-way*. It is the opposite of *holding* a good wind, or bearing up well to *windward*.

Sag'a-thy. (*Fabric.*) A mixed fabric of silk and cotton.

Sag'ger. (*Porcelain.*) Saggers for earthenware hold a pile of ware in the *biscuit* or *white* condition, but china and fine porcelain articles are contained separately in small *saggers* called *setters*, which are of a shape to suit the article. They are *reared* in *bungs* in the *kiln* where they are *fired*. *Saggar; seggar.* See SEGGAR.

Clay for making pots to be used as *saggers*.

Sag'ging. (*Nautical.*) A term the reverse of *hogging*. Applied to a ship when the middle portion of the keel and bottom arch downward.

Sa-git'ta. (*Masonry.*) *a.* The keystone of an arch.

b. The versed sine of an arch; from the resemblance of an arrow standing upright on the string of a bow.

Sa'go-mak'ing. Sago is a variety of starch prepared from the pith of palms belonging to the genus *sagus*, and employed in various culinary preparations, particularly for invalids.

At the proper age, the sago-palm is cut down, the wood being a mere shell around a most abundant pith. A strip of the bark and shell of the trunk is removed, and the interior pulp beaten up with stone hammers until only a trough about half an inch thick is left. The pulp is then taken in baskets made of sago-palm leaves, and washed in troughs made from the trunks of the tree, strained through sieves made from the fiber and allowed to settle, this part of the process resembling the manufacture of starch. When a sufficient quantity has been obtained, it is made into thirty-pound rolls, wrapped in sago leaves, and is ready for market under the name of raw sago. By the Malays this farina is broken up into powder and dried in the sun. This is baked in shapes in an oven. The cakes are dried in the sun, tied in bundles, and packed away. They are eaten dry, wet, toasted, or boiled like rice.

Sa'ic. (*Vessel.*) A Levantine vessel like a ketch, but without top-gallantsail or mizzen-topsail.

Sail. A canvas cloth spread to catch the wind.

1. (*Nautical.*) It is supported by the masts, spars, or stays of a vessel.

2. The propelling sheet of a wind-driven carriage.

3. The clothing on the radial arms of a windmill.

4. A funnel-shaped bag on the deck of a vessel to intercept or gather air and lead it below deck for the purpose of ventilation. A *wind-sail*.

The Greek tradition that Dædalus, the Athenian, 1240 B. C., first contrived sails, is disproved by the expeditions of the Phœnicians around the Mediterranean previous to that time, by the fact that the Nile had been for over 1,000 years the great highway of Egypt, and the rivers of China for an equal or greater period had run through a well-peopled country.

"Sails come from Egypt, and this paper too."
HERMIPPUS; quoted by ATHENÆUS, A. D. 220.

The Veneti, a tribe of the Belgæ, had leathern sails managed by chains. The Romans tore them by scythes on the ends of long poles. — STRABO.

Sails take their names from the mast, yard, or stay on which they are stretched. Some of the names indicate relative elevation: —

Mainsail.	Foretopmast-staysail.
Foretopsail.	Maintopmast-studdingsail.
Mizzen-royal-sail.	Main-skysail, etc., etc.
Main-staysail.	See Fig. 4549.

They also differ in their mode of extension: —

A *square sail* is extended by a *yard* or *boom* (see Fig. 4548).
A *fore-and-aft* sail is extended by a *gaff*, *stay*, *sprit*, or *yard*.

Names indicative of form: —

Square sail.	Shoulder-of-mutton sail, etc.
Lateen-sail.	

Specific names of various derivations: —

Bonnet.	Driver.
Jib.	Lug.
Ring-tail.	Save-all.
Skysail.	Spanker.
Spencer.	Trysail.

Names derived from normal position: —

Fore-and-aft sail.	Studdingsail.
Water-sail.	Bonnet.

By position before or abaft the *center of effort* of the vessel: —

Head-sail.	After-sail.

The *square* sails are: *courses*, *topsails*, *top-gallantsails*, *royals*, and *skysails*, on each mast. *Lug* and *studding* sails are also enumerated among the *square* sails.

The *fore-and-aft* sails are: *staysails*, *trysails*, *jibs*, *drivers*, *spankers*, *gaff-topsails*; and in sloops, cutters, and schooners, the main and fore sails, and frequently the topsails.

Trysails are bent to small spars abaft the lower masts. That of the mizzen is called the *spanker*.

Staysails are those hoisted on the *stays* of the masts. The *foretopmast-staysail*, *jib*, *flying-jib*, and *jib-of-jib* are of this kind. Some jibs do not run on a stay. See CUTTER.

The *courses* are the sails sustained by the lower masts, as the *foresail*, *mainsail*, and *spanker*.

The parts and accessories of a sail are: —

Head; the upper edge.

Foot; the lower edge.

Leech; the vertical edge. The *weather-leech* is the *luff*. The *lee-leech* is the *after*-leech.

Clew; one of the lower corners of a square sail; the lower after-corner of a fore-and-aft sail.

Tack; the lower weather-corner of a square sail; the lower forward corner of a fore-and-aft sail.

Bunt; the middle part of a sail, vertically.

Bolt-rope; sewed round the edges of a sail; it is called the *head*, *foot*, or *leech rope*, according to position.

Earing; the upper corner of a square sail.

The *depth* of a sail is from the *head-rope* to the *foot-rope* of a square sail; the length of the after-leech of a fore-and-aft sail.

Tabling; an additional thickness of canvas on the *roped* side of a sail.

Reef-band; a strengthening band across the sail at the eyelet-holes for the *reef-points*.

Reef-points; tapering pieces of braided cordage called *sennit*, which pass through the eyelets and hang down an equal distance before and abaft the sail. The length is such as to enable them to reach twice round the yard.

Reef-line; a substitute for *reef-points*, consisting of a rope rove through the eyelets of a reef-band and over the yard.

Reef-tackle; a purchase by which the *reef-cringles* on the leech of the sail are hauled up to the yard in reefing.

Belly-band; a strengthening band of canvas running horizontally midway between the lowest reef-band and the foot of the sail.

Buntline-cloths; bands of canvas running up and down from the belly-band to the foot of the sail.

Reef-tackle patch; a strengthening piece of canvas at the reef-cringle on the leech of a sail.

Top-lining; a patch on the lower part of a topsail where it chafes on the *top* of a lower mast.

Cringle; a loop on the leech of a sail to which the reef-tackles are attached. The head-cringle is a loop on the upper corner of a sail by which it is lashed to the *head-earing strops* on the yard-arms.

The *head-rope* of the sail is secured to the *jackstay* on the yard by *robands* passing through eyelet-holes.

The *roach* of the sail is the concave curve of the foot.

A *save-all* is a piece which fills up the *roach* when required.

For the ropes to operate yards, sails, etc., see RUNNING-RIGGING.

A sail is —

Bent; that is, fastened to its yard or other spar; or

Unbent; cast loose therefrom.

Furled; drawn up to the yard or spar and secured by gaskets.

Reefed; reduced in area by tying up a portion of the *foot* or of the *head*, as the case may be.

Atrip; hoisted and sheeted home ready for trimming.

Trimmed; when the yards are braced up in the most advantageous position to catch the wind.

To *set* sail; to expand it on its yard or stay.

To *make* sail is to spread all or a part of the sails or shake out the reefs.

To *shorten* sail is to furl, reef, or clew a part of the sails.

To *strike* sail is to lower it suddenly by letting run the halyards.

To *loosen* sail; to shake it from the yard to dry.

To *back* sail: to handle the sail so as to catch the wind in a direction to force the ship astern.

To *hand* sail is to *furl* it.

To *brace* a sail is to move it by bracing the yards; to *brace about* is to brace them in a contrary direction; to *brace in* is to haul in the weather-braces; to *brace up* is to haul in the lee-braces.

To *brail* is to haul up the foot and leeches of a sail by its brails.

To *fill* is to brace the yards so that the wind will act upon the after surface of the sails.

To *settle down* a sail is to lower it to the cap handsomely.

Square sails are worked by the motions of the yards which are effected by those parts of the running-rigging known as

Halyards.	Lifts.
Braces.	

The ropes especially devoted to the sails are the

Sheets.	Buntlines.
Jacks.	Downhauls.
Clewlines.	Brails.
Bowlines.	Outhaulers.

Canvas or sail-cloth is made in grades of quality and strength. Of the latter it is Nos. 1 to 8. The first number is the strongest, and is used for storm-sails; No. 8 for small sails and studdingsails.

The seams of the cloth in a square sail are vertical. In a fore-and-aft sail they are parallel with the after-*leach*.

In Cowan's patent (English) the seams are horizontal.

The seams have also been made diagonal, with no improved effect, but rather otherwise.

Some of the terms employed by sail-makers are, —

Seaming; sewing the breadths together.

Goring; cutting out the wedge-shaped pieces where the sail narrows.

Tabling; putting on the strengthening strips around the edge, where the cringles are inserted

Sewing on the *reef*, *belly*, *lining*, and *buntline bands*.

Roping; sewing on the *bolt-rope*.

Marling on the clews and foot-rope.

Many attempts have been made to avoid the necessity of going aloft to set or furl sails, which is a dangerous duty, especially in stormy and wintry weather.

Cunningham's patent (English) is for a yard, rotated by ropes from the deck, so as to wind on or unwind the sail in furling or setting. The plan involves a vertical division of the sail, and has not been generally adopted.

Fig. 4548 is a *course* or lower square-sail.

a, yard.
b, head-rope.
c, foot-rope.

Frigate under Full Sail.

a, spanker.	*m*, foresail.
b, mizzen-topsail.	*n*, fore-studdingsail.
c, mizzen-top-gallantsail.	*o*, foretopsail.
d, mizzen-royal.	*p*, foretopmast-studdingsail.
e, mainsail.	*q*, fore-top-gallantsail
f, main-topsail.	*r*, fore-top-gallant-studding-sail.
g, maintopmast-studdingsail.	*s*, fore-royal.
h, main-top-gallantsail.	*t*, fore-royal-studdingsail.
i i, main-top-gallant-studding-sails.	*u*, jib.
k, main-royal.	*v*, flying-jib.
l l, main-royal-studdingsails.	

Sail-cloth. (*Fabric.*) A canvas for sails, made of flax, hemp, cotton, or jute. In thickness, and consequent weight, it varies from 22 to 44 pounds per bolt of 38 yards, 24 inches wide.

Sail-clutch. An iron band fastening a sail; a substitute for hoops or lashing.

Sail-hook. (*Nautical.*) A small hook for holding the sail-cloth while sewing.

Sail-hoop. (*Nautical.*) The wooden rings by which fore-and-aft sails are secured to masts and stays.

Sail′ing-car′riage. A wheeled vehicle propelled by sails. Such appear to have been used by the Chinese, and at the present day a kind of sled provided with sails is sometimes met with on our northern rivers. They are capable of great speed. See ICE-BOAT; KITE.

Sail-loft. A large apartment where sails are cut out and made.

Sail-nee′dle. (*Nautical.*) A large needle with triangular tapering end, used in sewing canvas.

Sail-room. (*Nautical.*) An apartment or bunk on board ship where spare sails are stowed.

Sail-wheel. A name sometimes applied to the tachometer of Woltmann. See TACHOMETER.

Sa′ker. (*Ordnance.*) An old form of cannon, 8 or 9 feet long, and of 5 pounds' caliber.

> "The cannon, blunderbuss, and saker,
> He was the inventor of and maker."
>
> HUDIBRAS.

Sal′a-man′der. 1. A circular iron plate used in cooking. A *griddle*.

2. A term sometimes applied to a fire-proof safe.

3. A heated iron for firing cannon, called on shipboard a loggerhead. Not now in use.

Sal'a-man'der's Hair. Asbestus, amianthus, mineral flax. See pages 167, 168.

Sa'li-ent An'gle. (*Fortification.*) Two united faces, presenting the vertex outward, as in the *redan* and *bastion*. See Fig. 4218.

Sal'i-nom'e-ter. An instrument for ascertaining the saltness of water.

The *thermometrical* method is by ascertaining the boiling-point of the brine. This is used in salt-works, the scale being graduated to indicate percentages.

The *hydrometric* method is by finding its specific gravity at a given temperature.

The following table shows the boiling-points and specific gravities of sea-water (at 60° Fah.) of different degrees of saturation, expressed in parts of salt contained therein, the barometer indicating 30 inches of mercury: —

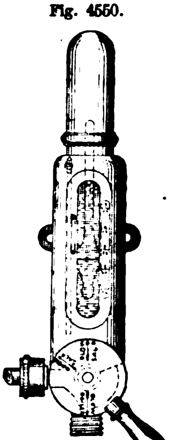
	Saltness.	Boils.	Sp. Gr.
Pure water.......	0	212°	1.
Common sea-water	$\frac{1}{32}$	213 2°	1.029
	$\frac{2}{32}$	214.4°	1 058
	$\frac{3}{32}$	215.5°	1.087
Up to this point no deposit will be formed.			
	$\frac{4}{32}$	216.7°	1.116
	$\frac{5}{32}$	217.9°	1.145
	$\frac{6}{32}$	219.1°	1.174
	$\frac{7}{32}$	220.3°	1.203
	$\frac{8}{32}$	221 5°	1.232
	$\frac{9}{32}$	222.7°	1 261
	$\frac{10}{32}$	223.8°	1.290
	$\frac{11}{32}$	225.0°	1.319
	$\frac{12}{32}$	226.1°	1.348 saturated solution.

As a general rule, the boiling-point of the water, when subjected to a pressure of one atmosphere, should never be allowed to exceed 216°. The temperature must be ascertained by drawing off a small quantity of the brine, and boiling it in a deep copper vessel in the engine-room, a correction being made, if necessary, for the state of the barometer.

The following table shows the hight of the boiling-point in Fahrenheit's scale at different hights of the barometer: —

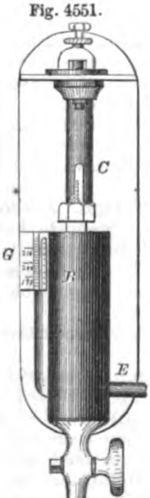
Barometer.	Boiling-point.	Barometer.	Boiling-point.
27 inches.	206.96°	29½ inches.	211 20°
27½ inches.	207.84°	30 inches.	212°
28 inches.	208.69°	30½ inches.	212.79°
28½ inches.	209 55°	31 inches.	213.57°
29 inches.	210.38°		

Fig. 4550.



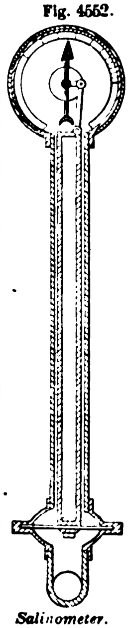
Salinometer.

Fig. 4551.



Salinometer.

Fig. 4552.



Salinometer.

An ordinary form of marine salinometer is a graduated glass tube, whose bottom swells into two bulbs, the lower the smaller, and containing shot, to cause the instrument to float vertically. The greater the degree of saturation, the heavier the liquid, and the consequent hight of the graduated stem relatively to the water's surface.

The water-chamber of Gamble's salinometer (Fig. 4550) is connected to the boiler, so as to give a constant indication of the degree of saturation, and contains a thermometer for showing the temperature of the water in the boiler. The case has a glass face, through which the salinometer can be seen, and the bulb has a horizontal line, whose coincidence with one of the graduations at the side of the case shows the proportion of salt contained in the water, as $\frac{1}{32}$, $\frac{2}{32}$, etc.; intermediate proportions may be estimated by the eye.

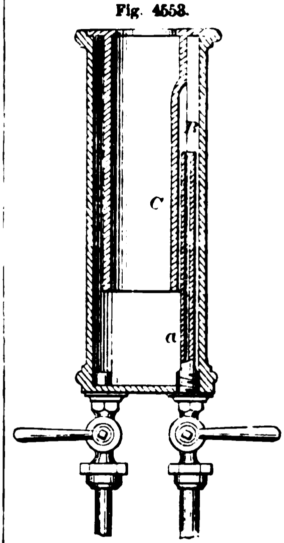
In Fig. 4551, water from the boiler is drawn through the pipe *E* into the cylinder *B*. The upper end of the hydrometer is visible through an opening in the tube *C*, so as to expose the graduations. A thermometer *G* indicates the boiling-point.

In Fig. 4552, an inner tube is weighted to balance a column of water of known hight and density, and rests upon a flexible diaphragm, through which the pressure of the water is transmitted. Variations of pressure are indicated by an index connected with the upper end of the tube and traversing the dial.

Sal'i-nom'e-ter-pot. A vessel into which water from the boiler is drawn, in order to be tested by the salinometer.

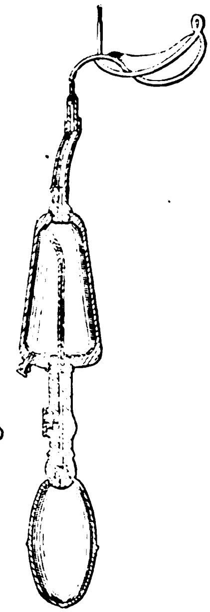
In Sewell's, the water entering at the induction-pipe *a* is received in the outer chamber *B*, and thence passes downward and around the lower edge of the inner chamber *C*, so as to prevent a scalding jet flying out at the top.

Fig. 4553.



Salinometer-Pot.

Fig. 4554.



Saliva-Pump.

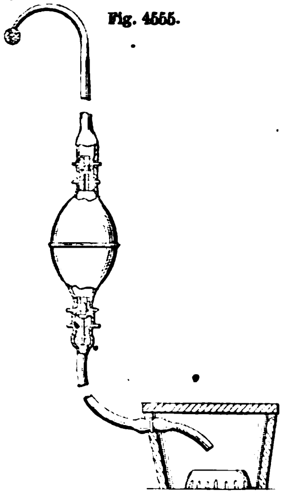
Sa-li'va-pump. (*Dentistry.*) A device to remove the saliva from the mouth during dental operations. The tongue and cheeks are kept from contact with the teeth of the lower jaw, and the saliva drawn off by an air-pump through a perforated tube into a receiver. The air-escape valve is between the receiver and the exhaust-bulb of the pump.

In Fig. 4555, the rebent upper end of the pipe has a rose head to take up the saliva. A compressible bulb and two valves form the operative mechanism.

Sal'ly-port. 1. (*Fortification.*) An opening cut in the glacis, through which a passage leads by a ramp from the terreplein to the covered way of the interior. A *postern*. An underground passage from a fortification for making sallies from the covered way.

2. (*Nautical.*) A port for entering or leaving a vessel.

Fig. 4555.



Saliva-Pump.

Sal'ly-port Sledge. (*Fortification.*) A sledge used for hauling ordnance, ammunition, etc., up the ramps, etc., in fortifications.

Sal'mon-lad'-der. A chute for salmon to ascend falls and weirs. It has usually a broken or a sinuous descent. A *fish-ladder* or *fish-way*.

Sal'mon-stair. A zigzag channel on the face of a weir to assist fish in ascending the same. A *fish-ladder*.

Sa-loon'-car. (*Railway Engineering.*) A passenger-car fitted up with sofas and chairs, to afford first-class accommodation for those able and willing to pay extra for it. A *drawing-room* or *palace car.*

Salt-block. An apparatus for evaporating the water from a saline solution. The technical name for a salt-factory.

Salt'ern. A salt manufactory where water is evaporated from brine and dry salt obtained.

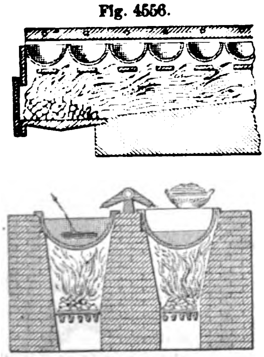
More especially a plot of retentive land, laid out in pools and walks, where the sea-water is admitted to be evaporated by the heat of the sun's rays.

The operation is concluded in boilers.

Salt-fur'nace.

The simplest form of this apparatus, where artificial heat is employed, is probably that of West Virginia or Syracuse, N. Y., where the brine is pumped from a great depth of the earth and conducted by pipes to the kettles, which are in two long rows, built into the top of a furnace, which is 150 feet in length, having the furnace doors at one end and a chimney at the other. The iron pans are heavy and shallow, and may be from 80 to 100 in number. As the water evaporates, the salt is precipitated, and is dipped out into baskets, which are placed in pairs over the pans, in order that the salt may drip and dry. The salt is then emptied into the bin and shoveled into barrels for transportation.

Fig. 4556.



Salt-Furnace.

The brine which supplies the salt-works of Moutiers, in the Tarantaise, Switzerland, has only 1.83 per cent of saline matter, $1\frac{1}{2}$ pounds to 13 gallons of water. (The water of the North Sea in Europe has 2.25 per cent.)

To condense this attenuated solution, the brine is repeatedly trickled over fagots of thorn placed in frames, being condensed by aërial evaporation to 22 per cent. Another plan there adopted is to trickle the brine down vertical cords, upon which it crystallizes, and the saline cylinder is then broken off. The cords are renewed every 25 years; the fagots, every 7 years.

Salt-gage. A SALINOMETER. See Figs. 4450, 4451, 4452, previous page.

Salt-glaz'ing. (*Pottery.*) A glaze for earthenware, prepared from common salt.

Salt-pan. A salt-pit, or salt-works. An evaporating-pan for salines.

Sal'vage. (*Nautical.*) A skein of hemp, not twisted, but simply bound with yarn; used for tackling of cannon, and other purposes where great pliancy and strength are required. *Selvagee.*

Sal'ver. (*Household.*) A kind of tray or waiter, used for table service.

Sa'mite. (*Fabric.*) A heavy silk embroidered stuff. *Samette.* The name is from the Greek *ἑξάμιτος*, six-threaded, which indicates a peculiar twill in the original goods, given by floating the weft over 5 warps. See DIMITY; TWILL.

"Clothed in white *samite*."
TENNYSON.

Sam'pan. A Chinese punt used on the rivers for conveying merchandise, and also frequently for habitations.

Sam'son-post. 1. (*Shipbuilding.*) A pillar resting on the keelson and supporting a deck-beam.

2. (*Nautical.*) A spar sustained in a vertical position by guys, and used as a *jib* for the suspension of hoisting-tackle, for getting boats or blubber aboard, fishing the anchor, etc.

Sa'nat. (*Fabric.*) An Indian calico.

Sand. (*Founding.*) The sand used by the molder, while it consists essentially of crystalline particles of silica, must contain other substances as well, to give it tenacity when damp, and when subsequently dried. Clay plays the most important part; it is a common constituent of the sand as found in its natural bed. In this respect, different kinds of sand differ exceedingly, and they have to be mixed in suitable proportions, and (for iron molding) additions of powdered coal or coke made to adapt the sand to each specific purpose.

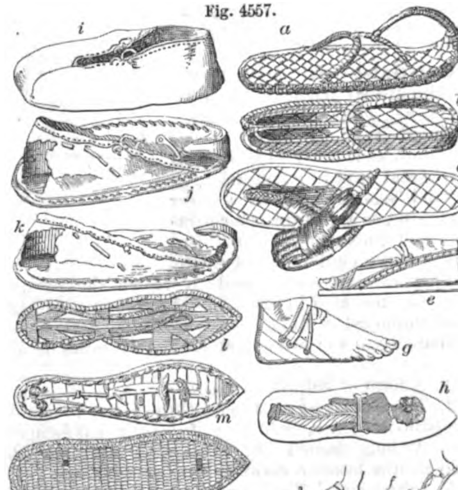
Sands for different purposes or kinds of work receive specific names, as, —

Core-sand, *dry* sand, *facing*-sand, *green* sand, *new* sand, *old* sand, *strong* sand, etc., which see under their respective heads. See also LOAM.

San'dal. A protection for the sole of the foot. It consists merely of a sole, with sometimes a shield at the toe and heel, leaving the upper part of the foot bare, and is secured by straps passing over the instep and around the ankle. Sandals were worn by the Jews, and most Oriental nations, as well as by the Greeks and Romans, but appear to have been to a great extent supplanted, even among the Orientals, by shoes.

The sandals of the ancient Egyptians are shown in many of their paintings at Medinet-Aboo and elsewhere.

Fig. 4557.



Egyptian and Assyrian Sandals and Shoes.

In the Abbott Collection (New York Historical Society) are old Egyptian sandals made from date-leaves, papyrus, leather, and raw-hide. Also boots and shoes of purple leather, white kid, and red leather.

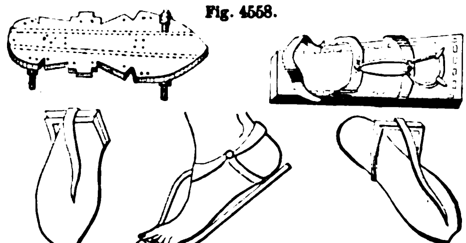
Their common sandals were of papyrus or palm-leaves; those of the Greeks and Romans of willow. The *baxa* was the sandal of the comedian; the *cothurnus*, of the tragic actor.

The priests of Egypt eschewed leather for sandals, as the contact of anything that had died was defilement.

A number of examples are given in the cut annexed. *a* is a handsome sandal with the usual instep strap and the cord which reached from the latter to the sole, passing between the great toe and the second one. *b* assumes the shape of a shoe, having sides and no straps between the toes. *i j k* are distinctly shoes. *c* is the common sandal of the people.

The common sandal, in Oriental countries, is made of a piece of hide from the neck of a camel, and sometimes of several thicknesses sewed together. It is fastened by two straps, one of which passes between the great and the second toe, and the other

Fig. 4558.



Sandals.

around the heel and over the instep; hence it was easily slipped off when the "latchet" was "unloosed" (Mark i. 7). The direction of the angel to Peter, "Bind on thy sandals" (Acts xii. 8), indicates the style of fastening, even did not contemporary statuary show the form with perfect clearness.

While many ladies were shod with ornamental sandals, which were sometimes like pattens to raise them above the dirt of the street or the dampness of the bath-room floor, it is probable that some wore buskins, or moccasins, as we should term them, and that such were alluded to in Canticles vii. 1: "How beautiful are thy feet with shoes." They were probably worn by Judith when, as it is said, her sandals ravished the eyes of Holofernes. Badger's skin is referred to by Ezekiel (xvi. 10) as a choice material therefor.

On the sculptures of Nimroud the king is represented wearing sandals. Those of the Emperor Augustus were *rights* and *lefts*. He esteemed it an ill omen that he accidentally misplaced them. The pillar or thong between the big toe and its neighbor would early suggest making them specially for each foot.

The Assyrian sandal *e* had a long counter and a sole, fastened to the foot by means of bands around the instep, in some cases aided by straps which passed forward to the ball of the foot or between the largest and the second toes. They were of wood or leather. In Egypt, palm-leaves and papyrus-stalks were employed in addition to leather. The soles of the Assyrian sandals were flat; those of the Egyptians were frequently turned up at the toes, as at *f*. *g h* are also Assyrian; *l m n*, Egyptian.

San'dal-brick. A local name for imperfectly burnt brick. *Sandel, samel, place, pecking* brick.

Sand-bag. 1. (*Fortification.*) A canvas sack filled with sand or earth, and used in fortification.

Sand-bags are used as a cover for troops, as a revetment for parapets and embrasures. They usually contain a cubic foot of earth.

They are extensively used to crown the parapet of earth excavated in *sapping*. 1,000,000 sand-bags were employed in the offensive works at Sevastopol, principally in the protection for the 70 miles of *approaches*.

2. A form of ballast for boats.

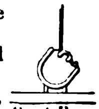
3. The ballast of a balloon, thrown out to enable the balloon to rise, or to keep its level as gas escapes.

4. A long flannel bag filled with sand, used to stop chinks beneath doors or between sashes.

5. (*Sheet-metal Working.*) A flat sack filled with sand on which work is supported while being chased.

6. (*Engraving.*) A similar bag on which the plate is laid and turned about while being operated on with the graver.

Fig. 4559.



Sand-Bag.

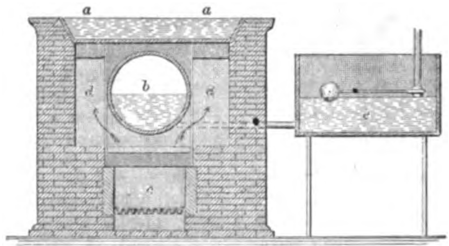
Sand-ball. Soap made up into a ball with fine sand, for washing the hands.

Sand-bath. 1. A vessel of heated sand, used as an equable heater for retorts, etc.

A form of evaporator largely used in laboratories.

Fig. 4560 represents a form of sand-bath in which *a a* is a trough for sand; *b*, a small steam-boiler,

Fig. 4560.



Sand-Bath.

which has a safety-valve not shown; *d d* are hot-air and smoke flues; and *e* a reservoir from which the boiler is supplied with water.

By the use of this or a similar arrangement, an equable temperature may be attained in the bath, and the chemist has always at hand a supply of hot water for purposes of the laboratory.

2. (*Medical.*) A form of bath in which the body is covered with warm or with sea sand.

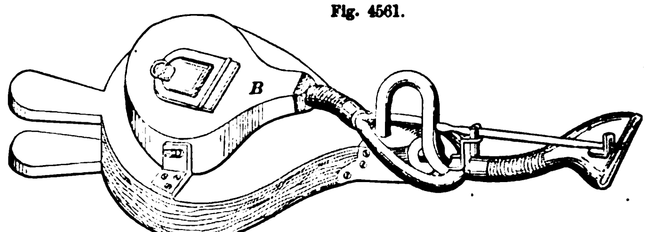
Sand-bed. (*Founding.*) *a.* The floor of sand at a smelting-furnace in which the metal from the furnace is run into pigs.

b. The floor of a foundry in which large castings are made, or on which the flasks are laid, rammed, and poured.

Sand-bel'lows. A hand-bellows used for sprinkling sand on a freshly painted surface to give it the appearance of stone.

The sand from box *B* sifts down into the spout as the upper valve is opened, and is ejected by the blast as the bellows are closed.

Fig. 4561.



Sand-Bellows.

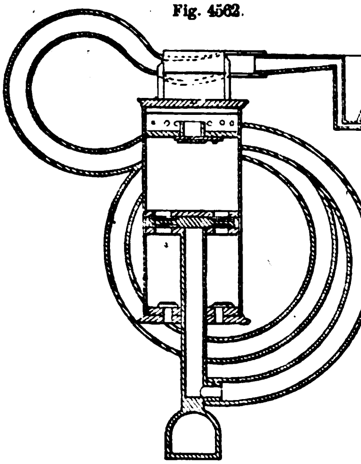
Sand-blast. A method of engraving and cutting glass and other hard materials by the percussive force of particles of sand driven by a steam or air blast. See GLASS-CUTTING, page 978.

For cutting an ornament or inscription on stone, an iron pattern is fastened to the stone, and a movable jet-pipe is caused to traverse the surface of the stone, which it abrades, leaving intact the portions protected by the pattern. Common hard sand is the material employed; but small granules of iron, about $\frac{1}{25}$ inch in diameter, have been found to act more rapidly on granite. Crushed agate is also used.

Sand-blow'er. A device for powdering with sand a freshly painted surface, in order to make it resemble stone.

The piston is chambered, and has inwardly opening valves in its two disks, so that when moving in either direction the air is forced through the tubular piston rod and pipe to the discharge-mouth.

Fig. 4562.

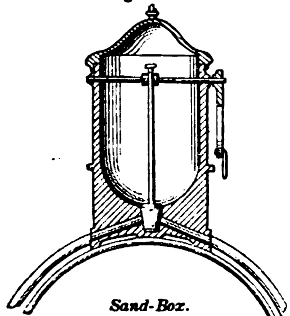


Sand-Blower.

Sand-board. (*Vehicle.*) A bar over the hind axle and parallel therewith. It rests upon the hind hounds where they cross the axle.

Sand-box. 1. A box filled with sand, usually placed in front of the driving-wheel, with a pipe to guide the sand to the rail, to be used when the drivers slip on the rails, owing to frost or wet.

Fig. 4563.



Sand-Box.

In the West, railway-trains have been stopped on a grade by locusts. When the dew falls and the rails are warmer than the grass, these insects have a fancy for sitting on the rails, and when the engine-wheel touches them they are crushed, leaving the rails so soapy that the wheels slip. Sand-boxes are used with the locomotive.

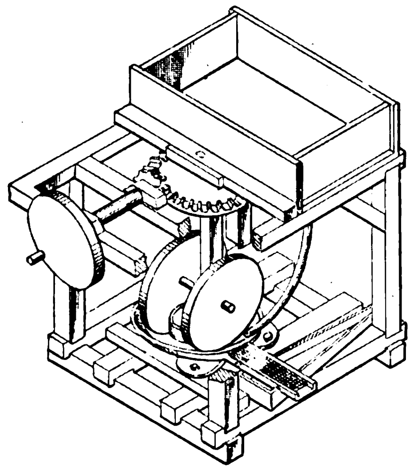
In Fig. 4563, the box has a hemispherical bottom, in the lower part of which is a conical valve-seat, which is closed by a valve of the same form. This valve-seat has two apertures, one on each side of the engine, through which the sand passes, and is conveyed to the rail in front of each driving-wheel.

2. A box with perforated top, for sprinkling paper with sand in manner of a pounce-box.

Sand-burned. (*Founding.*) When the heat of the melted metal cast into a mold affects the surface of the sand so as to subject it to a partial fusion, whereby it adheres to and even unites more or less with the surface of the metal, giving a rough result, the casting is said to be *sand-burned.* This defect is caused by the unsuitable nature of the sand or the want of proper *blacking* on the mold.

Sand Crush'er and Wash'er. A machine for breaking nodules of sand, reducing it to a fineness and washing away foreign matter. The axis of the wheel is attached to a vertical shaft, which rotates in the central opening of the pan, while the wheels traverse in the annular trough, the water assisting in comminuting the mass and washing off the earthy particles. It is especially used in preparing sand for glass-making.

Fig 4564



Sand Crusher and Washer.

Sand-glass. A time-measurer, consisting of a vessel containing a measured amount of sand, which is allowed to escape through a hole of definite proportions so as to occupy a certain time in so doing.

The sand-glass was derived from or suggested the clepsydra, or water-clock, in which the lapse of time was indicated by the escape of water from a hole in a vessel. This was probably the first time-measurer acting mechanically. Previous to this the lapse of time was counted by the dial, by devices such as the counting of pebbles from one helmet to another by the Franks and Norsemen; a measured tread and counted paces; the time required to recite the prayers, as indicated by the beads. See CLEPSYDRA.

The clepsydra assumed various forms.

1. In one case a brass dish with a hole in the bottom was floated in a cistern, and the time required for its filling and submergence formed a unit of time.
2. The emptying of a large brazen vessel, the side of which was pierced with a small hole.
3. A vessel similar to the foregoing, with a float and graduated stem, indicating time by its subsidence.
4. The device No. 3, with the addition of a string from the float, to turn an axis and a pointer finger on a figured dial.
5. A clepsydra in which the escaping water turned a wheel which communicated motion to a hand on a dial. See CLEPSYDRA.

These devices were subject to many difficulties, such as the evaporation of the water, which affected those depending upon the measured amount, and the unequal rate of flow at different stages of fullness of the discharging-vessel.

At what period toothed gearing was invented cannot be readily ascertained. Archimedes used it 220 B. C., and probably saw it in Egypt.

Sand, as the flowing material, is stated by some authorities to have been introduced in France about the time of Charlemagne, but this is an error.

On an ancient bas-relief in Rome an hour glass is placed in the hands of Morpheus. Athenæus says that the ancients carried portable hour-glasses with them.

The term translated *hour-glass* does not warrant the idea that glass was used. The probable material was horn, or the mineral then so much used for windows, laminated mica, the *lapis specularis* of Pliny. The two chambers were probably separated by a plate having a drilled opening. See HOUR-GLASS.

It may be mentioned in this connection that the first dial on record is that of Ahaz, 742 B. C. It was probably derived from Assyria. See DIAL.

The dial is mentioned in the book of Tobit. The date of the writing of this book is not certain, but it details the experiences of an Israelite of Naphtali, a prisoner in Nineveh in the reigns of Shalmanezer and Sennacherib.

The statement of Herodotus that the Greeks derived the sun-dial from the Chaldeans is no doubt correct. In the time of

Ahaz, the communications between Assyria and Palestine were open and well traveled, as the Israelites well knew and felt.

Homer describes the sun-dial, 950 B. C.

The dial was introduced in Athens by Meton, 433 B. C.

By L. Papirius Cursor into Rome, 293 B C

Hipparchus used a dial at Alexandria, 130 B. C.

Augustus set one up on a magnificent scale in the Campus Martius. See DIAL.

San'di-ver. (Fr. *Suint-de-verre.*) A saline scum which rises to the surface of fused glass in the pot, and is skimmed off. Called also *glass-gall; sadwei.*

Sand-jet. A process for grinding and abrading hard substances by the impact of a stream of sand propelled by an air or steam jet.

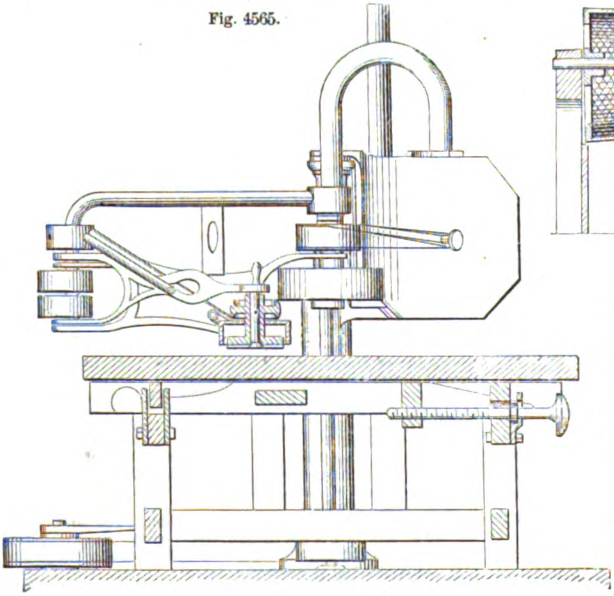
In depolishing glass, the stream of sharp sand is projected by a fan thirty inches in diameter, making thirty revolutions per minute. The air is driven through a chute into which the sand is fed, and from which it is thrown forcibly down upon the glass below the mouth of the chute. From ten to fifteen seconds' exposure to the shower of sand is sufficient to depolish the surface of ordinary glass; and sheets of the latter may be conveniently treated by being passed slowly under the sand by means of endless belts. For cutting stone, the impelling jet is steam; the force given to the sand, and, of course, the rapidity of the cutting effect, being proportioned to the steam pressure. For one hundred pounds' pressure, the sand is most advantageously applied by drawing it through a three-sixteenth inch tube; the steam issuing through an outer tube concentric with that which conducts the sand. This is for drilling holes in hard material; and, with a pressure one fourth greater than that just indicated, one and a half cubic inches of granite are worn away per minute, three inches of marble, and ten inches of soft brown-stone. In cutting corundum with sand driven by steam at three hundred pounds' pressure, a hole an inch and a half in diameter was cut through a piece one and a half inches thick in twenty-five minutes. The process is also used in cleaning the internal surfaces of hollow ware preparatory to tinning. See GLASS-CUTTING, page 978.

Sand-pa'per. An abrading agent made by coating paper with glue and dusting fine sand over it with a sieve. Thin cotton cloth is sometimes used instead of paper. Sand-paper is intermediate between glass-paper and emery-paper in its action on metals, but is less energetic than glass-paper in its action on wood.

GLASS-PAPER (which see) is prepared in a similar way from pounded glass, and is sometimes termed sand-paper.

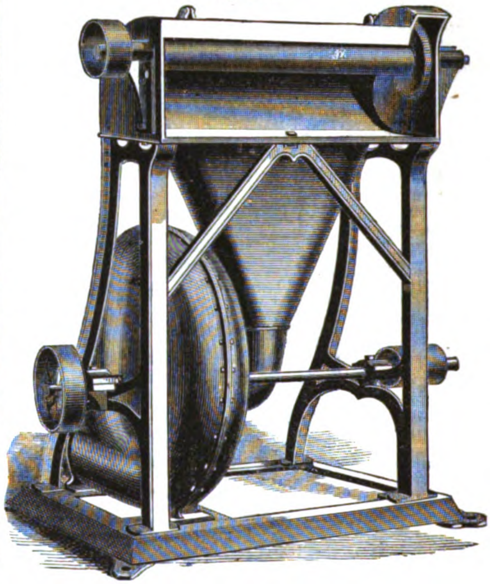
Sand-pa'per Hold'er. A block or pad on which a piece of sand or glass paper is wrapped for use.

Fig. 4565.



Sand-Papering Machine.

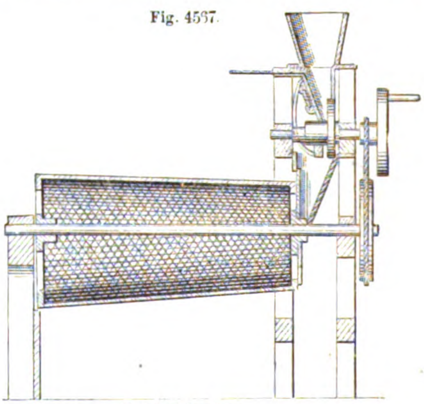
Fig. 4566.



Sand-Papering Machine (Shoe Machinery Manufacturing Co).

Sand-pa'per-ing Ma-chine'. 1. (*Joinery.*) A device for sand-papering flat surfaces. The work is laid on the table, which is vertically adjustable; the sand-paper disk is rotated at the end of a jointed tubular extension arm, which also conducts the dust away, through the hollow arm, to the exhaust-fan.

Fig. 4567.



Sand-Pulverizer.

2. (*Shoemaking.*) For buffing the soles of boots and shoes. Sometimes called *whitening.*

An exhaust fan or blower creates a draft which conducts away the dust caused by the action of the sand-paper roll upon the bottoms of the shoes.

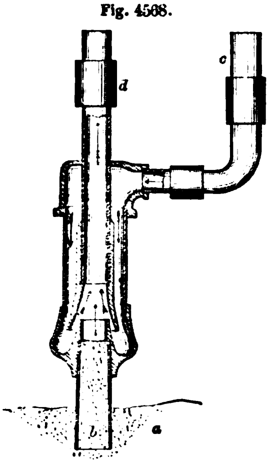
Sand-pul'ver-iz'er. A machine to grind and sift sand for use in glass-making and for other purposes. Fig. 4567 has a grinding-plate working against a vertical yielding bed and a revolving wire-gauze cylinder, by which the sand is sifted.

Sand-pump. A cylindrical case or metallic tube having a valve at bottom opening upwardly. Its office is to remove the sand which collects in the bore when a well is being drilled; the drill being temporarily removed, and as the sand-pump is lowered, the dirt and water force up the valve and enter the tube, the valve dropping again to prevent their return. This being repeated again and again, the barrel of the sand-pump becomes filled, is drawn to the surface and emptied. When the detritus is all removed from the bore, the drill is reintroduced and the operation proceeds.

The sand-pump is described in Good's English patent, 1823. It is there called a *shell* or *shell-pump*. It is called by the French, *emporte-pièce*. See SHELL-PUMP.

The Chinese have had deep-bored wells for ages; we cannot suppose that they have failed to use this device for withdrawing the detritus. The wells of Ou-Tong-Kiao in China are numbered by hundreds, are 5 or 6 inches in diameter, and over 1,000 feet deep.

Fig. 4568.



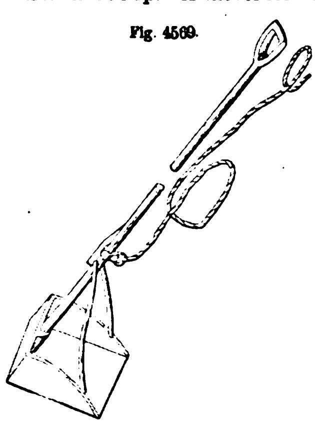
Sand-Ejector (*St. Louis Bridge Caisson*).

The sand-pumps, used for removing the sand from the caissons of the St. Louis and Illinois bridge, as the piers descended, were of three-inch bore, each discharging ten cubic yards of sand in an hour, and gravel stones two and a quarter inches in diameter. A stream of water was forced down through one pipe, and caused to discharge near the sand into another pipe in an annular jet, and in an upward direction. The jet created a vacuum below it, by which the sand was drawn into the second pipe or pump, the lower end of which was in the sand. The force of the jet drove the sand up to the surface as fast as it entered the second pipe. See AIR-LOCK; CAISSON.

Sand-roll. One for a rolling-mill, for instance, — cast in sand, as distinguished from a *chill-roll*, one cast on a chill.

Sand-scoop. A shovel for obtaining sand from the bottom of a river. A form of dredge. In Fig. 4569, the staff rises perpendicularly from the rear end of the scoop, and has a collar to which the hoisting-rope is attached. The rope has a series of loops to engage over a pin on the boat, and the rope attachment to the staff forms a fulcrum in the use of the scoop. See Fig. 517, DREDGING-MACHINE, page 747.

Fig. 4569.



Dredging-Scoop.

Sand-shot. (*Ordnance.*) Small cast-iron balls, such as grape, canister, or case, cast in sand. Larger balls are cast in iron molds.

Sand'stone. An aggregation of siliceous grains, sometimes cohering without visible cement, but usually bound together by a slight quantity of siliceous or calcareous matter, or by iron or clay.

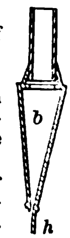
Nature shows all gradations in texture. When coarse-grained, it is called *grit.* When the fragments are so large as to form pebbles, it is called *conglomerate* or *pudding-stone*, which may consist of one or several kinds of rock.

Micaceous sandstone has little plates of mica, which are sometimes in layers parallel to the stratification.

Calcareous sandstones are those in which the siliceous grains are cemented by carbonate of lime, or in which the particles are partly siliceous and partly calcareous.

Sand-throw'er. An implement for sanding sized or painted surfaces. The example has a hollow handle, which contains a supply of sand that is received in a V-shaped box *b*, having a narrow slit with a projecting lip *h*, by which the sand is distributed.

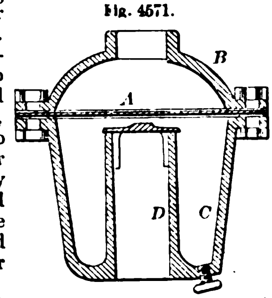
Fig. 4570.



Sand-Thrower.

Sand-trap. (*Hydraulic Engineering.*) A device for separating sand, etc., from water flowing through a pipe. In Fig. 4571, the water enters the trap through the valved induction-pipe *D*, and, flowing upwardly into the dome-shaped cover *B*, is conducted off by another pipe; the sand is detained by the diaphragm *A*, and settles in the annular reservoir *C*.

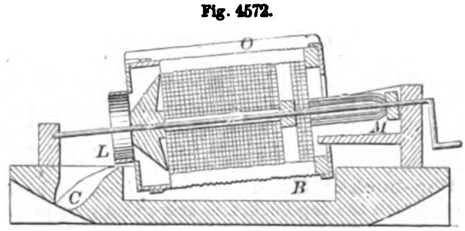
Fig. 4571.



Sand-Trap.

Sand-wash'er. A device for separating earthy matters from sand. In Fig. 4572, a cylindrical wire screen having exterior wings *O* is rotated in a trough *B*, to which a constant supply of water is admitted through a chute *M*; soluble matters passing through the meshes of the riddle are carried off by the chute *C*, and other foreign particles are discharged by the tail-spout *L*.

Fig. 4572.



Sand-Washer.

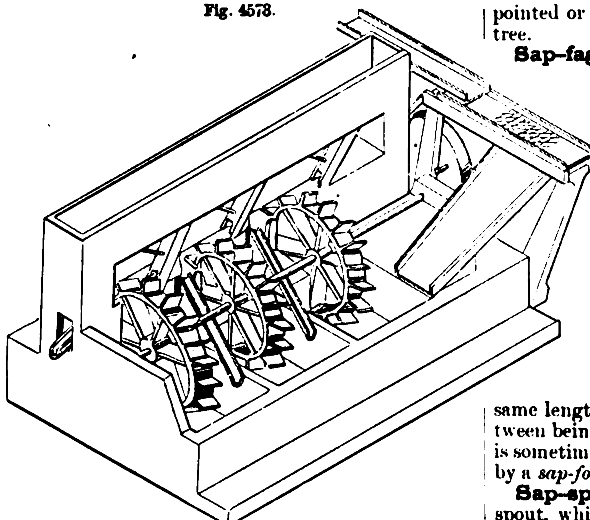
In Fig. 4573, the sand, after being screened by a shaking riddle, passes down a chute to a series of troughs having wheels rotating on a common axis, by which it is agitated and successively transferred from one to the next, being cleansed by the action of water at each step.

Sand'wiched. Said of a rail or lamina which is interposed between two sleepers or thicknesses.

Sap. (*Fortification.*) An excavated trench or tunnel, for the purpose of approaching a fort under cover of the scarp and parapet formed by the ditch and excavated earth.

At the head of the sapping party is a bullet-proof *sap-roller*, which is pushed along as the sap advances, affording protection to the men.

Fig. 4573.



Sand-Washer.

The *sap* advances by a series of zigzags, so directed as not to be exposed to an enfilading fire from the fortress.

The *approaches* and the parallels are made by sapping, and these sunken roads afford the means for conveying ordnance, ammunition, and stores to and from the advanced batteries, and for marching bodies of troops to and fro.

Sand-bags, gabions, and fascines are employed as revetments or to crown the parapet formed by the excavated earth.

The works in front of Sevastopol consisted of 70 miles of sunken trenches; and no less than 60,000 fascines, 80,000 gabions, and 1,000,000 sand-bags were employed to protect the men working in the trenches and at the different batteries.

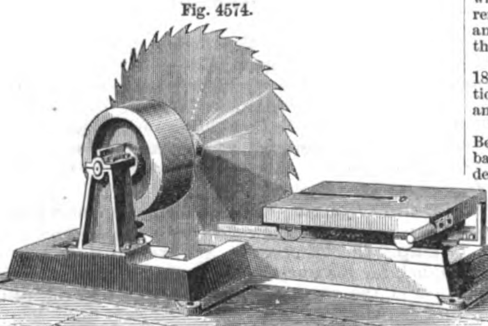
The *double sap* has a parapet at each side.

Sap-boil'er. A furnace with pans for evaporating the sap of the maple. See EVAPORATOR, pages 811 - 813.

Sap-buck'et. (*Sugar Manufacture.*) A bucket for receiving the sap of the sugar-maple as it runs from the tree. Tin pans, earthenware pots, and wooden troughs hollowed out from the log are also employed.

Sap-buck'et Hook. (*Sugar-making.*) A hook from which the sap-bucket is suspended; it has a pointed or screw-threaded end for attachment to the tree.

Fig. 4574.



Sapping-Machine.

Sap-fag'ot. (*Fortification.*) A fascine about 3 feet long, used in sapping, to close the crevices between gabions.

Sap-fork. (*Fortification.*) A forked lever used for advancing the sap-roller.

Sap'ping-ma-chine'. A circular saw for slabbing balks and sawing bolts for shingle stuff.

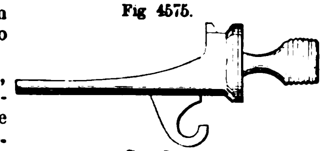
Sap-roll'er. (*Fortification.*) A large roller kept in advance of the men engaged in sapping. It is rolled along at the head of the sap for the protection of the excavators.

The sap-roller is a gabion, 6 feet long and 4 feet in diameter, rendered bullet-proof by an internal gabion of the same length and 2½ feet in diameter, the space between being filled up with stout wooden pickets. It is sometimes stuffed with wool. It is pushed forward by a *sap-fork.*

Sap-spile. (*Sugar-making.*) A small wooden spout, which is driven into an auger-hole bored in the sugar-maple tree, and serves to conduct the sap to the trough or bucket. It is sometimes made of an elder with the pith pushed out; sometimes of wood, bored out.

Sap-spout. (*Sugar-making.*) A device for conducting sugar-maple sap from the tap-hole to the bucket.

Fig 4575.



Sap-Spout.

The spout has, between the holding-screw and the collar, a perforated neck which gives free communication with the outer layer of the alburnum. A hook gives means of suspension for the bucket.

Sar'ce-net. (*Fabric.*) A thin grade of silk goods used for linings, etc. Named from the Saracens. (*Saracenicum,* Latin. Cloth made by the Saracens.) *Sarsenet.*

"With my wife to the new Exchange to buy her some things; where we saw some new-fashion petty coats of sarcenett, with a black broad lace *printed around the bottom* and before, very handsome." — PEPYS'S *Diary,* 1662.

How about balmorals?

Sar-coph'a-gus. A stone coffin.

Sarcophagi were anciently in general use, at least with the wealthy, among the Orientals, particularly those inhabiting the eastern shores of the Mediterranean, and were often ornamented with elaborate and expensive sculptures. Large numbers yet remain in that part of Syria which formerly belonged to Tyre and Sidon, though the ancient cemeteries have for ages supplied the later inhabitants with stone for economic uses.

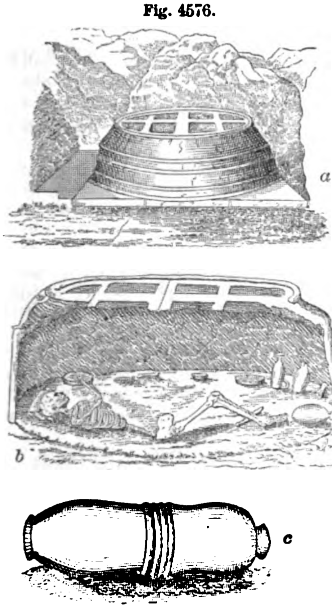
The sarcophagus of King Ashmunazer, discovered at Sidon in 1855, is interesting as containing the longest Phœnician inscription known to exist, until the Moabite stone, since discovered, antedated it. See PEN.

The sarcophagus of Setei-Menephthah was discovered by Belzoni in a deep recess of a tomb. It is of Oriental alabaster, and is covered with some thousands of figures, evidently a funeral procession. It was long in the museum of Sir John Soane, Lincoln's Inn Fields, London. It had been broken open by robbers, probably many centuries before the visit of Belzoni. The body was gone, and the lid broken into five pieces.

In Fig. 4576, *a* represents a Chaldæan clay coffin or vault-cover found at Mugheir, eight feet below the surface of the soil. *b* shows the interior on an enlarged scale. On a platform of sun-dried brick is laid a mat, on this the skeleton or pair of skeletons, surrounded by utensils or ornaments. A huge cover of burnt clay inclosed the whole. In the particular instance illustrated, the contents, besides the skeleton, were a sun-dried brick for a pillow; a copper

bowl; small cylinders of meteoric stone; pieces of bamboo; baked clay jars and utensils for food and water; remains of date-stones in a shallow dish. *c* is another kind of Chaldæan sarcophagus, formed of two large open-mouthed jars, two and a half to three feet in depth and two feet in diameter. The mouth

Fig. 4576.



Chaldæan Sarcophagi.

of the smaller is inserted in that of the larger, and luted with bitumen. In each coffer is a small hole for the escape of the gases of putrefaction. This form is common at Mugheir and Tel-el-Lahm. — *Journal of the Asiatic Society*, XV. 413, 414.

Sa'ree. 1. A cotton fabric worn by East-Indian women wrapped about the person.

2. A long scarf of embroidered gauze or silk.

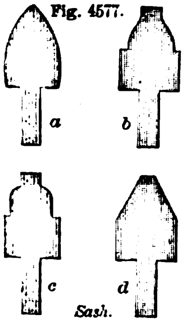
Sark'ing. (*Building.*) The sheathing of a roof above the rafters, and affording a hold for the nails which secure the shingles or slates.

Sar-rus'o-phone. (*Music.*) A form of wind-instrument of the horn class, made by Gautrot Ainé and Cie, Paris. They are made *en suite*, of sizes and compass to take different parts in concerted pieces of music, and are known as the cornets and saxhorns by names, as soprano, contralto, tenor, barytone, bass, etc.; or by the pitch, as *b* flat, *e* flat, etc. See *a*, Fig. 2564.

Sarse. A fine sieve.

Sash. 1. (*Carpentry.*) A frame for holding the glass of a window. The side pieces are the *stiles;* the top and bottom pieces, *rails;* and the interior pieces, which hold the panes, *bars.*

Fig. 4577.



Sash.

There are two kinds of sash:

1. *French sash* or *casement;* hung upon hinges so as to swing open like doors.

2. *Sliding sash;* opening and shutting vertically. When suspended by weights and cords passing over pulleys, they are said to be *hung.*

a. Double hung; both sashes being movable.

b. Single hung; one sash only being movable.

c. Balanced; when each sash has a counterpoise weight, so that it is readily lifted; or the two sashes are made to counterbalance each other. In the former case, the sashes may be lifted or depressed independently; in the latter case, they move together, closing or opening simultaneously and in the same degree.

a, Gothic sash. *c*, ovolo sash.
b, ogee sash. *d*, square-bevel sash.

2. The *gate* in which a mill-saw is strained and reciprocates.

3. An ornamental girdle worn over the shoulder like a baldric or around the waist.

Sash-bar. (*Carpentry.*) The vertical and transverse pieces within a window-frame which hold the panes of glass in place. They are rabbeted or grooved on one side to receive the glass, and are mitered to each other and to the frame. See SASH.

Those for the Crystal Palace, in 1851, were made by a special machine devised by Paxton and Birch, in which a series of revolving cutters shaped a piece which was afterward divided by circular saws into four parts, each constituting a complete bar, other saws of less diameter at the same time making the grooves for the glass.

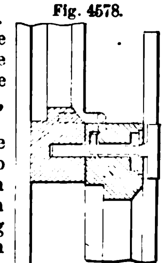
They were painted by drawing them through a trough filled with color, and afterward passing them between a series of brushes set at right angles to each other, which removed the superfluous paint.

Sash-bor'ing Ma-chine'. A machine for boring holes in the stiles of sashes for reception of the bars. It may be preliminary to mortising.

Sash-chis'el. (*Carpentry.*) A chisel having a narrow edge and a strong blade, for making the mortises in blind and sash stiles.

Sash-fas'ten-er. (*Building.*) *a.* A device at the meeting rails of sashes, to prevent a sash from being opened. Usually a sort of turn-button on one sash which locks over the top of the lower sash. In the example, the sashes are locked together by a pin, which transfixes them.

Fig. 4578.



Sash-Fastener.

b. A device on the edge of the sash which locks against it, to maintain it at a given hight. In Hammond's, the edge of the sash is notched and engaged by a spring piece, which may be withdrawn when the sash is to be lowered.

An ordinary form is a snail-shaped piece on the sash which locks against the jamb.

Sash-fil'lis-ter. (*Carpentry.*) A plane for rabbeting window-sash to receive the panes of glass and the putty, which holds them in place; the illustration shows the rabbet made by the sash-fillister, and also the ovolo molding.

Fig. 4579.

Sash.

Sash-frame. 1. The frame, within the window-casing, in which a sash slides.

Sash-frames are *cased* or *solid.* The former have boxes at each side for the weight. The latter consist merely of strips fastened to the window-jambs. A *sash-casing* consists of four pieces, — the *pulley-piece* and *inside, outside,* and *back-lining.*

The strips which form the sash-slides are the *inside* and *outside beads* and the *parting-bead.*

The parts of a *sash-frame* are the *head, sill,* and *sides* or *casings.*

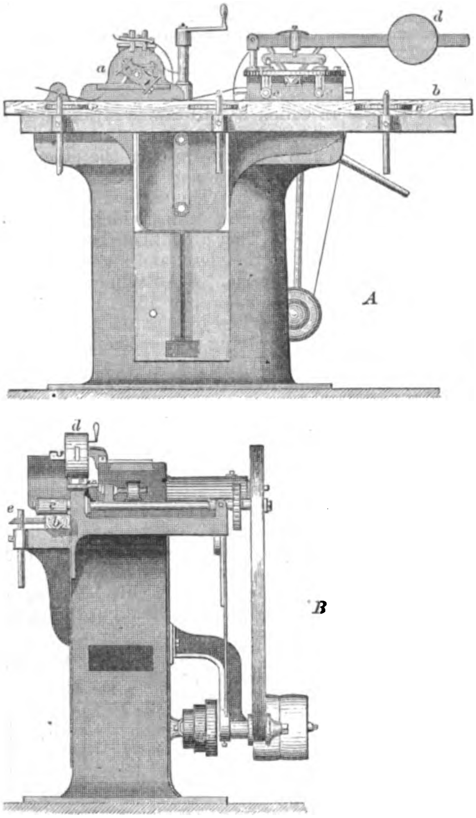
2. The rectangular frame, in which a mill-saw is strained.

Sash-gate. (*Hydraulic Engineering.*) A stop-valve sliding vertically to and from its seat.

Sash-lock. A fastening for the meeting rails of window-sashes.

Sash-mold'ing Ma-chine'. (*Wood-working.*) A machine for planing molds on sash bars and stiles.

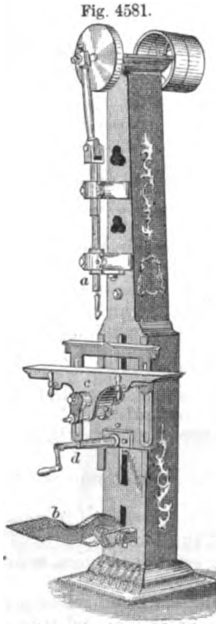
Fig. 4580.



Sash-Molding Machine.

Its size, hight, and proportions particularly adapt it for the work on this small stuff. The views *A B* are respectively side and end elevations of the machine. *a* is the rotary cutter, having bits of such shape as the molding requires; *b* is the stuff going through beneath the rollers *c c*, the pressure of which is determined by the adjustable weight *d*; *c c e* are spring-pieces to keep the stuff against the fence.

Fig. 4581.



Sash-Mortising Machine.

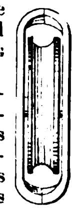
Sash-mor'tis-ing Ma-chine'. (*Wood-working.*) A machine for forming mortises in stiles and rails of doors, sash, and other small work.

In that illustrated, the chisel-holder is reciprocated by pitman connection with a crank on a wheel driven by pulley and belting. The chisel-bar *a* is reversed by a slight movement of the treadle *b*, and the bed *c* may be adjusted to mortise at any desired angle, and is raised or lowered by turning the crank *d*, to determine the depth of cut on work of any dimension within its capacity.

Sash'oon. (*Shoemaking.*) A soft leathern pad placed inside a shoe to ease the pressure on a tender spot.

Sash-plan'ing Ma-chine'. A small form of molding-machine adapted to make the rabbets and molding for the stiles and bars of window-sash. See SASH-STICKING MACHINE.

Fig. 4582



Sash-Pulley.

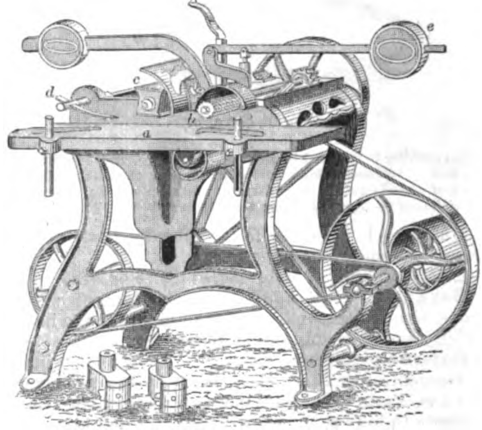
Sash-pul'ley. The sheave in the pulley-piece of a sash-frame over which the weight-cord runs. In the example, the sheave is held between two plates, which have counter projections and depressions on the edges of their incurved ends, and side perforations for reception of the sheave-pivots.

Sash-rail. One of the horizontal bars in a window-sash.

Sash-saw. 1. A mill-saw strained in a *gate*, or *sash*, as it is sometimes called, from the resemblance of its stiles and rails to the frame of a window-sash.

2. A particular size of *tenon-saw* used in making window-sash is known as a *sash-saw*. It is backed with brass instead of iron, and has 13 teeth to the inch. The *tenon-saw* has 8 teeth to the inch.

Fig. 4583.

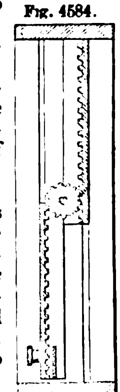


Fay's Sash-Sticking Machine.

Sash-sluice. A sluice with vertically sliding valves.

Sash-stick'ing Ma-chine'. A machine for planing the moldings on the edges of sash bars and rails. The example shows a table *a* on which the stuff slides beneath the feed-roller *b* and cutter *c*. A spring *d* rests on the stuff and prevents chattering. The cutter-head is provided with bits adapted to make the molding required. Two extra cutter-heads are upon the floor. The weight *e* is adjustable on its arm to press the feed-roller upon the work. The bed is gibbed to the frame and raised by a single screw. The machine is also used for planing up small stuff, such as slats and trunk-stuff.

Fig. 4584.



Sash-Supporter.

Sash-sup-port'er. (*Building.*) *a.* A device to hold a sash in an elevated

position. Frequently a spring bolt, which locks into a hole or notch in the sash. Or a cam-shaped piece, which binds against the jamb or strip.

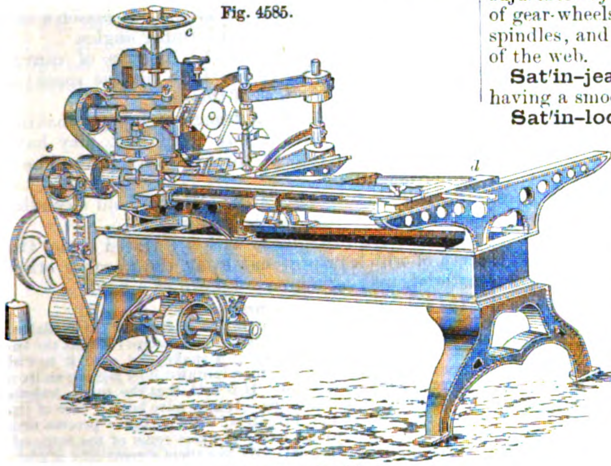
b. A suspension arrangement of cord, weight, and pulley.

A rack and pinion arrangement by which the sashes are made to balance each other.

Sash-ten′on-ing Ma-chine′. A machine for cutting the tenons on sash-slats. Machines of similar construction are used in cutting tenons on slats of Venetian blinds.

In the machine shown in Fig. 4585, the upper and lower cutter-heads raise and lower by a set-screw operated by a hand-wheel *c*, and by this adjustment any thickness of tenon may be made, the carriage *d* remaining stationary as to its vertical adjustment,

Fig. 4585.



Sash-Tenoning Machine.

but sliding easily across the bed of the machine, carrying the slats between the cutters. The upper cutter has an endwise adjustment on its arbor, so as to cut a longer tenon on one side of the slat if desired. The driving-belt *e* passes over the pulleys of both cutters, propelling them at uniform speed.

Sasse. (*Hydraulic Engineering.*) A weir with flood-gates; a navigable sluice.

Sat′in. (*Fabric.*) A silken fabric with an overshot woof and a highly finished surface. It was originally imported from China.

> "What said master Dumbleton about the *satin* for my short cloak and slops? — FALSTAFF.
>
> "The Duchesse of York, sitting in state in a chair, in white sattin." — PEPYS, 1662.
>
> "To church with my wife, who this day put on her green petticoate of flowred sattin, with fine white and black gimp lace of her own putting on, which is very pretty." — *Ibid.*

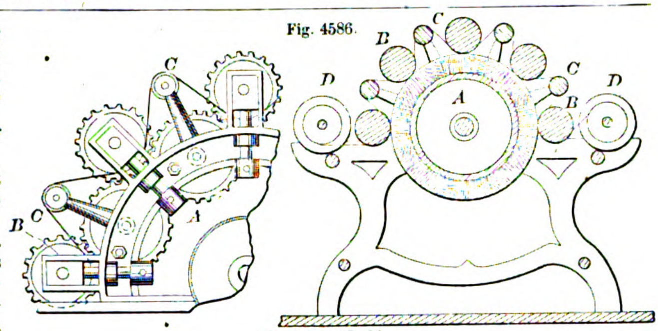
The woof of satin is coarse, and is hidden underneath the warp, which forms the surface. The *warp* is of *organzine;* the *weft* of *tram*. In a full satin twill there is an interval of fifteen threads. See TWILL.

Sat-i-net′. (*Fabric.*) *a.* A light kind of satin.

b. A glossy cloth made of a cotton warp and woolen filling to imitate *satin*.

Sat′in-ing-ma-chine′. (*Paper-making.*) A machine for imparting the "satin" finish to paper.

Fig. 4586.



Satining-Machine.

The web from the roller *D* is presented by the rollers *B B* to the action of the brush *A*, which rotates in the same direction, but with greater velocity, and is raised therefrom by the rollers *C C*, being finally wound upon the second roller *D*. The rollers *B* are adjustable by set-screws, and are rotated by a series of gear-wheels, while the rollers *C* run loose on their spindles, and are turned by the onward movement of the web.

Sat′in-jean. (*Fabric.*) A twilled cotton goods, having a smooth, satiny surface.

Sat′in-loom. (*Weaving.*) The satin-loom has at least a *five-leaved* set of heddles, with corresponding treadles, which are so operated that the shuttle passes over one and under four or more of the warp-threads at each throw. The upper is the glossy side.

Sau′cer. 1. (*Hydraulic Engineering.*) A flat caisson or camel which, being sunk and placed beneath a vessel, is then pumped out, so as to raise the vessel. By another mode of operating, the *saucer* is raised by the power of hydraulic presses, so that the water *runs* out of it.

2. (*Nautical.*) An iron bed bolted to the deck below that on which the capstan works, for the purpose of securing the pivot of the capstan.

3. A shallow piece of table service, forming a support for a teacup.

Sau-cisse′; Sau-cis-son′. (*Fortification.*) *a.* A powder-hose for communicating fire to a charge in military mining.

b. A stout and long fagot, larger than a *fascine*.

Sau′sage-fill′er. (*Domestic.*) A small machine for stuffing sausage-meat into intestines. See SAUSAGE-STUFFER.

Sau′sage-grind′er. (*Domestic.*) A machine for mincing meat for sausage.

Sau′sage-ma-chine′. A machine for grinding, mincing, or pounding meat to make sausages. In the vernacular, these are "either in guts or dabs."

Axionicus, in the "Chalcis," quoted by Athenæus, A. D. 220, says: —

> "I am making hash,
> Putting in well-warmed fish, and adding to them
> Some scarce half-eaten fragments; and the pettitoes
> Of a young porker, and his ears; the which I sprinkle
> With savory asafetida; and then
> I make the whole into a well-flavored sausage,
> A meat most salable. Then I do add a slice
> Of tender tripe; and a snout soaked in vinegar."

De gustibus non est disputandum.

The sausages of Heliogabalus were a compound of oysters, lobsters, crabs, and shrimps, flavored with delicious condiments, — black pepper, anise-seed, garlic, asafetida, ginger, rue, and anchovies.

Some people, following the Pennsylvania Dutch process, to go no farther back, use the anchydle or cœcum of the entrails

of the ox as an envelope for sausage. To such — and there are very nice people who stuff sausage into guts and things, even into linen bags — let us commend the following, which is a recipe as old as Heliogabalus: —

"A Hog's Paunch.

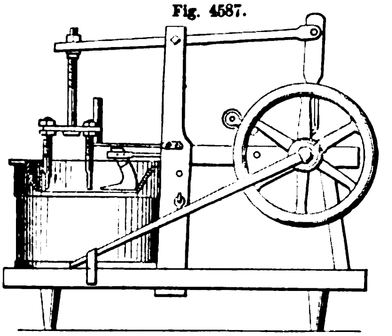
"Having cleansed it well, wash it, first with vinegar and salt, and afterward with water. Then take the hog's flesh pounded into a paste; mix it with the brains of three hogs, cleansed from the fibers, together with hard eggs. To this put cloves of garlic; add whole pepper, and make of a proper consistence with broth. Beat up pepper, lovage, assafetida, anise-seed, ginger, rue, anchovies, and a little oil. With this stuff the paunch. Tie the mouths of the paunch and boil. Prick with a pin to prevent bursting. Then smoke it."

"Here 's richness!"

The old plan was to cut the meat by means of cleavers, one in each hand, a practice in which some persons attained great dexterity. In early times in the West, sausage was cut on the block by an axe. This was much slower than the handy little pair of cleavers, which were kept for that purpose, and went the round of a settlement when hog-butchering began.

The earlier forms of sausage-machines used cleavers, which were at first on levers, tripped by cam movement from the main shaft (see Fig. 3106, page 1415). Afterward, knives were made

Fig. 4587.



Sausage-Machine.

to reciprocate vertically by means of crank and shaft. There are many modifications of this form. The tub usually rotates beneath the knives, so as to bring all the meat in succession beneath the cutters; a scraper lifts the meat and turns it over, so that the knives shall not repeat the blow in the same place. See Fig 4587, and Fig. 3107, page 1415.

The favorite domestic form is a compact little machine. It is either a spiral row of studs projecting radially from a barrel and forcing the meat between knives projecting inwardly from the casing;

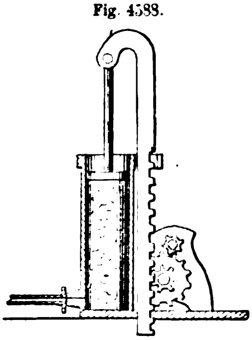
Or it has a series of radial knives on each of a pair of cylinders, and placed so as to make a shear-cut against each other (Fig. 3109, page 1415);

Or the single barrel has knives which cut against opposed edges inside the case (Fig. 3110).

In each case a spiral vane forces the meat through the machine, which is cut as it passes along, and is discharged at the end opposite that at which it was fed in.

Sau'sage-stuff'er. (*Domestic.*) A device for stuffing cleaned intestines with sausage-meat.

Fig. 4588.



Sausage-Filler.

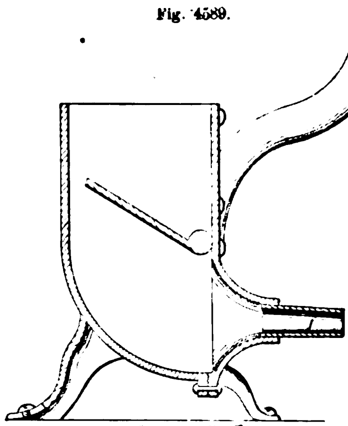
Among the kinds may be enumerated: —

The *piston*, which is moved by a lever or rack-bar, forcing the minced meat out at the spout, over which the gut is forced, and from which it slips as it is filled.

The *rotary*, which resembles in essential structure the rotary pump.

The *hinged valve* (Fig. 4589), which oscillates 180° in the hopper, folding against the side while filling, and then, as the handle is vibrated, forcing the meat out of the nozzle into the gut.

Fig. 4589.



Sausage-Stuffer.

Saute-relle'. (*Stone-working.*) A mason's implement, used in tracing and forming angles.

Save-all. 1. (*Nautical.*) A strip of canvas which may be laced to a sail to fill the *roach* or upward curve of the foot of the sail.

2. (*Paper-making.*) A trough in a paper-making machine which collects any pulp that may have slopped over the edge of the wire cloth in the Fourdrinier machine.

3. A little tube and flaring collar to hold a candle-end in a candlestick while burning.

Saw. An instrument with a serrated blade, the teeth of which rasp or cut away the wood or other material, making a groove known as a *kerf*.

The wasp was perhaps the first sawyer.

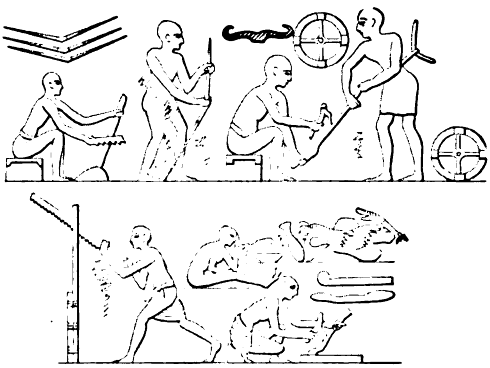
The Grecian myth of the invention of the saw (by Dædalus, *Pliny;* Talus, nephew of Dædalus, *Apollodorus*) is that the inventor once found the jawbone of a snake, and used it to cut through a piece of wood; he then imitated it by jagging an iron plate, and thus made a saw. It is said that the uncle, jealous of the discovery, killed Talus. It may have been a case of interference between two inventors, with irregular process and short shrift. Researches in Egypt upset some of the tattle of Pliny and others of his day. We owe them a great debt of gratitude, however.

Other writers say that Perdix, nephew of Dædalus, employed the backbone of a fish, and was thus led to the invention. Perdix raised the jealousy of somebody, and was changed into a partridge. Ovid mentions this, without assigning the name of the inventor.

Saws of the bronze age have been discovered in Germany and Denmark, but not in Great Britain. (Lubbock.) The metal was cast thin, and probably was serrated by chipping and grinding.

Saws of the stone age were made by setting flakes

Fig. 4590.



Egyptian Sawyer and other Mechanics (from Thebes).

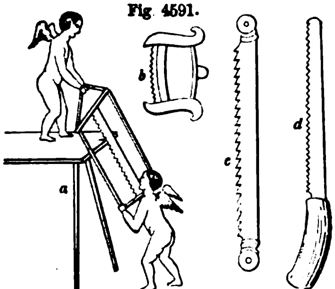
of flint in wooden handles and securing with bitumen. Obsidian was used in Mexico. Saws and knives of obsidian have been disinterred in the alluvial ground of New Jersey beneath the recent gravel. They are held to prove the existence of extensive coastwise trade, as no obsidian is found nearer than Mexico. The saws of the South Sea islanders in 1768, when Captain Cook went to Otaheite to observe a transit of Venus, were made of sharks' teeth lashed to a back-piece. The saws of the Lacustrians and other early inhabitants of Europe were of jagged flint; those of the Caribs, of notched shells. The saw is a very old device, as old as a knife with a ragged edge.

Fig. 4590 is from a group of persons represented in an ancient painting at Thebes, who are making poles or carriage-tongues.

In dividing a beam of moderate length into planks, it seems to have been usual with the ancient Egyptians to set it upright between posts, to which it was lashed. Wilkinson failed to find any saw adapted for use by two persons, like the pit-saw.

g, Fig. 3032, page 1379, represents a saw discovered by Mr. Burton at Thebes, and now placed in the British Museum. The owner had probably been dead several hundred years before Pythagoras, Solon,

Fig. 4591.



Ancient Saws.

or Plato visited Egypt to study science. The ancient saws were *hand* and *frame*.

a. From a painting at Herculaneum. Two genii working a frame-saw.

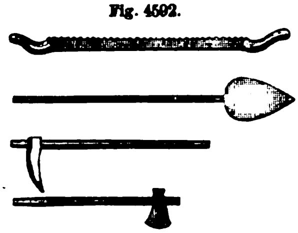
b. A frame-saw from a funeral monument.

c. A frame-saw blade detached; from a monument.

d. An Egyptian saw in the British Museum.

The implements of labor of the Assyrians are not so fully represented on the monuments as those of warfare. The cross-cut saw was two-handled, but not cross-handled, apparently. The shovels were heart-shaped, as at present used in Asia Minor. The picks had single heads. The hatchets had a poll.

Fig. 4592.



Tools of Babylon.

The modern Oriental saw is used with a *drag* rather than a *drive* motion, and the teeth are suitably inclined, raking toward the handle rather than away from it. The ancient Egyptian blade was of bronze, attached to the handles by leathern thongs, and was single-handled. Some of the blades, however, as in the instances of some of the Egyptian saws in the British Museum, are set into the handles with tangs, like our case-knives. The Egyptian saws were operated by the thrust movement, the edge curved or straight. Such are shown in the paintings of ancient Egypt.

St. Jerome is understood to have alluded to circular saws, but the point is not clear.

A double-handled iron saw has been discovered at Nimroud.

Sesorthus was called Aslepius by the Egyptians on account of his mechanical skill. The Greeks derived from him the name and attributes of Æsculapius. He introduced into Egypt the art of building with hewn stone, and, it has been supposed, used saws upon his blocks of stone. This is by no means certain, but we are told distinctly in the Hebrew history that the Phœnician architects of Solomon's temple built it of stone squared with the saw. The marble facing of the palace of Mausolus, king of Caria, described by Vitruvius, is believed by Pliny to have been faced with sawn slabs. This was erected 350 B. C.

Samuel (1033 B. C.) and Isaiah (742 B. C.) refer to saws.

The stone saws were commonly used, and the respective actions of the metal and sand were fully understood, in the time of Pliny. See STONE-SAW.

For *machines*, see SAWING-MACHINE; SAW-MILL; and list *infra*.

Japanese saws are shaped like butchers' cleavers. The handle is flattish, as if whittled out of a piece of inch board; the shank of the saw is driven into the handle, and the whole is secured by being wrapped with fine split cane. The metal of the saw is about the substance of our saws, but the teeth are narrower, giving more of them to an inch, and much longer. The teeth are pointed toward the handle. When a Japanese wants to rip a plank, he places it across anything which will elevate the end a few inches, then stands on the wood and cuts it by seizing the cleaver-looking saw in both hands, and pulling it toward him, working it by short, quick up-strokes.

The very distinguished place occupied by General Sir Samuel Bentham in the history of the invention and manufacture of wood-working machines is evinced by the list of sawing-machines invented and manufactured by him for the British Admiralty previous to 1800.

Circular saw.	Bevel saw.
Segmental circular saw.	Curvilinear saw.
Crown and cylinder saws.	Saw-blade grinding-machine.
Segment sawing-machine with radius arm.	Taper-gage for sawing-machines.
Saw for irregular forms with tracer-guide.	Double-grooving saws.

The circular saw is well described in Miller's English patent, No. 1,152, of 1777.

The band-saw is described in Newberry's English patent, 1808.

See also WOOD-WORKING MACHINES and list under SAW, *infra*.

A circular saw was made with blacksmiths' tools by Benjamin Cummins, at Bentonsville, N. Y., about 1814. This is supposed to have been the first made in this country.

Making a saw involves the following processes: —

1. Cutting out the blade from the sheet.
2. Toothing with a press and appropriately formed dies.
3. Hardening, by plunging while heated in an oil-bath. In this state the metal is extremely brittle.
4. Tempering and straightening; the latter is effected by hammering on an anvil or by compressing several blades, while hot, between two dies worked by a hydraulic press.
5. Grinding and polishing with emery-powder.
6. Filing and setting the teeth.
7. Reheating to restore the elasticity lost in tempering.
8. Removing the scale by immersion, first in dilute acid, and afterward in alkali to remove the acid.
9. The handle is attached and the blade tested.

The plates for saws are made of ingots of steel, carefully prepared to secure uniformity, and reduced to the proper thickness by rolling. Formerly, the larger portion came from Sheffield, England, but Philadelphia, Pittsburg, Cincinnati, and other places make them of the best quality, and from American steel of American iron. Circular saws were employed by Brunel in his block-making machine, and afterward came into general use. The plates for these vary in thickness from $\frac{1}{32}$ to $\frac{1}{4}$ inch, according to purpose, and the diameter from 8 to 72 inches; though sometimes they are made 88 or even 100 inches in diameter. The materials employed are steel and iron scraps of the best quality, melted together, and after casting reduced by repeated rollings. The hole in the center is drilled out, and the teeth roughly cut out by dies under a powerful press, after which the plate is firmly secured upon a heated table and the teeth pointed and sharpened by an emery-wheel; a farther grinding and polishing operation then ensues, a second and narrower wheel finishing the gullets. They are then tempered by heating until the film of oxide on their surface indicates that the proper temperature is attained, when they are immersed for about five minutes in an oil-bath. The oil is next removed by saw-dust, and the temper let down by reheating and gradually cooling. These processes tend to warp the plate, which must, therefore, be straightened by hammering upon an anvil, their

accuracy being tested by a level. This operation requires great care and judgment. The saw is then fastened centrally upon a shaft and caused to rotate rapidly against a large grindstone moving in an opposite direction, which dresses off one side to a perfectly uniform surface, when the saw is turned and the other side similarly treated, making the blade slightly thinner toward the center than at the circumference. They are again tested as to planeness, the straightening process repeated if necessary, and afterward polished by being caused to rotate in contact with wooden blocks coated with a composition of glue and emery.

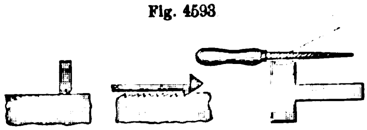
Straight saws are made in a similar manner, regard being had to the difference in shape. The edge intended for the teeth is trimmed true, the teeth punched by a fly-press, filed, tempered, wiped, heated until any remaining oil *blazes off*, hammered on an anvil or *smithed*, ground to a gradually decreasing thickness from front to back (this is now done on both sides at once), re-hammered, again ground or *drawn*, *glazed* or polished, again straightened on the anvil, grained with emery, the teeth set, the blade stiffened by a heating process, any discoloration thus occasioned removed by acids, and, finally, oiled.

For correctly spacing the teeth of fine saws, a double chisel (Fig. 4593) is sometimes employed.

For still more delicate saws, a small piece of steel, hooked rectangularly at one end, is used. Its end is hardened, and serves as a guide for the file.

Piercing and inlaying saws for wood, metal, and ivory are made from pieces of watch-spring; the teeth are laid off and

Fig. 4593



Spacing Teeth of Saws.

filed by laying the saw stretched in its frame flat in a grooved brass plate imbedded in a wooden block; as each tooth is formed the file is shifted angularly and returned to its former position, thus stepping off the interval of one tooth, the spacing being determined by the judgment and skill of the operator.

The French method is about as follows: The blades, after being rolled cold several times, in order to render the grain close and the metal homogeneous, are heated in special furnaces, from which the air is carefully excluded, and when at the proper temperature are plunged in a bath of colza oil; this is done in a dark chamber. The tempering is effected with the aid of machines which cause the blades to pass between cast-iron plates heated to a fixed temperature, according to the nature of the article to be produced. The tooth-cutting, planishing, and grinding are done by machinery, as is also the reducing of joints of ribbon-saws, which is effected longitudinally, instead of across the blade.

Saw-teeth are known, according to shape, rake, interval, set, or other peculiarity, as *peg*, *fleam*, *gullet*, *brier-tooth*, *hawk's-bill*, *skip*, *insertable tooth*, etc.

Fig. 4594 shows varieties of saws and saw-teeth.

Fig. 4594.

The following table shows the dimensions of the generally used varieties of the rectilinear saws, arranged in three groups.

1. Taper Saws, mostly without Frames.

The thickness is that given by the Birmingham wire-gage.

With a Handle at each End.

	Length of Blade.	Width at Wide End.	Width at Narrow End	Form of Tooth (Fig 4641).	Space of Tooth.	Thickness of Metal. Gage No.
	Feet	Inch.	Inch		Inch.	
Cross-cut saw......	4 - 10	6 - 12	3 - 7	*a - d*	¾ - 1	12 - 15
Long, pit, or whip saw..........	6 - 8	9 - 12	3½ - 5	*k l*	½ - 1	12 - 16
Pit-frame saw.....	4 - 6	7 - 11	3 - 4½	......	½ - ¾	15 - 18
Felly or pit-turning saw............	4 - 6	3 - 4	2 - 3	......	½ - ⅝	13 - 15

With Handle at one End.

	Length of Blade.	Width at Wide End.	Width at Narrow End	Form of Tooth (Fig. 4641)	Points per Inch.	Thickness of Metal. Gage No.
	Inch	Inch	Inch.			
Rip-saw...........	28 - 30	7 - 9	3 - 4	*e f*	3½	18
Half-rip saw.......	26 - 28	6 - 8	3 - 3½	......	4	18 - 19
Hand-saw.........	22 - 26	5 - 7½	2½ - 3	......	5	18 - 19
Broken space or fine hand	22 - 26	5 - 7½	2½ - 3	......	6	18 - 19
Panel-saw..........	20 - 24	4½ - 7½	2 - 2½	......	7	19
Fine panel-saw....	20 - 24	4 - 6	2 - 2½	......	8	19 - 20
Chest-saw (for tool-chests)..........	10 - 20	2½ - 3½	1¼ - 2	......	6 - 8	18 - 21
Table-saw.........	18 - 26	1¾ - 2¼	1 - 1½	......	7 - 8	16 - 19
Compass or lock saw	8 - 18	1 - 1½	½ - ¾	......	8 - 9	18 - 19
Keyhole or fret saw	6 - 12	½ - ¾	⅛ - ¼	......	9 - 10	19 - 20
Pruning-saw	10 - 24	2 - 3½	½ - 1¼	*c*	4 - 7	13 - 16

2. Parallel Saws with Backs.

With a Handle at each End.

	Length of Blade	Width of Blade.	Form of Tooth.	Points per Inch.	Thickness of Metal. Gage No
	Inch.	Inch.			
Tenon-saw...............	16 - 20	3½ - 4	*e f*	10	21
Sash-saw	14 - 16	2½ - 3½	......	11	22
Carcass-saw.............	10 - 14	2 - 2½	......	12	23
Dovetail-saw....	6 - 10	1½ - 2	......	14 - 18	24
Smith's screw-head saw...	8 - 8	½ - 1	......	12 - 16	15 - 22

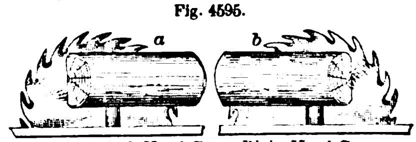
3. Parallel Saws used in Frames.

Stretched Lengthways.

	Length of Blade.	Width of Blade.	Form of Tooth.	Points per Inch.	Thickness of Metal. Gage No.
	Feet.	Inch.		Inch.	
Mill-saw..................	4 - 8	4 - 5	*i l*	½ - 1	10 - 14
Mill-saw web............	4 - 6	3 - 4	....	½ - 1	17 - 20
Veneer-saw	4 - 5	4 - 5	*f*	2 - 4	19 - 21
	Inch.				
Chair-maker's saw........	20 - 30	1½ - 2½	....	3 - 4	19 - 22
Wood-cutter's saw........	24 - 36	2 - 3½	*e*	3 - 4	19 - 22
Continental frame-saw....	15 - 36	1 - 3	*f*	4 - 12	19 - 24
Turning or sweep saw	6 - 22	1/10 - ⅛	....	10 - 20	19 - 24
Ivory-saw	15 - 30	1½ - 3	*e*	4 - 6	22 - 24
Smith's frame-saw........	3 - 12	½ - ¾	*g*	10 - 14	20 - 26
Piercing-saw.............	3 - 5	1/30 - 1/40	*f*	40 - 60	1/100 in.
Inlaying or buhl saw.....	3 - 5	1/25 - 1/30	....	15 - 40	1/70 - 1/100

Fig 4595, *a*, left-hand circular-saw; *i. e.* the direction of rotation is from left to right.

Fig. 4595.



Saws: Left-Hand Saw; Right-Hand Saw.

b, right-hand saw; rotates the other way.

Rail-saws now consist of circular disks about 3 feet in diameter, and driven at the rate of 3,000 revolutions per minute, giving a circumferential velocity of over 5 miles per minute. Steel rails are cut rapidly, giving out abundance of sparks. Such saws are used in America and in England.

Fig. 4596 shows a number of detachable teeth for circular saws. In each case but a portion of the blade is shown. The shape of the teeth and the mode of fastening them in the blades will be understood at a glance.

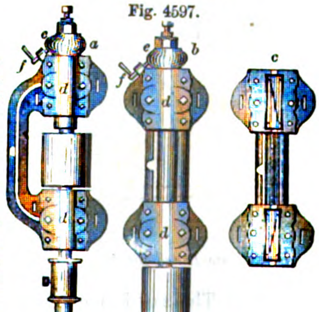
Saw-ar′bor. The axis to which a circular saw is secured and by which it is rotated. *a b*, Fig. 4597, are two different forms. In the first, the pulley which drives the saw is placed between the journal-boxes *d d*, and in

Fig. 4597.

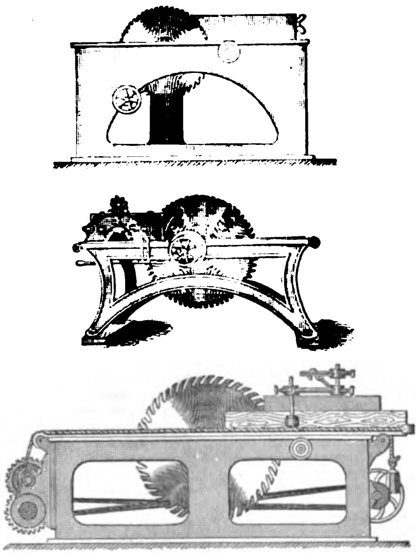


Saw Arbor and Box.

the second outside of them. The device has flanges by which it is bolted to the table. The saw is held between a gland and a nut *e*, and an expanding device operated by a screw at the end adapts the arbor to saws having different-sized holes. A pin-lever *f* prevents the arbor from revolving while removing or replacing a saw. The journal-boxes have a chamber at each end connected by a diagonal recess, in which a piece of cotton-wicking is placed for the purpose of lubrication, as shown at *c*.

Saw-bench. (*Wood-working.*) A table on which stuff is fed to a saw. The examples are several forms

Fig. 4598.

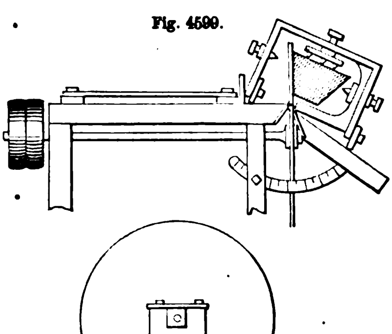


Saw-Benches.

of circular-saw benches, with gages and fences for sawing dimension stuff.

Donkin's saw-bench (English) has a hinged platform in front of the saw, with quadrants by which it may be fixed to any bevel within its range. The parallel rule is available for setting out the widths of

Fig. 4599.



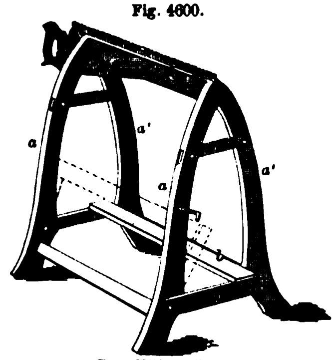
Saw-Bench for Mitered and Beveled Work.

the work. The saw is mounted upon a swing-frame of cast-iron, shown separately in the other figure, and is adjusted by the cam, so as to project the required distance through the slit in the table.

Saw-buck. Another name for the SAW-HORSE (which see).

Saw-clamp. A device, also known as a *horse*, for holding saws while being filed. The standards

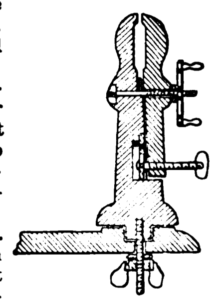
Fig. 4600.



Saw-Filing Clamp.

a a' are hinged together, and are spread apart so as to open the jaws *c* at the upper end, in order to hold the saw. This is pinched tightly by pressing down the treadle *b*, which forces the feet apart and shuts the jaws.

Fig. 4601.



Saw-Filing Clamp.

Fig. 4601 is a form adapted for the bench or table.

Saw-doc'tor. An instrument having an angular punch for cutting pieces out of the edge of a saw-blade, to increase the depth of the interdental spaces. A *saw-gummer.*

Saw'dust-car'ri-er. (*Wood-working.*) A trough or tube by which the sawdust is conducted away from a circular or other saw. See FAN-BLOWER, *A*, Fig. 1918.

Saw-file. A file adapted for saws; triangular in cross-section for hand-saws and *flat* for mill-saws. See FILE, Fig. 1965. The fineness of the file depends upon the character of the work. See list and table, page 840.

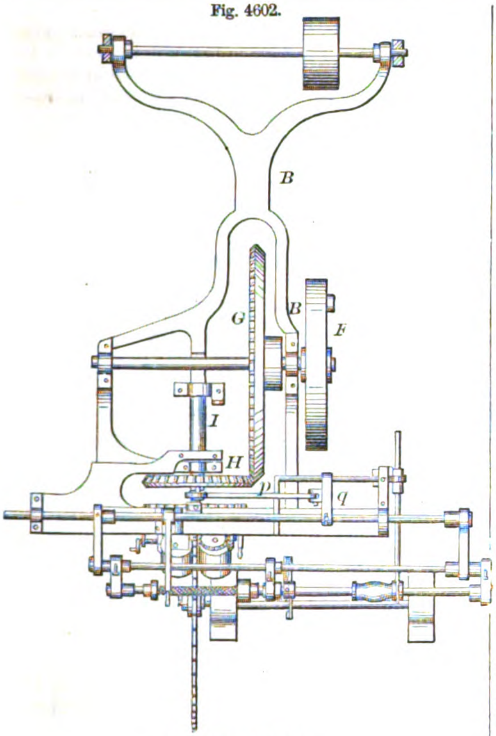
Saw-fil'ing Ma-chine'. One for sharpening the teeth of saws. See also SAW-SHARPENING.

The teeth of saws are usually made by a punching action in a *saw-toothing machine.*

The example (Fig. 4602) has a suspended frame *B* on which the file and operative mechanism are arranged. The axis of suspension is also the arbor of the countershaft pulley, connecting by belt with the driving-pulley *F*. The vertical shaft *I* is rotated by bevel-gearing *G H*, operating the pitman *p* and cross-head *q*, and reciprocating the file-carrier. The saw is temporarily placed on a mandrel on the bench.

Fig. 4603 comprises a standard *a* having a pulley from which a belt passes to a pulley on the movable frame *c*, attached by a ball and socket joint to the main frame *d*. The pulley-shaft carries the grinding-wheel *b*, which, by means of a handle, may be presented to the work at any desired angle. It is driven at the rate of 1,500 to 2,000 revolutions per minute, and is counterpoised by a weighted lever *e*, so as to be manipulated by a slight pressure. See "Art of Saw-Filing" (56 pp.), John Wiley, New York.

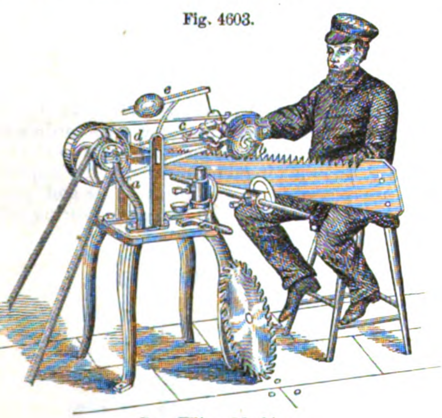
Fig. 4602.



Saw-Filing Machine.

Saw-frame. 1. The frame in which a saw-blade

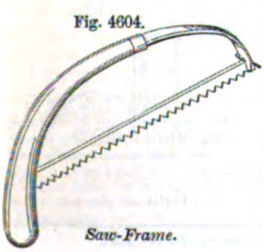
Fig. 4603.



Saw-Filing Machine.

is stretched. In the illustration, this is effected by a stout metallic spring attached to the part which serves for a handle. See FRAME-SAW, page 913.

Fig. 4604.



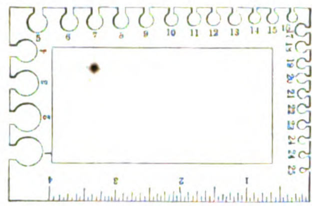
Saw-Frame.

2. The *sash* or *gate* of a mill-saw.

Saw-gage. 1. (*Saw.*) *a.* A test for the thickness of saw-blades or the width of saw-tooth points.

Fig. 4605 is a form of standard saw-gage, also adapted for sheet metals and wire; the central space is open, rendering the gage lighter and affording ready means for hanging up.

Fig. 4605.

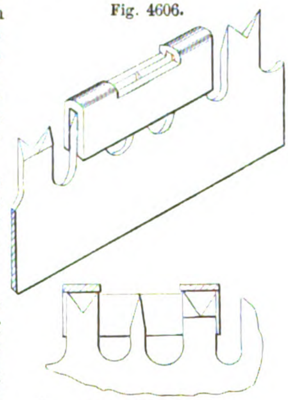


Saw-Gage (drawn to ⅓ Scale, Linear).

b. A test for the straightness of the line of teeth.

Fig. 4606 is a gage to be laid over the line of teeth so as to indicate the exactly proper length of a tooth. In the illustration, the gage lies upon two teeth, and at its notch exposes the middle tooth, which is under treatment.

Fig. 4606.

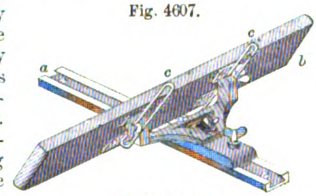


Saw-Filing Gage.

c. A test for the range of teeth-points relatively to their distance from the center of rotation. See Fig. 4643.

2. An adjustable device for governing the width of the scantling or board cut and its angle of presentation to the saw. In Fig. 4607, the former is determined by the position of the gage in the slot *a*. The angle is varied by adjusting the piece *b*, and any desired slope is given by inclining the links *c*. Set-screws are provided for securing each part in the position to which it is adjusted.

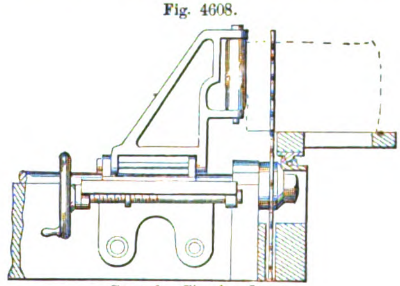
Fig. 4607.



Saw-Gage.

Fig. 4608 is a gage for circular saws. The distance of the rollers from the plane of the saw's motion determines the thickness of the plank.

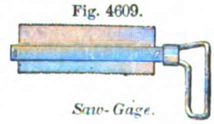
Fig. 4608.



Gage for Circular Saws.

3. A loose back, which is adjusted toward or from the edge of the saw, to limit the depth of the kerf.

Fig. 4609.



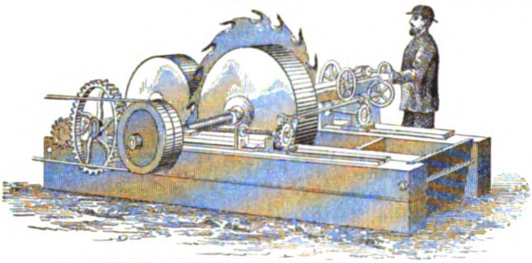
Saw-Gage.

Saw-gate. The rectangular frame in which a mill-saw or gang of mill-saws is stretched. See Fig. 1601. See also SAW-MILL, Plate LIV.

Saw-gin. (*Cotton.*) The original form of cotton-gin, in which the fibers are drawn through the grid by the teeth of a saw. Fig. 1486, page 634, and Fig. 2222, page 969.

Saw-grind'ing Ma-chine'. A machine for dressing the sides of saws, so as to give the blade a

Fig. 4610.



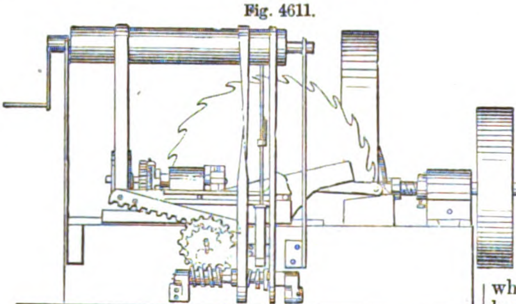
Grinding-Machine for Circular Saws.

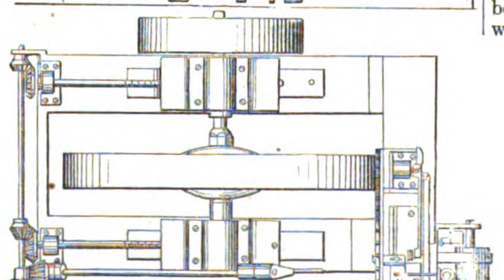
uniform thickness, or impart a uniform taper from center to circumference.

Saw-grinding machines were among those supplied by Sir Samuel Bentham to the British Admiralty, before 1800.

In Fig. 4610, the saw is hung on a spindle, and is caused to rotate between two grindstones in a plane at right angles to their axes. By means of

Fig. 4611.





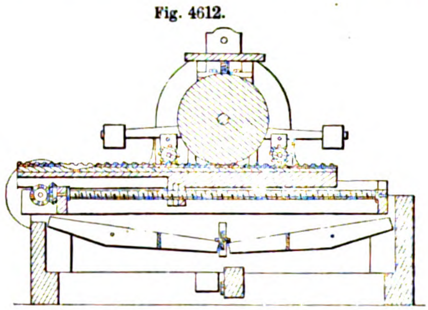
Grinding-Machine for Circular Saws.

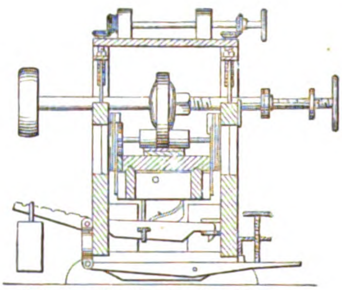
hand-wheels and gearing the grindstones are moved alternately toward and from the center of the saw until it is reduced to the desired thickness.

In Fig. 4611, the saw is on a horizontal mandrel, and receives a motion in two directions, — one upon its axis, and the other by the reciprocation of the carriage that supports the saw. The circular arbor or bearing for the saw is so constructed as to permit the center of the saw to advance to the edge of the grindstone. Thus every portion of the disk is brought in turn to the operation of the grindstone. See also Disston's patent, November, 1874, in which a pair of grindstones grind the face of the saw, and have mandrels so adjustable as to give any required taper, increasing or decreasing from the edge to the eye.

In Fig. 4612, the flat mill-saw blade is placed in position upon the reciprocating bed and beneath the rollers, the force of the levers being then exerted

Fig. 4612.



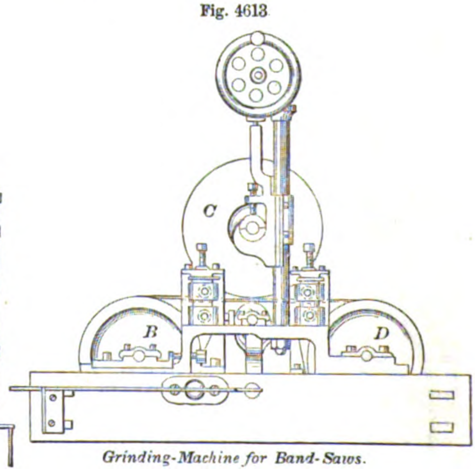


Grinding-Machine for Gate-Saws.

to raise the bed and cause the blade to bear against the rotating grindstone. The rollers confine the blade and its supporting plate to the bed.

Fig. 4613 is for grinding band or ribbon saws, which are placed over the drums *B D* and passed beneath the grindstone *C* above a bearing-roller which supports the blade.

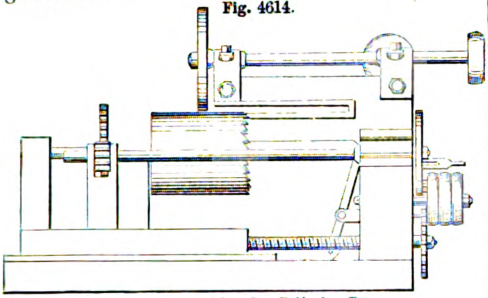
Fig. 4613



Grinding-Machine for Band-Saws.

The machine may also be used for grinding other saw-blades; the metallic apron, in connection with the feed-rollers, moving the saw-blade to the action of the grindstone with a force not greater than the grinding capacity. The flange or collar at the eye of the grindstone may be set in position, or at an inclination corresponding with that of the side of the grindstone.

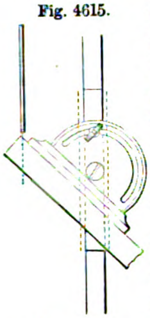
Fig. 4614.



Grinding-Machine for Cylinder Saws.

Fig. 4614 is a machine for grinding cylinder or *tub* saws. The revolving grindstone or wheel is brought in contact with the surface of the cylindrical saw, which slowly revolves and traverses longitudinally from end to end, when its motion is reversed by suitable mechanism. The saw-mandrel has a friction-roller and gage, and the grinding-wheel is adjustable in position.

Fig. 4615.



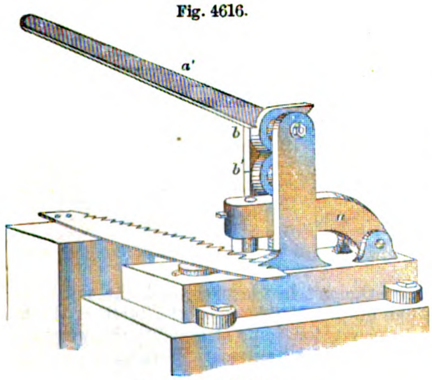
Saw-Guide.

Saw-guide. A piece with an adjustable *fence*, which may direct the saw in cross-cutting strips, against which the piece is laid.

Saw-gum'mer. An apparatus for cutting away the plate of a saw to deepen the interdental spaces. This is sometimes done by punching, sometimes by grinding.

In Fig. 4616, the punch-holder *a* is pivoted and depressed by a lever *a'* operating the cams *b b'*, and thrown upward, after making the cut, by a spiral spring beneath.

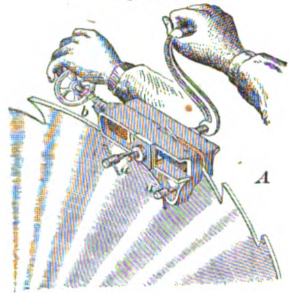
Fig. 4616.

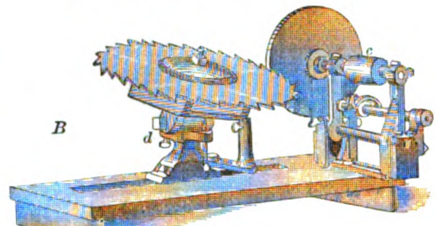


Hoe's Saw-Gummer.

In Fig. 4617, *A*, the saw is clamped between the jaws of the gummer by the screws *a a*; rapid rotation is imparted to the cutter by means of a winch, and it is advanced to deepen the cut by the hand-wheel and screw *b*. In *B*, a lap or emery wheel is turned by belt and pulley *c*; the saw is held on a stand *d*, whose distance from the lap may be varied to suit different-sized saws, and which may be tilted to vary the angle of the cutting edges of the teeth.

Fig. 4617.



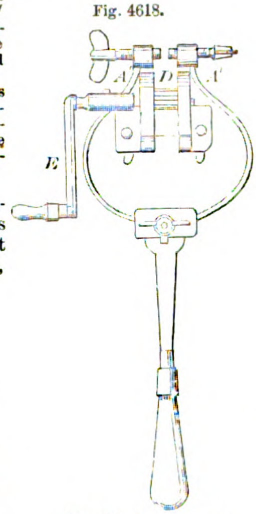


Saw-Gummer.

Fig. 4618 is a view of a portable form which is held by one hand against the blade of a mill-saw, the set-screws *A' A'* resting against opposite surfaces of the blade, while the cutting cylinder *D* is rotated by the crank-handle *E*.

There are many other forms of the tool, some of which employ the emery-wheel, commonly known as *tanite*. See EMERY-WHEEL, and specific index under GRINDING, 1017.

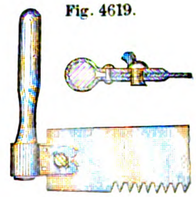
Fig. 4618.



Portable Saw-Gummer.

Saw-han'dle. Various forms of handles are used for the different kinds of saws, — hand, cross-cut, etc.

Fig. 4619.



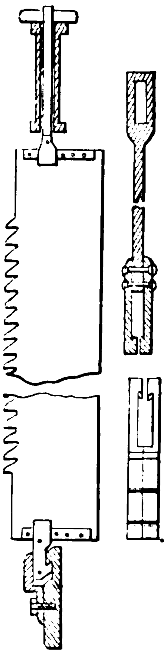
Saw-Handle.

In Fig. 4619, the wings of the handle-socket have elongated slots through which, and through a corresponding slot in the saw-blade, is passed a bolt, cam-shaped in section; this can enter the slot in only one way, and on being turned strains the blade, causing its ends to bear against the rivets, which unite the wings, while a projecting lip draws the wings together, and tends to prevent displacement.

Saw-hang'ing. The devices by which a mill-saw is strained in its gate. In the example, strips of steel are riveted on each side at each end of the saw and their dovetailed edges. Hooks with curved and correspondingly dovetailed lips engage the steel strips, and form a means of adjusting the strain at any part of the saw nearer to or farther from the edge. See also STIRRUP.

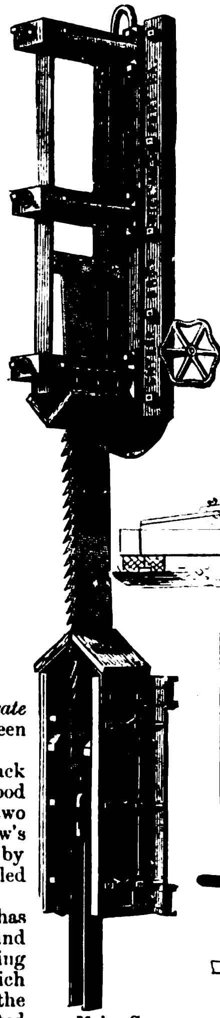
Fig. 4621 shows Snyder's muley-saw hanging.

Fig 4620.



Saw-Hanging.

Fig. 4621.



Muley-Saw.

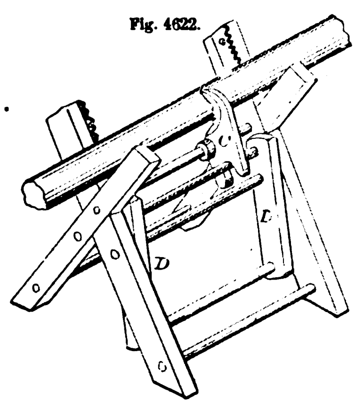
The saw is destitute of a *gate* or *sash*, but plays between guides.

Saw-horse. A kind of rack on which sticks of cord-wood are laid for sawing. Its two ends each form a St. Andrew's cross, and are connected by longitudinal stays. Also called SAW-BUCK.

That shown in Fig. 4622 has a curved clamp *C* pivoted and sliding on the upper connecting round of the frames, and which is held to or released from the log by turning the pivoted frame or lever *D D*.

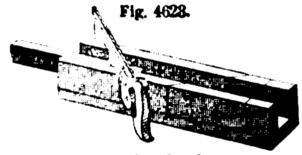
Saw'ing-block. (*Joinery.*) A wooden trough, through the upright sides of which a saw kerf is cut at right angles with the axis, and two others forming opposite angles of 45° therewith. These serve respectively as guides for cutting off square the ends of a piece of wood placed within the box, and for making miter-joints. See MITER-BOX.

Fig. 4622.



Saw-Horse.

Fig. 4623.

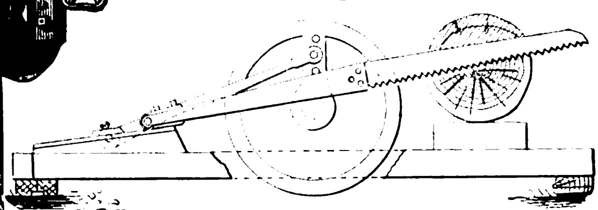


Sawing-Block.

Saw'ing-ma-chine'. A mechanical contrivance by which the power — of the man or an engine — is applied to the work of driving the saw.

The applications of the saw in shops are very numerous, and are considered under their various heads. Among them may be here cited : —

Fig. 4624.



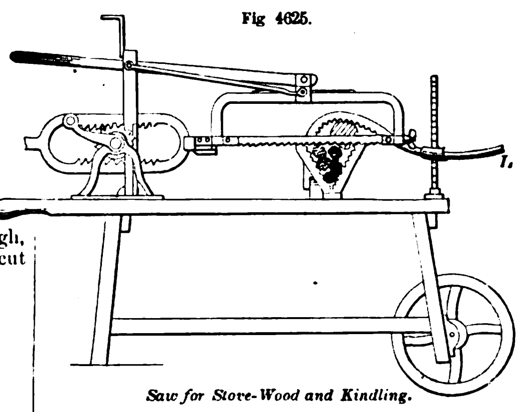
Drag-Saw for Cross-cutting Logs.

Band-saw.	Gate-saw.
Barrel-saw.	Gig-saw.
Buzz-saw.	Resawing-machine.
Circular saw.	Shingle-saw.
Drag-saw.	Stave-saw.
Gang-saw.	Veneer-saw, etc.

See also specific index under SAW, page 2035.

Fig. 4625 is a domestic saw for making short fire-wood ; the pieces are laid in a V-shaped trough,

Fig 4625.



Saw for Stove-Wood and Kindling.

held by the notched lever *L*, and the saw is reciprocated by the double rack, the teeth of the upper and lower portion being alternately thrown into gear with the pinion by automatic devices.

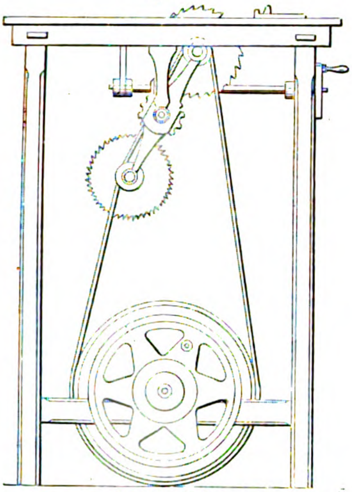
A handy workshop-form of the circular saw. In the form shown (Fig. 4626), either of several saws is brought into cutting position at the slit in the table.

Saw'ing-ma-chine' Gage. See SAW-GAGE.

Saw-man'drel. A hold-fast for a circular saw in a lathe. See SAW-ARBOR.

Saw-mill. Wood-saw mills, driven by water, were erected as early as the fourth century in Germany, on the river Roer. Stone, marble, and grain

Fig. 4626.



Sawing-Table.

mills had been used many centuries previously in Pontus, Caria, and in Rome.

Saw-mills were driven by water at Augsburg in 1322. Indeed, a saw-mill with a complete self-action and driven by a water-wheel is found in a MS. of the thirteenth century, now in Paris.

Saw-mills were erected by the Spaniards in the island of Madeira in 1420. Erected in Breslau, 1427; in Norway, 1520; in Rome, 1556.

Saw-mills driven by water afterward became common in Europe. In the year 1555, the Bishop of Ely, ambassador from Mary Queen of England to the court of Rome, visited a saw-mill in the vicinity of Lyons, which he thus describes: —

"The saw-mill is driven with an upright wheel, and the water that maketh it go is gathered whole into a narrow trough, which delivereth the same water to the wheels. This wheel hath a piece of timber put to the axle-tree end, like the handle of a broch, and fastened to the end of the saw, which, being turned with the force of the water, hoisteth up and down the saw, that it continually eateth in, and the handle of the same is kept in a rigall of wood from swerving. Also the timber lieth, as it were, upon a ladder, which is brought by little and little to the saw with another vice."

In 1575, a mill having a gang of saws, capable of sawing several boards at once, was in operation on the Danube, near Ratisbon. In 1596, the first, it is said, in Holland was erected at Saardam. In England, one erected in 1663 by a Dutchman was abandoned on account of the opposition of the populace; and more than a century later (1767), when James Stansfield established a wind saw-mill at Limehouse, East London, it was destroyed by a mob. A similar mill had previously been in operation for some years at Leith, Scotland.

In 1802, Oliver Evans of Philadelphia constructed a double-acting high-pressure engine for a boat to run between New Orleans and Natchez. On reaching the Mississippi, the boat was high and dry, and could not be floated till the periodical rise of the river occurred. The engine was, therefore, set up in a saw-mill, and sawed at the rate of 3,000 feet of boards per day. This mill, also, was burned by hand-sawyers, who thought their craft was in danger.

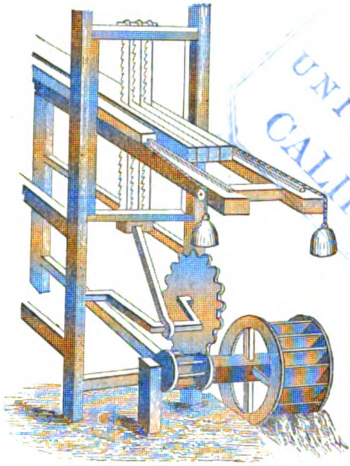
The illustration (Fig. 4627) is taken from a tract published in London in 1650, entitled "Virginia's Discovery of Silk Worms, with their Benefit and the implanting of Mulberry Trees. Also the dressing and keeping of Vines for the rich Trade of making Wines there. Together with the making of the Saw Mill, very useful in Virginia for cutting of Timber and making Clapboards to build withall, and its Conversion to other as profitable Uses."

In Michigan and Wisconsin, Canada, Maine, and Pennsylvania, the lumber business is carried on upon a large scale. An instance may be given.

Perley and Pattee's saw-mill is one of nine situated at the Chaudière Falls of the Ottawa River, just above the city of Ottawa, the capital of the Dominion of Canada. Five of these mills are on the south side of the river and four on the north side. One, Wright and Batson's, is driven by steam.

The united production of the nine mills is about 1,500,000 feet, board measure, in twenty-four hours, running day and

Fig. 4627.



Virginian Saw-Mill (1650).

night for six months in the year. A general idea of the arrangement of one of these mills may be obtained by a description of that belonging to Messrs. Perley and Pattee, above referred to.

It is a composite stone and frame building, the main part of which is 84×112 feet, with an L 48×121 feet, and two wings, 20×122 and 20×40, respectively.

Beneath the main floor is the heavy sub-frame in which the water-wheels and their adjuncts are secured, and arranged upon the floor are two *sets* of machines.

It may be here mentioned that each of these gangs is driven by a reaction water-wheel, known technically as the *Rowe reaction-wheel*, the same being 5 feet in diameter and having an area of discharge of something over 400 square inches. The head of water is 14 feet, and the quantity unlimited. The power upon each wheel is computed to be equal to 70 horses.

The *edgers* and *butters* are driven by a direct-action central-discharge wheel. The volume of water passing to each wheel is graduated by a wicket in the chute.

The logs are obtained in the Ottawa Country at various points as far as 200 miles above the falls. At the various rapids log-slides have been made, toward which the logs are directed. The saw-mill owners have combined to improve this water-way for logs, and have expended $ 130,000 in the slides, booms, piers, and other improvements.

Perley and Pattee employ about 700 men in the *bush* (as the forest is called in Canada) and 300 spans of horses.

The logs are marked, floated down the river to a point about 30 miles above the city, are then sorted for the mills on the north and south sides of the river, respectively, and at a point above the Chaudière Falls are sorted to the separate owners and collected in the ponds, whence they pass by races to the respective mills. The ponds are formed by booms or more permanent structures. The water runs from the icy north, and never slacks except in winter. The amount "running to waste" is immense, but there is no more land around the falls to set mills upon.

About 300 men are employed in the mill-yard and in shipping.

As a precaution against fire, a large "Holley" pump is rigged in a fire-proof building in the vicinity. It is driven by an 80-horse-power water-wheel, called into action should occasion require. It delivers four $1\frac{1}{2}$-inch streams through four hose.

The capacity of the mill is from 250,000 to 300,000 feet, board measure, per 24 hours, running day and night for 6 months of the year. The mill contains two *sets* of machinery. A set consists of a *slabbing-gang*, *stock-gang*, and *Yankee-gang*, succeeded by a *double-edger* and *double-butter*. The *slabbing-gang* and *stock-gang* act consecutively upon logs over 21 inches in diameter. The *Yankee-gang* is similar to the two former, but the respective gangs are in more immediate proximity, for the sake of compactness and convenience.

The logs are drawn from the fore-bay by grapples attached to an endless chain. Being placed on the ways, each is dogged between a head and tail block on an endless chain, which advances it to the slabbing-gang. Thus they pass continuously, there being no *gigging-back*. The saws are arranged to leave a central balk of a width equal to the width of the boards to be sawed therefrom in the succeeding operation (the stock-gang). The sides of the log are ripped into boards by the slab-saws, the result being a central balk and two sets of slab-boards with wany edges. This is delivered behind the gang of saws, and another log advances to the saws.

The balk is then transferred to the *stock-gang*, lying upon one of its flat sides, and is ripped into boards by the gang of saws.

The work on the *Yankee-gang* is similar, but, the logs being lighter, the gangs and ways are placed nearer to each other.

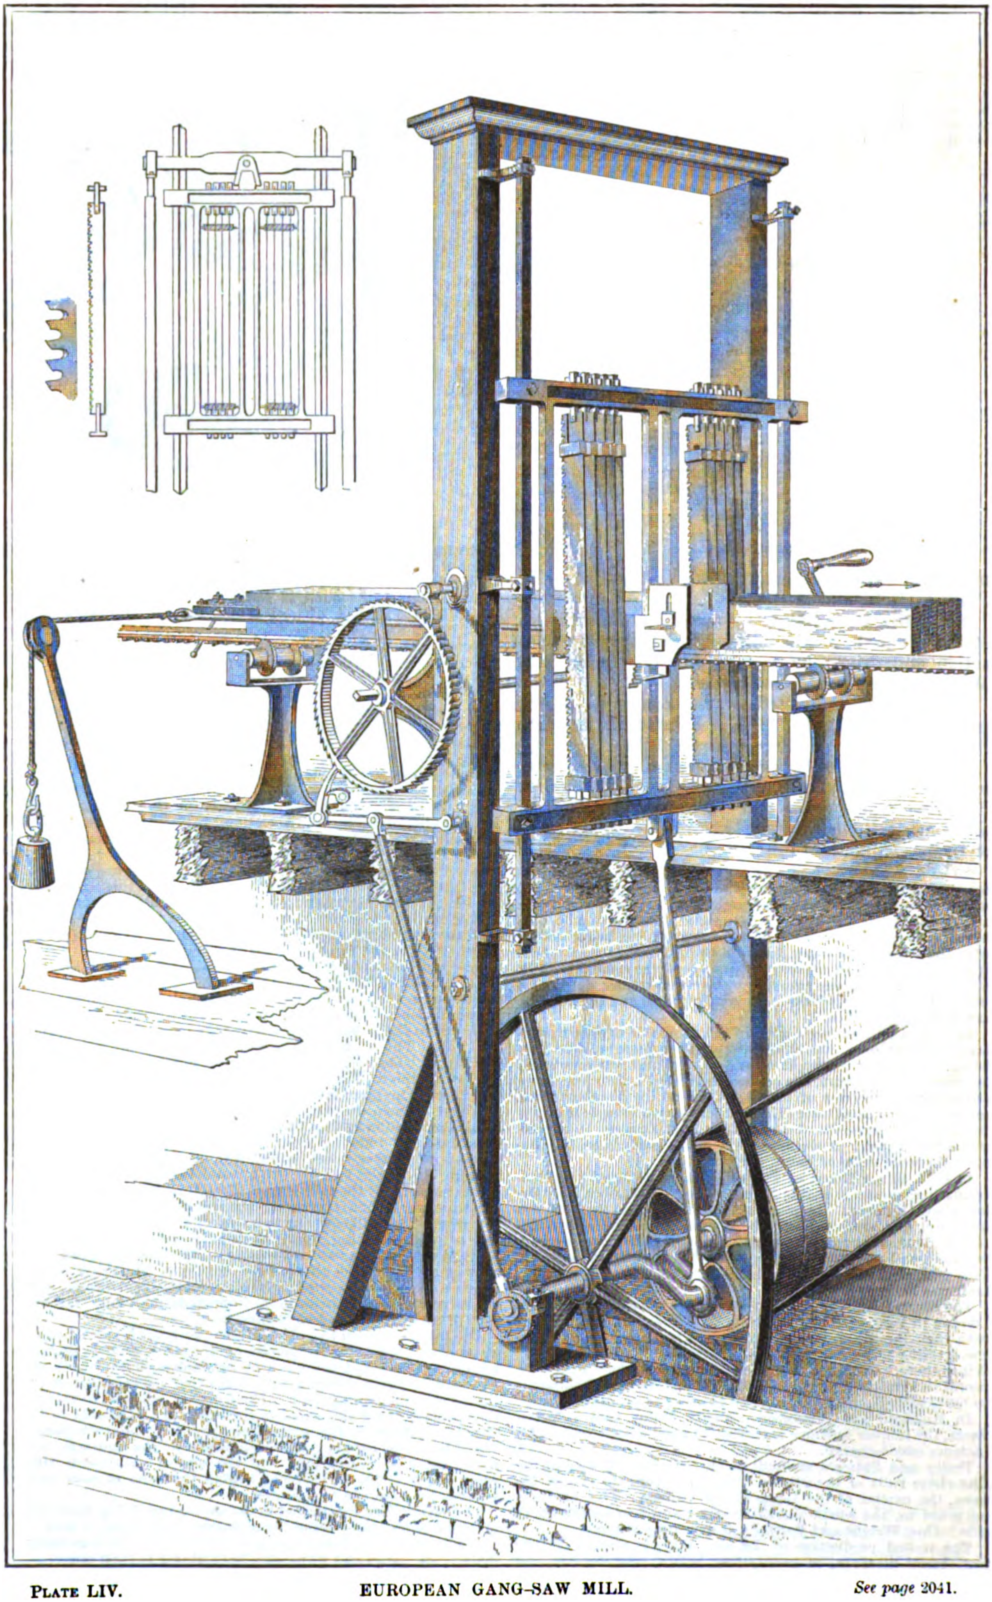


PLATE LIV. EUROPEAN GANG-SAW MILL. *See page* 2041.

The slab boards or wany stuff from the sides of the log are then taken to the double-edging machine, which has two saws, one being permanent and the other adjustable on its mandrel by means of a lever, the saw moving on a spline in the usual manner. This adjustability is for the purpose of edging boards of varying width. The boards are then lifted on to a double-butting machine, which squares the ends and brings them to a uniform length, 12, 14, 16, etc., as the case may be. Logs are cut 13 feet long for 12-feet lumber, and the mill works for a while on 16-feet and then on 12-feet stuff.

The double-butting machine has a pair of endless chains traveling in parallel planes, and having dogs at equal and coincident distances. The board is advanced by them to the two saws, and the ends are butted simultaneously.

The slabbing-saws are of No. 9 gage, and 5, 6½, or 7 feet long.

The stock-saws are No. 11 gage, and 4½ feet long.

The gage is the Stub's wire-gage.

Four hundred saws are used or in reserve, and eight men are employed in gumming, swaging the points, and filing.

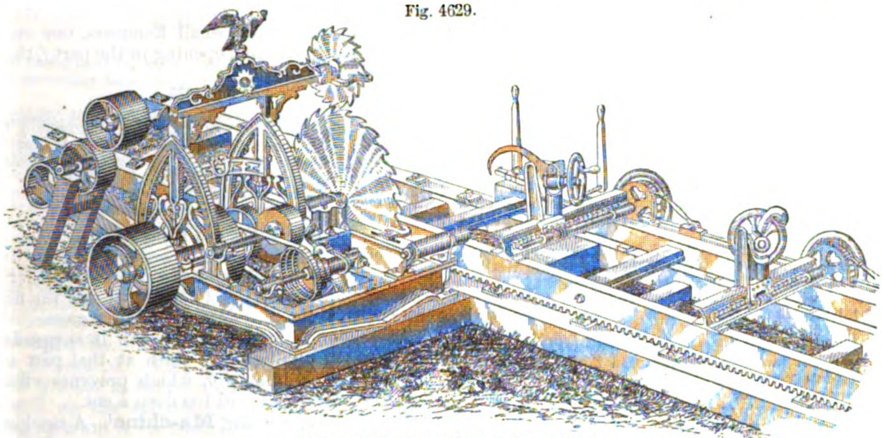
The edges of the slabs are worked into sash, blind, and door stuff, and the refuse ground up in a machine to chips, which are passed with the sawdust into the river. The authorities do not allow larger stuff to be thrown into the river, as it tends to obstruct navigation. In some mills, the pieces obtained by butting the boards are sold to be worked into matches.

The Basin Mill at Orono, Maine, is 440 feet long, 66 feet wide, has 4 gang-saws, 5 single saws, 2 circular saws, 5 lath-machines, 1 shingle and 1 clapboard machine. It saws daily 200,000 feet of long lumber, 200,000 laths, 10,000 shingles, and 4,000 clapboards, and by requirement of law burns up about 120 cords of waste wood each day.

Plate LIV. represents a European gang-saw mill.

For many centuries none but the reciprocating saws were used, and it was only during the latter half of the last century that the circular saw was used for its present purpose. This guarded expression is adopted because circular saws or disks have been used for many centuries in lathes and lapidary work. Miller's English patent of 1777 describes the circular saw, and such were made at the commencement of the century by General Sir Samuel Bentham for the British Admiralty. At present the circular-saw mill is the favorite in the woods, where the location is to be occasionally changed to comport with the supply of logs. Circular saws of very large diameter are also used in some of the great mills on the Mississippi. See also CIRCULAR SAW.

Fig. 4629.



Lane and Bodley's Circular-Saw Mill.

Saw-mill Dog. A device for holding logs on the carriage while being sawed.

Fig. 4629 has a swivel joint to permit the point to be turned in any direction.

Fig. 4629.

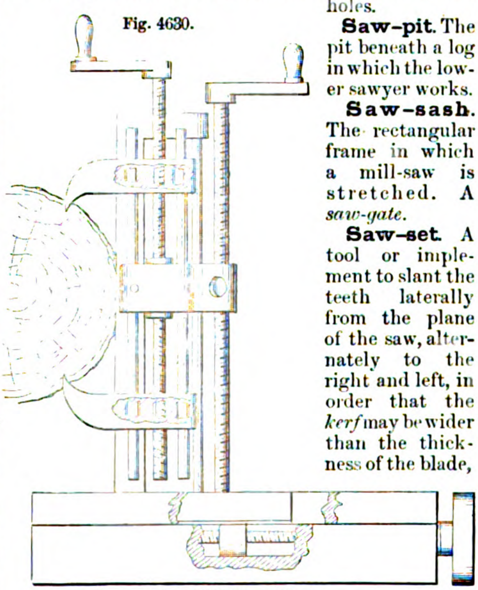
Saw-Mill Dog.

Fig. 4630 has an arrangement of two dogs that hold the log while it is being sawed, and are adjustable by means of a screw passing through the dog-heads. Two parallel rods also pass through the dog-heads to keep them firmly in position, and all turn or swing upon an upright rod passing through a swinging head, and are again adjusted by a screw-rod passing through the swinging head and bearing on the top of the head-block.

Saw-mill Gate. See SAW-GATE.

Saw-pad. A contrivance for conducting the web of a compass-saw or lock-saw in cutting out small holes.

Fig. 4630.



Saw-Mill Head-Block.

Saw-pit. The pit beneath a log in which the lower sawyer works.

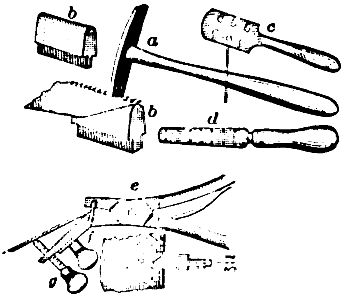
Saw-sash. The rectangular frame in which a mill-saw is stretched. A *saw-gate*.

Saw-set. A tool or implement to slant the teeth laterally from the plane of the saw, alternately to the right and left, in order that the *kerf* may be wider than the thickness of the blade, and friction be reduced. In some cases, the edge of the tooth is spread to widen its cut, instead of bending it laterally.

"Green wood fills the intervals between the teeth of the saw with sawdust, rendering its edge uniform and inert; it is for this reason that the teeth are made to project right and left in turns, so that the sawdust is discharged." — PLINY, A. D. 79.

The saw-maker generally employs a small hammer *a*, the saw being laid nearly flat, with its teeth along the ridge of a rounded edged anvil or stake *b b* held in the tail vise; the angle is in great measure determined by the curve of the stake, which is,

Fig. 4631.



Saw-Sets.

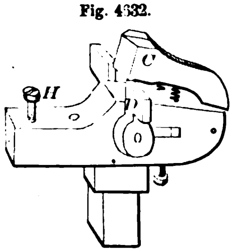
for fine-toothed saws, considerably pointed. Half the teeth having been bent, the saw is turned end for end, and the intermediate teeth similarly treated.

The set *c d* is commonly employed by the users of saws, requiring less skill to give the proper inclination to the teeth. *c* is used for large, and *d* for small saws. It consists of a narrow blade of steel, with notches of various widths, to accommodate different thicknesses of blades. The saw is held between clamps, the alternate teeth inserted a little way into the notch which they most nearly fit, and bent over to the proper angle by pressing the handle of the tool; the operation is then repeated on the intermediate teeth.

Sometimes saw-set pliers *e* are used. These require two adjustments: one for setting the jaws to the thickness of the teeth, which is effected by a stop held by the thumb-screw *f*; and the other for determining the angle to which the teeth shall be bent, which is regulated by the thumb-screw *g*.

Fig. 4632 is a form to be stuck in a hole on the work-bench. The punch *C* is pivoted to the stock, and is struck by a hammer. The gage *D*, against which the points of the teeth rest, graduates the position of the saw in accordance with the length of the teeth and in relation to the hammer. The blade rests on *H*, whose vertical adjustment determines the degree of *set*.

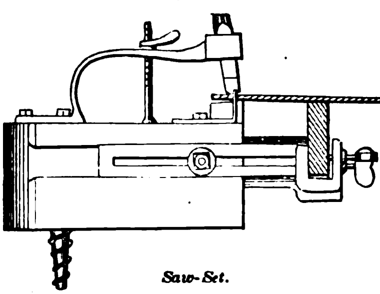
Fig. 4632.



Saw-Set.

Fig 4633 is another form of bench implement, in which the punch is placed in a socket of the adjustable spring. The saw-rest has an inclined lower side, and the brackets vary in elevation to suit, so that the rest can be moved endways to alter its elevation and the set of the saw, such movement not destroying the horizontality of the upper edge of the rest.

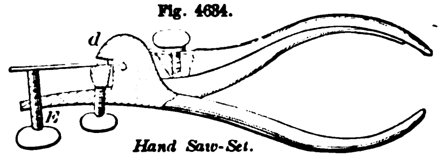
Fig. 4633.



Saw-Set.

Fig. 4634 is a hand-tool for small saws. The blades rest on *E*, and the teeth are driven by the jaw *d* upon the anvil-block.

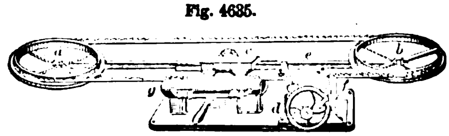
Fig. 4634.



Hand Saw-Set.

Saw Set'ting and Fil'ing Ma-chine'. The machine (Fig. 4635) for setting and filing band-saws has two flanged rotatable disks *a b* pivoted on the ends of adjustable arms passing through a clamp-piece *c*; the saw is slipped over the disks, and kept tense by extending and clamping the arms. Turning the hand-wheel *d* actuates the pawl *e*, advancing the saw the distance of one tooth at a time; the same movement causes two small hammers, one on each side of the longitudinal opening in the part *f*, through

Fig. 4635.



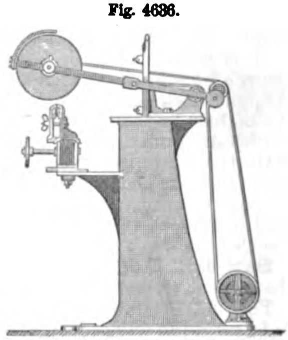
Saw Setting and Filing Machine.

which the saw passes, to strike a tooth on either side, alternately bending one to the right and the next to the left to a distance determined by a gage.

At proper intervals, the motion is suspended for the purpose of filing the teeth at that part of the saw within the clamp *g*, which prevents vibration and also serves to avoid too deep a cut.

Saw-sharp'en-ing Ma-chine'. A machine for grinding, filing, or swaging teeth of saws.

Fig. 4636.



Saw-Sharpening Machine.

In Fig. 4636, a disk of consolidated emery is employed. This is journaled on a counterbalanced arm, so as to be presented to the teeth at any required angle, and rotated by band and pulley. The saw is held by a vise with wooden jaws, clamped to the table. For sharpening circular saws, this is removed and replaced by another of different form. See also SAW-GRINDING MACHINE.

The angles at the points of saw-teeth are in general more acute in proportion to the softness of the material to be operated on, varying from 90° for metals and very hard woods to 60° or less for soft woods. To insure the action of each tooth, their points must be in the same straight line (in rectilinear saws), and for this purpose they are *topped* by laying the file, without its handle, flatwise upon their points, and reducing them to the same level by a few strokes of the tool.

More force is applied to the file in sharpening the teeth near the ends of the saw than at the middle, where they are more worn.

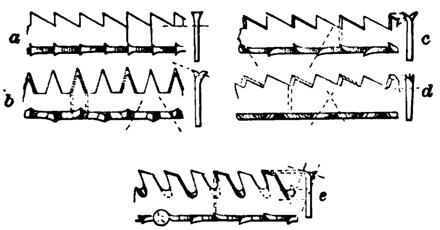
There are five different methods usually employed, depending on the character of the teeth.

The first (Fig. 4637) is applicable to the smith's frame-saw, the teeth of which have no set. The saw being held in a vise, face upward, the teeth are lightly hammered, by which they are slightly spread or upset and reduced to the same general level. The file is then applied, being held so as to form a right angle, both vertically and horizontally, with the saw-blade.

2. Peg, M, and mill-saw teeth in general, are sharpened, as shown at *b*, by applying the file to the faces of the teeth in the

direction indicated by the dotted line; several of the teeth are thus treated, operating from one side of the saw; the workman then operates from the other side, applying the file to the alternate faces, which have been left untouched, in diametrically opposite direction; this process is continued a few teeth

Fig. 4637.



Saw-Teeth.

at a time throughout the entire length of the saw, after which the two remaining faces of each tooth are filed in a similar way.

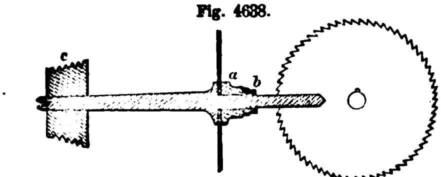
3. Hand-saw and other teeth, having angles of 60°, are sharpened by first filing the oblique faces until they coincide with one dotted line, next the backs of the same, then the other oblique faces and their backs.

4. Wood-pruning saws *d*, which are made thicker on the face than at the back, are sharpened by a triangular file applied very obliquely in a horizontal direction, sometimes at an angle exceeding 45°, as shown by the oblique lines.

5. In sharpening gullet or brier teeth *e*, the gullets are first filed with a round-edged file, somewhat smaller than the gullet, which gives a concave face to the tooth; it is then employed on the back of the preceding tooth; the top being filed last with the flat side of the file. The *setting* (see SAW-SET) is afterward performed.

Saw-spin'dle. The shaft upon which a circular saw is secured. This is ordinarily effected by means of a collar *a*, between which and the flat face of a swell on the spindle the saw is clamped by screwing up a nut *b*. A steady pin, passing through

Fig. 4638.



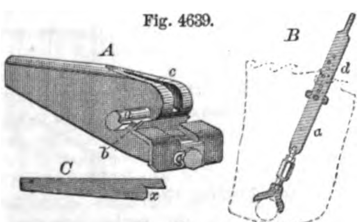
Saw-Spindle.

the saw and into the spindle, prevents slip and vibration. Rotation is imparted by a cone-pulley having a series of grooves for receiving a circular band, enabling it to be run at different velocities. See also SAW-ARBOR.

Saw-swage. A form of punch or striker by which the end of a saw-tooth is flattened to give it width and *set*.

The swage *A* has a movable rod *a* having a tooth *b* by which the points of the saw-teeth are spread

Fig. 4639.



Saw-Swages.

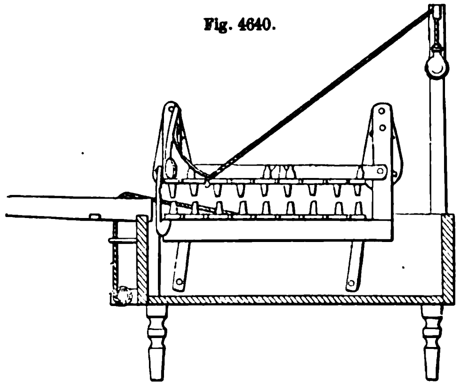
out previous to filing; for swaging and filing they are inserted within the notch *c*.

B. The split end of the adjustable bar *a* is placed on the saw-collar; the ends of the teeth are successively inserted in the notched piece *d* and swaged by a tap with the hammer.

C. The saw-tooth is inserted in the opening *x* and slightly raised by a blow; it is afterward filed to the proper hight.

Saw-tem'per-ing Ma-chine'. One for holding a saw-blade to prevent buckling when plunged into the bath. The studded and perforated plates

Fig. 4640.

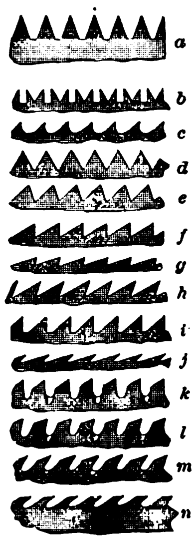


Saw-Plate Tempering-Machine.

are adjustable in distance from each other, and the studs impinge upon the opposite sides of the plate, while the same is lowered into the bath in a horizontal position to insure all parts entering the oil at the same time. See TEMPERING.

Saw-tooth. Saw-teeth are generally cut out by the fly-press. Those of the forms *d* to *h* (Fig. 4641) require but one punch, the sides of which meet at an angle of 60°. Two studs are used to direct the edge of the saw-blade to the punch, the required angle depending on the pitch or inclination of the teeth; and an adjustable stop determines the *space* or interval from tooth to tooth by catching against the side of the last tooth previously made. Gullet-teeth and the other kinds shown require punches corresponding to their peculiar shapes and sizes.

Fig. 4641.



Teeth of Saws.

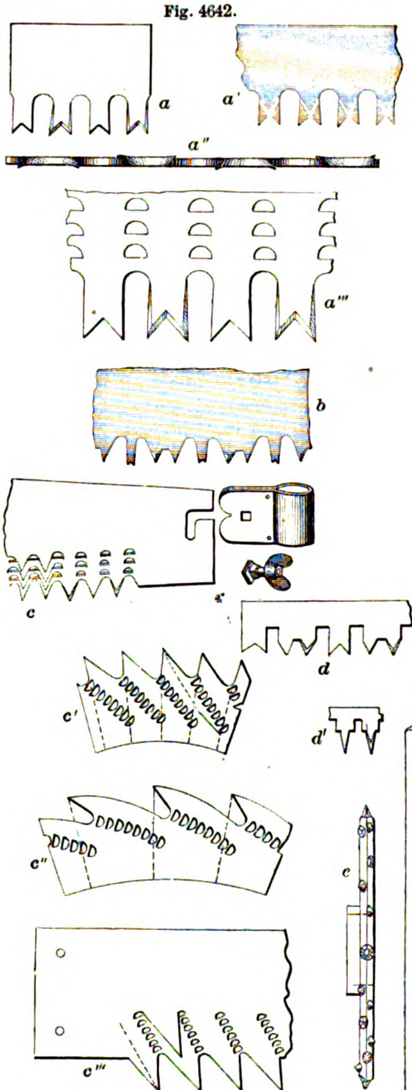
After the formation of the teeth, the blade is ground upon a grindstone of considerable diameter, and (in the case of straight saws) principally cross-ways, so that it may be thicker at front than at back.

When, by means of hammering, the blade has acquired a uniform elasticity, the teeth are sharpened with a file and *set*, that is, bent to the right and left alternately.

The word *pitch* (preferably *rake*) is employed to designate the inclination of the face of the tooth, and not the distance from tooth to tooth, as in gearing. The distance between the teeth is expressed in narrow-spaced saws by the number of *points to the inch;* when the distance between them is ½ inch or more, the saw is said to be of ½-inch, ⅝-inch, etc., *space*.

Fig. 4641 shows various forms of saw-teeth: —
a, peg-tooth or fleam-tooth.
b, M-tooth.
c, half-moon tooth.
d, cross-cutting tooth.
e, *slight pitch* or cross-cutting tooth, generally used in small saws; the pitch exceeds that of the former by about 15°.
f, hand-saw, or *ordinary pitch* tooth
g, tooth having the cutting-face *set forward* at an angle of 15°, used in mill-saws for soft wood.
h, tooth used in some circular saws; also occasionally for pit-saws, cross-cut saws, and saws for cutting soft stone.
i, shouldered tooth, employed in some rectilinear saws.
j, a similar tooth, having greater pitch; used in circular saws.
k l m n, gullet or brier teeth: the first is better adapted for cross-cutting and for hard woods, such as mahogany; the two next for pit and mill saws; and the last for ripping and for soft woods.

Fig. 4642.



Saw-Teeth.

In Boynton's saw (*a a' a''*, Fig. 4642), the teeth are all clearers, as well as cutters; the cutting-edges of the teeth are alternately on each side of the blade, and they are set alternately to the right and left.
a''' is Boynton's perforated saw.
Hoe's cross-cut saw *b* has double cutting-teeth, their cutting-edges alternating, and slender clearing-teeth interposed between each pair of cutters, as shown in the figure.

Emerson's saws (*c c' c'' c'''*, Fig. 4642) have series of semi-circular openings in the blade, back of the gums. These serve to prevent a crack between the teeth from extending farther in case it should occur, and also obviate the necessity of removing much metal with the file in the process of gumming.

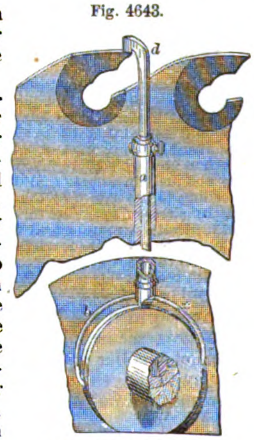
Lippincott's cross-cut saw *d d'* has slots or indentations having parallel sides, and extending into the blade below the root or termination of the inclined side of the teeth, for the purpose of serving as a guide in dressing the saw with a file, so as to preserve the original shape and relative distance apart of the saw-teeth, and enable it to be kept in order without gumming.

Drake's stone-cutting saw *e* has diamond points, constituting or affixed to the teeth. The illustration shows an elevation of a circular saw on this plan. See STONE-SAW.

For insertable-teeth saws, see Fig. 4596; for varieties of teeth, see Fig. 4641.

Saw-tooth In'di-ca'tor. A device for insuring the filing or setting the teeth of circular saws to an equal distance from the center. It consists of a hollow shaft *a*, having a V-shaped point and two curved arms *b c*, which are adjusted to a groove in the saw-collar. The movable branch *d*, whose outer end has a knife-edge, is set to the proper distance from the center, and held in this position by a screw.

Fig. 4643.

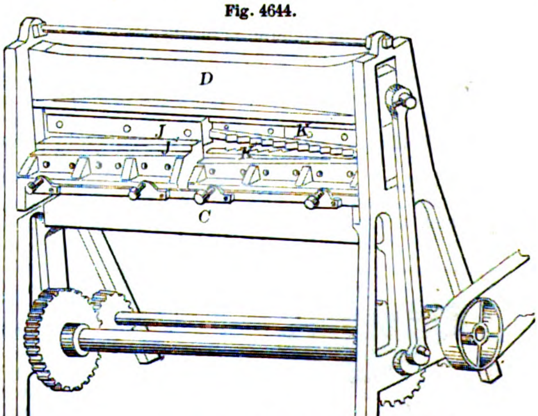


Saw-Tooth Indicator.

The points of the teeth, if projecting beyond this distance, are filed down, or if they are too low and movable, they may be adjusted to proper hight by filing away the shoulder.

Saw-tooth'ing Ma-chine'. The machine (Fig. 4644) has a gate *D* reciprocated by an eccentric and

Fig. 4644.

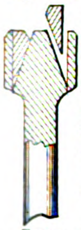


Saw-Toothing Machine.

pitman, and has at one end two plain shearing-blades *J J'*, and at the other two toothing-blades *K K'*, secured to blocks attached to the gate and frame *C*, respectively. Two saws are cut from a sin-

gle sheet at each operation, the projecting teeth of one corresponding to the interspaces of the other. The blades have a slight inclination, so that the cutting action is gradually effected. Adjustable gages are secured to the shearing and toothing ends of the gate, traveling down along with the cut plate or saw, and on the return stroke the work is released and sticking prevented.

Fig. 4645.



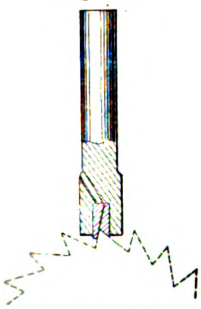
Swage for Saw-Teeth.

Saw-tooth Swage. An anvil block used in connection with a punch or wedge of some kind to flatten the edge of a saw-tooth. See also SAW-SWAGE.

Saw-tooth Up-set'ter. A tool to spread the edge of a saw-tooth. In Fig. 4646, two steel wedges are socketed in a stock, their faces adapted to form the edges of the tooth; the tool is driven upon the tooth, upsetting and displaying it to widen its kerf. See SAW-SWAGE.

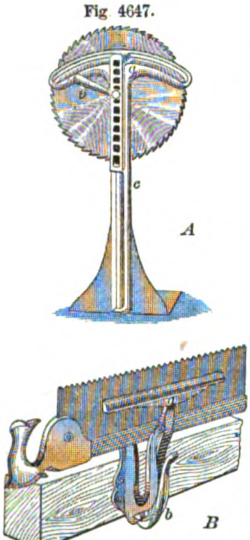
Saw-vise. A species of clamp for holding saws while filing. *A* has two jaws, one of which is seen at *a*; they are of metal lined with wood, and are closed or unclosed by turning the handle *b*. The temporary mandrel of the saw may be placed in either of the holes of

Fig. 4646.



Tool for Upsetting Saw-Teeth.

Fig. 4647.



Saw-Vises.

the perforated standard, according to the diameter of the saw, so that its periphery or edge shall be in the required proximity to the jaws of the vise.

B is secured by screws to any convenient support, and the upper part of one leg carries a fixed jaw. A movable jaw *a* is pivoted in the other leg, the lower end of its shank being in contact with a cam-lever *b*. Depressing the lever closes this jaw, which is thrown outward by a spring when the lever is depressed.

Saw-wrest. A tool to bend saw-teeth to give them a *set*. See SAW-SET.

Saw'yer's-dog. A *timber*-dog, *raft*-dog, *saw-mill* dog. An iron bar with a bent-over end, which is pointed to drive into a log.

Sax. A slate-maker's axe, for trimming slates to shape. It is 16 inches long and 2 broad, and has a point at the back for making nail-holes in the slate.

Sax'horn. (*Music.*) A wind-instrument of metal with keys and valves, and made *en suite*, that is, of various sizes and compass. See HORN, *f f f*.

Sax'o-phone. (*Music.*) A brass musical instrument with a single reed and a clarinet mouthpiece. The body of the instrument is a parabolic cone of brass provided with a set of keys. They are seven in number, the *high*, *soprano*, *alto*, *tenor*, *barytone*, *bass*, and *double-bass*. The compass of each is nearly the same. See HORN, *b*.

Sax'o-trom'ba. (*Music.*) A brass instrument with a mouthpiece and three or four cylinders. It is, like the *saxhorn* and *saxophone*, made *en suite*, but, its tube being a little more contracted, it gives a shriller sound.

Sax-tu'ba. (*Music.*) An instrument with a mouthpiece and a mechanism of three cylinders.

Say. (*Fabric.*) A thin woolen cloth. The name is obsolete, but exists in old authors.

"Thou *say*, thou serge, nay thou buckram [barracan] lord."
SHAKESPEARE.

Commoner goods for each succeeding epithet.

Say-ette'. (*Fabric.*) A mixed fabric of silk and wool. *Sagathy.*

Scab'bard. The sheath of a cutting weapon or bayonet, made of metal, wood, leather, raw hide, or paper. The first mentioned is the poorest material for the purpose. So said Captain Nolan of the English Dragoons, killed in the heroic but wanton cavalry charge at Balaklava in the Crimea.

In early times men had cases for their knives; and, associated with the earliest history, the swords are seen in their scabbards, as in the sculptures of Nimroud.

Scab'bard-plane. An abbreviation of SCALE-BOARD PLANE (which see).

Scab'bled. (*Masonry.*) Stone dressed with a fine axe, in contradistinction to plain-faced. *Scappled.*

Scab'bling-ham'mer. (*Masonry.*) A mason's tool used in reducing stone to a surface. It has two somewhat pointed ends, whereby the stone is picked. The face of the stone is left in lines, and is said to be *nigged* or *nidged*. The roughly dressed block is termed a *nigged ashlar*. It succeeds in weight and order of use the *spalling-hammer* or *kevel*.

Scaf'fold. 1. (*Building.*) A platform temporarily erected during the progress of a structure, for the support of workmen and material.

The ordinary bricklayer's scaffold consists of upright poles called *standards*, supporting the horizontal poles which are lashed thereto and called *ledgers*; these support the outer ends of the *putlogs*, the other ends resting in holes in the wall. The scaffold boards rest on the putlogs.

Square timber-scaffolding with a traveling-crane was introduced into England at the building of Euston Station of the Northwestern Railway, London, and subsequently was used at the raising of the Nelson Column, Trafalgar Square, London, and the new Houses of Parliament, Westminster. See OVERHEAD-CRANE; TRAVELING-CRANE.

The square timber-scaffolding was, however, used on the Cologne Cathedral from the commencement of its building, A. D. 1248, and probably will be for several hundred years to come on the same structure, in the rebuilding and extension which seem to be progressing simultaneously.

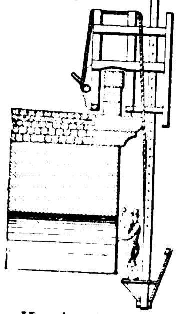
A precedent for the Nelson Column erection is found in the more complex and difficult work of raising the Egyptian Obelisk in the Plaza of St. Peter's at Rome, by Domenic Fontano, A. D. 1586.

The Arc de l'Etoile and the Eglise de la Madeleine are triumphs of the first Napoleon, on which the same style of scaffolding was used.

The tendency in the United States is to the use of the derrick-crane, whose simplicity and efficiency leave little to be desired. The extension of the Treasury Building in Washington, under the conduct of A. B. Mullet, was made by colossal stones; its monolithic character is said to be second only to the Church of St. Isaac's at St. Petersburg, Russia. The derrick-crane was used on this building, and on the Capitol Extension also.

Fig. 4648 represents a hanging scaffold contrived by Perronet for the workmen employed in dressing and pointing the masonry of the arches of the bridge at Orleans. It was suspended from a frame which straddled the parapet, and was rolled from place to

Fig 4648.



Hanging Scaffold.

place as required. The platform could be raised and lowered and held at any desired hight.

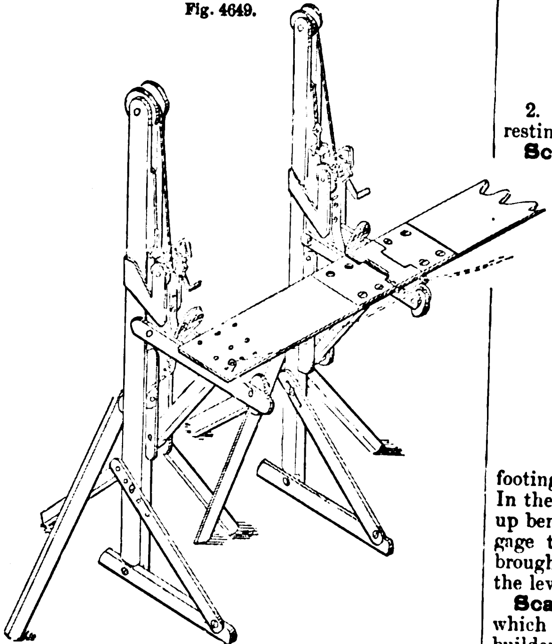
Curious turning scaffolds have been used in domes. See Cresy.

From the numerous varieties, three representative examples may be shown: —

a. Suspended from spars or upright timbers. The uprights have base supports and braces at their lower ends. The platform is connecting to sliding frames which are raised by ropes passing over sheaves at the tops of the uprights and wound by windlasses attached to the frames.

b. Propped against the building. In the example, the platform is sustained against the wall by the

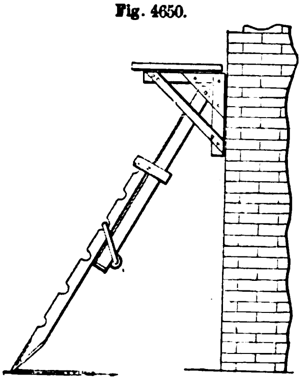
Fig. 4649.



Builders' Suspended Scaffold.

extensible props reaching from the ground to the inner angle between its horizontal and vertical parts.

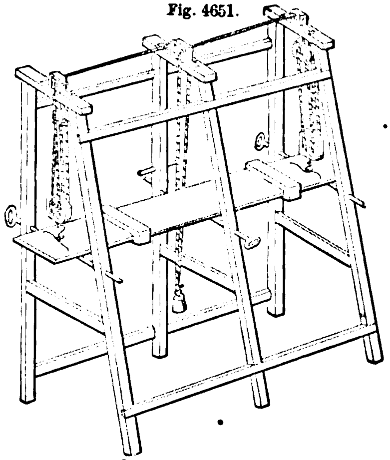
Fig. 4650.



Propped Scaffold.

c. Suspended from *trestles*. The platform is balanced by ropes passing over pulleys secured to the upper cross-pieces of the trestle-frame, the said ropes having a weight attached to one end. The platform is sustained in any fixed position by bars, which are passed through holes in the uprights of the trestle.

Fig. 4651.

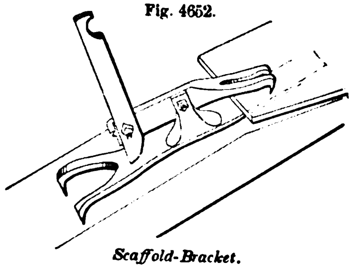


Suspended Scaffold.

2. (*Mining.*) A platform affording a temporary resting-place for an ascending or descending load.

Scaf'fold-brack'et. An implement to form a

Fig. 4652.



Scaffold-Bracket.

footing for a board to support a person in roofing. In the example, the tang of the lower plate is pushed up beneath the course of shingles, and its claws engage the rafter. The upper pivoted claw-plate is brought down upon the shingles by the vibration of the lever.

Scaf'fold-ing-pole. One of the vertical poles which support the putlogs and boards of the usual builder's scaffold.

Scagl-i-o'la. A hard, polished plaster, colored in imitation of marbles.

Scagliola is prepared from powdered gypsum mixed with isinglass, alum, and coloring matter into a paste, which is beaten on a prepared surface with fragments of marble, etc. The surface prepared for it has a rough coating of lime and hair. The colors are laid on and mixed by hand, in the manner of fresco, and in imitation of various kinds of marbles. When hardened, the surface is pumice-stoned and washed; it is polished successively by tripoli and charcoal, tripoli and oil, and oil alone.

Scald'ing. *a.* The last boiling or bucking of cloth with white soap after bleaching.

b. The soap itself.

Scale. 1. A measure divided into equal parts, usually main divisions and subdivisions; as inches and octonary fractions for carpenters' work, decimal divisions and subdivisions for chain-work, duodecimal for plotting carpenters' work which is in feet and inches. The meter and its decimal subdivisions are also sometimes employed.

Used by surveyors, architects, and draftsmen for laying down work on paper.

Among the kinds may be cited the following, but some of the names are synonyms: —

Architect's scale.
Drafting-scale.
Engineer's scale.
Gunter's scale.
Mathematical scale.
Micrometer-scale.
Offset-scale.
Pocket-scale.
Protracting-scale.
Sector-scale.
Slide-rule.
Sliding-scale.
Tailor's scale.

Some of these are considered under these heads. They are made of

Aluminium.
Beech.
Bone.
Box.
Brass.
Ebony.
German-silver.
Glass.
Horn.
Ivory.
Palladium.
Paper.
Silver.
Steel.

Scales are variously graduated, so that certain simple relations between numbers, trigonometrical lines, etc., may be ascertained by inspection. To this class belong the sector (which generally forms part of a case of mathematical instruments); Gunter's scale, and Dr. Wollaston's scale of chemical equivalents.

See list under CALCULATING AND MEASURING INSTRUMENTS.

2. A balance for weighing; in this sense the word is usually employed in the plural.

They frequently receive special names, as —

Coin-weighing machine.
Counter-scales.
Platform-scales.
Spring-balance.
Steelyard.
Weighing-machine.

Some of which are considered under their respective heads. See also BALANCE, page 213.

Weighing-machines and scales, measures, and weights have, in some form, been in use from time immemorial. Pliny states that they were invented by Phidon of Argos, or, according to Gellius, by Palamedes. Many centuries before this time, however, Abraham, 1860 B. C., *weighed* out "400 shekels of silver, current money with the merchant," to Ephron the Hittite, as payment for a piece of land, including the cave and all the standing timber in the field and the fence. This sale was made in the presence of witnesses, and is believed to be the earliest transfer of land of which record survives.

In ancient Egypt the superintendence of weights and measures belonged to the priests until the privilege was removed from them by the Romans. The scales were in the public market, and recourse was had to them by buyers and sellers. The practice still prevails to a great extent in modern Egypt. The same mode was adopted in Greece, as we read: "As the civil magistrate weighs bread in the market-place."

The scales were erected temporarily, and had the ordinary "beam suspended from a stirrup at its mid-length." The weights, like the money, were in the form of rings, as may be seen in a number of places on the Theban tombs. See COINING.

Large scales were flat wooden boards, each attached by four ropes to a ring at its respective end of a beam, which was supported by a middle ring, suspended from the standard post.

The steelyard is a Chinese invention. Wilkinson failed to find it at Thebes or Beni Hassan.

Fig. 4653.

Egyptian Scales.

It was used in Rome under the name of *statera*. See BALANCE; WEIGHING-MACHINE.

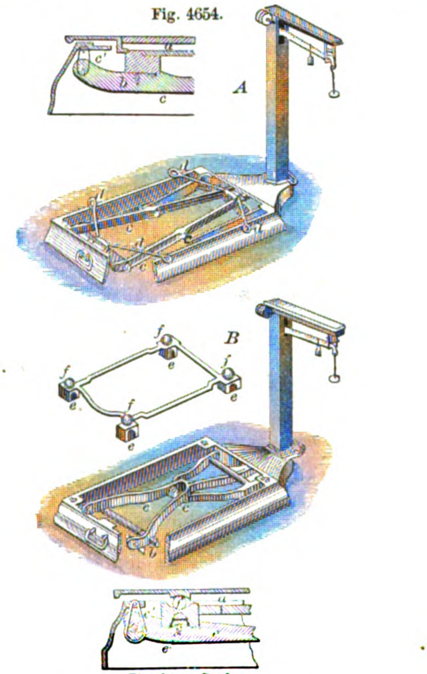
The illustration is from an ancient Egyptian papyrus in the British Museum, representing the "Ritual of the Dead" of Hennefer, superintendent of the cattle for Seti I., about 1350 B. C. The heart of the deceased is being weighed before Osiris in the Hall of Perfect Justice. It will be noticed that the balance-beam is not suspended from the middle with a series of weights, like the modern scale, nor in the manner of the *statera*, or steelyard; but it has a shifting fulcrum, by the adjustment of which the differences of the weights of the articles may be ascertained.

The *lever-scale*, on the principle of the steelyard, has for 40 years been used in the United States, for all purposes, from that of a letter-weigher to that of the weigh-lock scale. The former weighs to half-ounces, and the latter to 1,200,000 pounds. Here this principle is supreme; in England it is yet far otherwise. The ordinary balanced beam, with a number of iron weights, 112 pounds each, in one scale and the hogshead of sugar or what not in the other, was the ordinary means of weighing in the London Docks, a few years since, and may be yet.

Platform-scales were probably in use in England in 1796, one being patented in that year by Salmon.

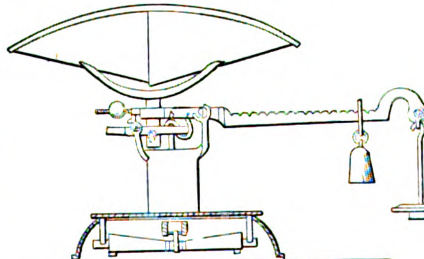
In the ordinary platform-scale (*A*, Fig. 4654), the platform *a* has a downwardly projecting steel-faced plate at each corner, which rests upon the knife-edges *b* of the levers *c*; the downward motion of the free ends of the levers is limited by loops *c'*. The platform is steadied by check-rods *d* connected to it and to the scale.

Fig. 4654.



Platform-Scales.

Fig. 4655.

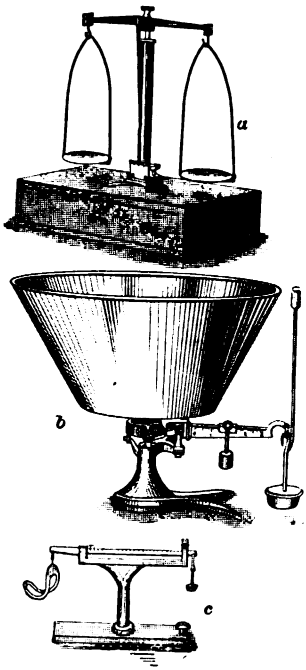


Platform and Scoop Scale.

The Howe scale *B* has adjustable bearings *e* at the corners of a framework resting upon the knife-edges *b*: balls *f* are interposed between this framework and the platform for obviating jar and friction on the knife-edges when a weight is placed on the scale and the check-rods are dispensed with. See WEIGHING-MACHINE, for the larger kinds.

Fig. 4655 is a combination of the platform and scoop scale, in which one graduated beam is connected to both the platform and scoop, so that the weight of articles placed on either is indicated on the beam, without the necessity of adjusting any part of the scale. By the proportioning of the leverages, the weight on the beam will balance much heavier articles on the platform than in the scoop.

Fig. 4656.



Counter-Scales.

Fig. 4656 shows three forms of scale for factory purposes.

a is a *yarn* scale for sizing. One *lea* or *cut* of 120 yards is used.

b is a *lap* scale to weigh quantities of cotton or wool, to be spread on the feed-apron of the carding-machine.

c is a form of scale for weighing yarn, roving, drawing slivers, etc. See also COUNTER-SCALE.

3. (*Cutlery.*) One of the side plates of iron or brass which form the main portion of a pocket-knife handle, and to which the *sides* of ivory, bone, wood, etc., are riveted.

4. A metallic plate worn instead of an epaulet by soldiers.

5. (*Metal-working.*) The film of oxide which forms on the surface of iron or other metal when heated.

6. (*Steam.*) The hard deposit which gathers in steam-boilers. See INCRUSTATION, page 1177.

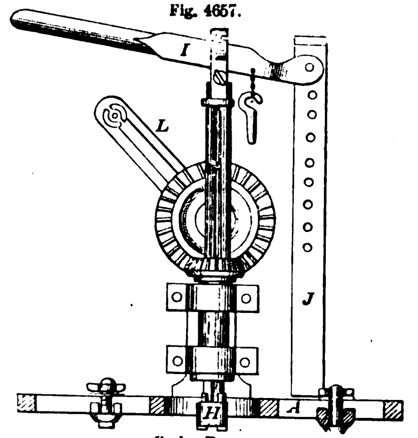
Scale′board. 1. A thin veneer of wood, used for covering the surfaces of wooden articles of furniture; as backing for pictures and looking-glasses, for making wooden boxes, and for very many other purposes.

2. (*Printing.*) A thin slip of wood, used for extending pages of type to the proper length, filling out matter, etc. See REGLET.

Scale′board-plane. (*Joinery.*) One for planing off wide chips, for fruit, hat, and bonnet boxes and other objects. It is a plane the width of a board, is loaded with weights, and dragged or driven over the surface of the board or balk, the degree of protrusion of the plane-iron determining the thickness of the *scale*. A converse arrangement is that in which the plane is fixed and the board is driven past it.

Scale-bor′er. An implement for removing the scale from boiler-tubes. Keener's (Fig. 4657) is arranged to be readily taken apart, so that it may be introduced through the man-hole. The bed-plate *A* is secured to the boiler-sheet by screw-clamps; the cutter-head *H* on the shaft *G* is rotated by bevel-gears through the medium of the crank *L*, and is advanced by the lever *I* adjustably fulcrumed in the standard *J*. Extensions may be fitted to the

Fig. 4657.



Scaler-Borer.

shaft *G*, enabling it to bore through tubes of any length.

Scale-mi-crom′e-ter. A graduated scale in the field of a telescope for measuring distances between objects. A *linear micrometer*.

Scale-pi-pette′. A tubular pipette having a graduated scale on the side, enabling various definite quantities of liquid to be taken up. The *bulb-pipette* has a swelled bulb and but a single mark.

Scal′er. A dental tool for removing salivary calculus (*tartar*) from the teeth. They have various shapes, — as chisels, scrapers, gouges, with straight, oblique, curved edges, to enable them to penetrate to deep-seated parts.

Scal′ing. 1. (*Metal-working.*) A preliminary process in the manufacture of tin plate. The rectangular plates are bent so as to stand when placed on edge, pickled in dilute muriatic acid, heated in a furnace to remove the scale, cooled, flattened on an anvil, and rolled cold. See TIN PLATE.

2. (*Nautical.*) The process of adjusting sights to the guns on shipboard was formerly so termed.

Scal′ing-bar. (*Steam.*) A rod for detaching scale in boilers.

Scal′ing-fur′nace. (*Metal-working.*) A reverberatory furnace in which plates are exposed in the process of scaling.

Scal′ing-ham′mer. (*Steam.*) A hammer with an edge peen, used in loosening scale formed in steam-boilers.

Scal′ing-lad′der. A ladder used in the assault of fortified places.

The parties represented as attacking fortified cities, in the paintings of ancient Egypt, are provided with scaling-ladders. One shown in the Memnonium has 34 steps; it was probably 48 feet long.

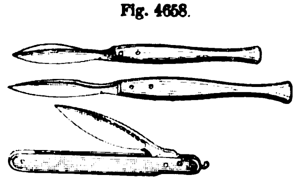
It has played a much less important part in sieges since the introduction of artillery; the use of which is continued when practicable until the rubbish detached and broken up by its fire has formed a slope, over which the storming parties may pass. Its principal modern use is to facilitate the descent into the ditch, as the counterscarp cannot be demolished by the artillery.

Scal′lop-ing-tool. (*Saddlery.*) A tool for giving an ornamental edge to leather straps.

Scal′pel. (*Surgical.*) A knife used in operations and dissections.

Fig. 4568 shows

Fig. 4658.



Scalpels.

two forms in fixed handles, and one in a sheath like a lancet.

Scalp'er. (*Surgical.*) A tool for rasping bones. A *scalping-iron.*

Scalp'ing-ir'on. (*Surgical.*) See SCALPER.

Scalp'rum. (*Surgical.*) A rasping instrument used in trepanning; or removing the roughness from the edges of bones, or the teeth.

Sca-mil'lus. (*Architecture.*) A small plinth below the bases of Ionic and Corinthian columns.

Scam-pa'vi-a. (*Vessel.*) A fast-rowing war-boat of Naples and Sicily; in 1814–15 they ranged to 150 feet, pulled by 40 sweeps or oars, each man having his bunk under his sweep. They were rigged with one huge lateen at one third from the stem; no forward bulwark or stem above deck; a long brass 6-pounder gun worked before the mast; only 2 feet above water; abaft a lateen mizzen with topsail. — ADMIRAL SMYTH.

Scant'ling. 1. (*Carpentry.*) Lumber under 5 inches square, used for studs, braces, ties, etc. It is expressed in terms of its transverse dimensions; as "a timber having a scantling of 12 × 8."

2. (*Masonry.*) The dimensions of ashlar stones.

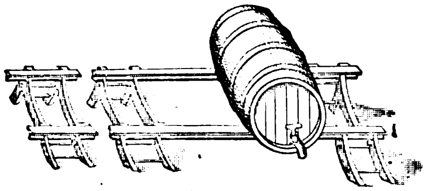
3. (*Shipbuilding.*) The transverse dimension of pieces of timber, etc. The respective sides are known as *molding* and *siding.*

Molding is depth or dimension which lies in the molding-plane.

Siding, the thickness in a direction perpendicular to the molding-plane.

4. A trestle or horse in a cellar for holding casks on tap.

Fig. 4659.



Scantling for Casks.

5. The rough draft of a work or plan.

Scape. (*Architecture.*) *a.* The shaft of a column.

b. The apophygee of a shaft.

Scape'ment. (*Horology.*) See ESCAPEMENT.

Scape-wheel. (*Horology.*) The wheel in an escapement whose teeth escape one at a time from the pallets.

Scap'ple. (*Masonry.*) To reduce a stone to a comparatively level surface by hammer-dressing without smoothing.

Scap'pling-ham'mer. (*Stone-working.*) A hammer for dressing the face of a stone.

Sca'pus. (*Architecture.*) See SCAPE.

Scarce'ment. 1. (*Mining.*) A ledge of a stratum left projecting into a mine-shaft as a footing for a ladder. A support for a pit-cistern, etc. It is so fashioned below as to form a corbel or bracket.

2. (*Building.*) A ledge or footing formed by the setting back of a wall.

Scarf. 1. (*Carpentry.*) A joint uniting two pieces of timber endwise. The ends of each are beveled off, and projections are sometimes made in the one corresponding to concavities in the other, or a corresponding cavity in each receives a joggle; the two are held together by bolts, and sometimes also by straps. Also written *scarph.*

The rods for the pumps of mines are sometimes made in wooden sections joined together by scarfs and bands. *a,* Fig. 4660, is from a pump-rod in a German mine.

It is common, but not universal, to scarf the timbers together without making a bulge at the junction. In some cases the parts are simply laid or driven together, and in others they are forced to their seats by means of a wedge. In all cases the notches of one have counterpart projections on the other face, and the surfaces fit snugly against each other without longitudinal or lateral play.

The mode of scarfing which has the appearance of a regular zigzag, when viewed in elevation, is called by the French, *traits de Jupiter* (*i*), from a fancied resemblance to forked lightning.

The timbers are secured by bolts, straps, side plates, stirrups, or other devices, according to circumstances and the nature of the strain

Fig. 4660 illustrates various modes of scarfing

a, pump-rod scarf

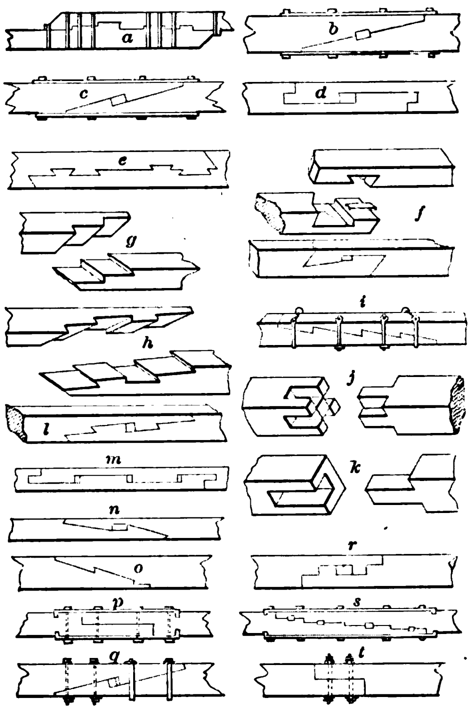
b c, scarfs with wedges and fish-plates.

d, scarf with wedge

e, scarf without wedge.

f, another form showing the two pieces apart and united.

Fig. 4660.



Scarfs.

g h, different ways of making the joint.

i, traits de Jupiter.

j k, end scarfs

l m n, square and bevel scarfs.

o, hook and butt.

p, square scarf with iron fish-plate.

q, bevel scarf with bolts.

r, hook butt scarf

s, scarf joint secured by fish-plates, bolts, and keys.

t, plain rabbeted scarf with bolts.

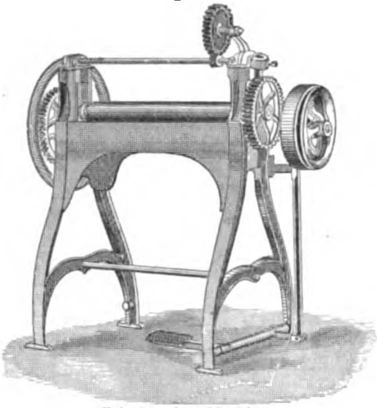
2. (*Metal-working.*) The flattened or *chamfered* edges of iron prepared for welding. The two surfaces being drawn out or cut obliquely, a larger contact is given to them, which fortifies the junction.

Scarf-bolt. (*Shipwrighting.*) One used by shipbuilders for securing the false keel.

Scarf'ing-ma-chine'. A machine for tapering or shaving the ends of leathern belts where they lap to form a joint. It has an upper or "hand-wheel shaft," having right and left screws at its ends, playing in wedges which act upon the vertically sliding

boxes of the upper or gage roller, so that the leather, which is fed with a drawing motion against the

Fig. 4661.



Belt-Scarfing Machine.

knife, may be tapered or scarfed to an edge, — *feather-edged.*

Scarf-joint. See SCARF.

Scarf-loom. A narrow-ware figure-loom of such width and capacity for variety of work as to adapt it for ornamental weaving of fabrics of moderate breadth.

Scar'i-fi-ca'tor. (*Surgery.*) *a.* An instrument used in dental surgery in separating the gum from the teeth.

Fig. 4662.

Scarificator.

b. An instrument used in cupping. It has a number of lancets, whose protrusion beyond the face of the case is adjustable. These are set in a retracted position, and simultaneously discharged by a pull on the trigger, so as to protrude through the apertures in the plane face and make a number of incisions through the skin.

c. A lancet for scarifying the skin or an engorged membrane.

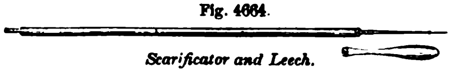
Dr. Buttle's uterine scarificator and leech (Fig. 4664) is used for abstracting blood from the engorged

Fig. 4663.

Desmarre's Scarificator.

cervix-uteri. The handle portion, shown detached, acts as a cover for the needle when in the pocket. In use, the elastic-bulb handle is attached to the

Fig. 4664.



Scarificator and Leech.

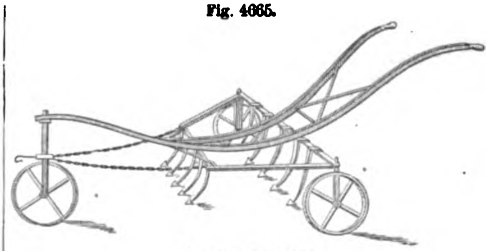
hilt end of the instrument, and, being compressed, affords a means of withdrawing blood through the hollow needle and stock.

Scar'i-fi'er. 1. (*Surgical.*) An instrument for lancing preparatory to cupping. A *scarificator.*

2. (*Agriculture.*) An agricultural implement used in Britain for stirring the soil. It is a wheeled cultivator, but the teeth are long, sharp, and comparatively thin. Its construction will be readily understood from the illustration.

Fig. 4666 has a series of cutting-disks, like colter-wheels, pivoted in standards attached to the inclined

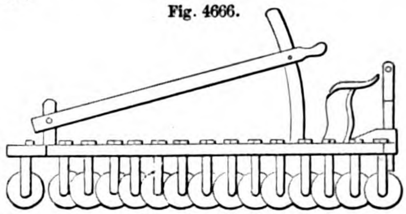
Fig. 4665.



Henry's Scarifier.

bars of a frame which is vertically adjustable upon rollers.

Fig. 4666.



Wheel-Scarificator.

Scarp. (*Fortification.*) The interior slope or wall of the ditch at the foot of the *parapet.* It is hidden from the enemy by the *glacis.* See PARAPET; ESCARP.

The scarp and counterscarp were used by the early Egyptians, and also the parallel wall in the ditch. They were originally contrived against the movable towers of assailants; but favorable banks or recesses in the ground must always have been welcome to those who fought with missiles.

Scatch. (Fr. *escache.*) (*Menage.*) A kind of bridle-bit.

Scav'en-ger-roll. (*Cotton Manufacture.*) A roller in a spinning-machine to collect loose fiber and fluff which may gather on the parts with which it is placed in contact.

Scen'o-graph. (*Drafting.*) The general view of a building, etc.

Ichnograph, the ground plan.

Orthograph, the front elevation.

Sciograph, a section, or a profile showing the interior.

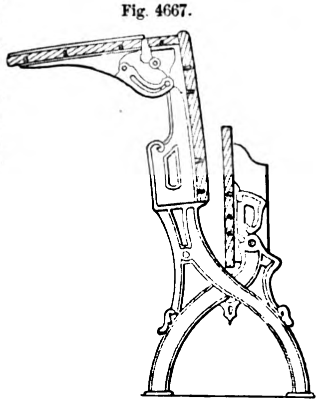
S-chis'el. A well-boring chisel whose cutting-face has a doubly curved form, like the letter "S."

Schmelze. (*Glass.*) A composition of silica, 500; minium, 800; niter, 100; potash, 100.

To 500 parts of which add: —

43 parts prismatic borax; 4 parts oxide tin; 4 parts oxide antimony; and a small portion of solution of gold in aqua regia. Heat for 12 hours in a crucible and anneal. The mixture is used for making a ruby glass for *flashing* colorless articles. See FLASHING.

Fig. 4667.



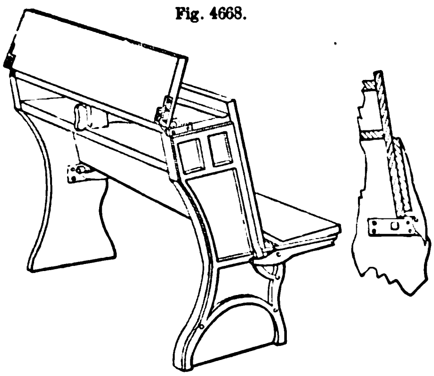
Folding School-Desk.

School-desk. One of compact form, usually having within itself a seat for one row of boys, backed by a desk for the next rear row; as in the illustrations.

In Fig. 4667, both seat and desk are folded, while the room is being swept; a convenient condition for stowage also during transportation.

Fig. 4668 is a form in which a flap of the desk only is folding, covering up the other half, which has

Fig. 4668.



School Desk and Seat.

recesses or drawers. See also DESK, Fig. 1618, page 689.

Schoon'er. (*Nautical.*) A two or three masted vessel whose sails are of the *fore-and-aft* class, *i. e.* extended on booms. The masts have but one splice, the topgallant, if any, forming part of the topmast stick.

When a schooner has none but fore-and-aft sails, she is termed a *fore-and-aft* schooner; if carrying a square foretopsail and fore-top-gallantsail, a *topsail* schooner. This latter rig, formerly common, has now become rare. Square-rigged vessels have also lower fore-and-aft sails, denominated spencers or trysails, but these are small and are brailed up to the gaff when furled, instead of being lowered like those of a schooner.

The first constructed was built by Captain Andrew Robinson in Gloucester, Mass., in 1713, and was so named from her *scooning* or sailing over the water as she was launched.

A Ballahore schooner has a foremast raking forward.

Schwan-pan. The Chinese abacus. It is very extensively employed by that people in their every-day business transactions, and enables computations to be made with great rapidity.

The method of the abacus gives an idea of position value in calculating, as in the Indian system, but was long unfruitful with the Greeks and Romans, because the idea of position was not carried into the recording of values. This first obtained general extension in the Middle Ages, especially after the zero sign had superseded the vacant space. See ABACUS.

The Indian numbers and the value from position must be more modern than the separation of the Indian and Zend, one or both, from the parent Aryan stock, for the Zend nation use the far less convenient Pehlevi numbers.

"The Arabs in Persia and on the Euphrates, as well as in Arabia, received in the ninth century the knowledge of the Indian numerical characters, through channels similar to those which had led to their acquaintance with the Indian algebra. Persians were employed at that period as revenue-collectors on the Indus; and the use of Indian numbers became general among the Arab revenue-officers, and extended to Northern Africa, opposite to the coast of Sicily."

Scim'i-ter. An Oriental form of saber. It is generally made much heavier toward the point than the saber of Western nations. *Cimeter.*

Sci'o-graph. (*Architecture.*) The profile or section of a building, to show the inside. See also SCENOGRAPH or list under 'GRAPH.

Sci-op'ti-con. A magic-lantern adapted for the exhibition of photographed objects. See MAGIC-LANTERN.

Scis'sel. (*Metal-working.*) *a.* Clippings of metallic plates.

b. Remainder of plates after planchets have been punched therefrom for coin.

Scis'sors. A cutting instrument consisting of two portions pivoted together and having blades which cut from opposite sides against an object placed between them. The *shears* is on a larger scale, but the action is similar.

The scissors of Atropos were made like sheep-shears, the bowspring at the junction of the bladed handles. Fosbroke says that "*forfices* were thus made," and were common among the Britons and Anglo-Saxons.

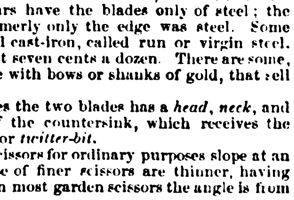
The blades with loops for the fingers and pivoted together by a rivet is of later date. Isidore, in the fifth century, refers to them as the tools of the barber and tailor.

A pair of bronze scissors, lying in a lady's work-basket, were found in an ancient tomb lately opened in Egypt. The handles were formed in the shape of a sphinx. The basket contained many articles of the toilet and work-basket, — needles, pins, combs, false hair, etc.

Scissors (*forfex*, *axicia*) and knives were used by the Roman cutlers.

In order to cut effectually, the blades, instead of being perfectly plain, as shown at *l*, and parallel to each other, are bowed and touch at two points, — the *cutting part*, which moves from hilt to point as the blades close, and the *riding part* *m*, a protuberance behind the screw-pin. The blades have a certain elasticity and touch at the shifting and constant parts as the rivet draws the two portions toward each other with a certain degree of strain.

Fig. 4669.



Scissors.

Wilkinson's patent (English) *n*, instead of a *riding part*, has a spring pin, which bears upon the shank of the blade, near the rivet, with sufficient power to force the edges into cutting contact.

Common scissors are made of shear-steel, with the blades hardened. Tailors' shears have the blades only of steel; the remainder is iron. Formerly only the edge was steel. Some scissors are made of good cast-iron, called run or virgin steel. Of these many are sold at seven cents a dozen. There are some, on the other hand, made with bows or shanks of gold, that sell for fifty dollars a pair.

The screw which unites the two blades has a *head*, *neck*, and *thread*. The bottom of the countersink, which receives the head, is called the shelf or *twitter-bit*.

The cutting-edges of scissors for ordinary purposes slope at an angle of about 40°; those of finer scissors are thinner, having an angle of about 30°; in most garden scissors the angle is from 40° to 50°.

Scissors are made from a bar of flat steel; the end for the bow is flattened, and punched with a small, round hole, which is gradually opened upon the *beak-iron* of the anvil. A shallow groove around the beak-iron serves to round the inside of the bows. The blade and joint of the scissors are made upon the flat of the anvil by means of the hammer, punch, and swages.

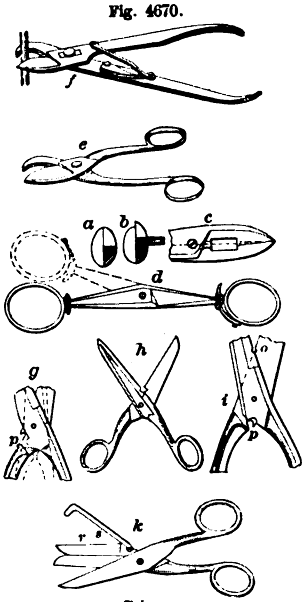
After softening, the shank and bow are improved by filing, the joint is squared, and the hole bored and fitted for the rivet. The blades are then ground, smooth-filed, burnished, matched in pairs, screwed together, and made to *walk* and *talk* well, as it is called. The blades are bound together with wire, the rivet is removed, and the blades are hardened and tempered. The wire is removed, and the blades are ground into shape and fitted together.

The bows and shanks are rubbed with fine emery and oil, the blades and shanks are fine ground, and the instrument is glazed

and polished. The blades are whetted, and certain parts are burnished.

Scissors embrace a number of varieties of construction, specially adapted for cutting fabrics, trimming plants, and for surgical and anatomical purposes.

Fig. 4670.



Scissors.

Flower and grape scissors have one of the blades made in two parts riveted together, so that after the stem is divided, it is held as in a pair of pliers. The edges are also rounded, to prevent injury to the plant. *a* shows a section of the scissors as closed, when not in use, and *b*, closed with the stem of a plant between the blades.

c. Button-hole shears are notched out near the joint-screw to enable the blades to cut at a little distance from the edge of the material.

Lamp-scissors have one blade very broad, and provided with a rim to prevent the snuff of the wick falling on the carpet.

Nail-scissors have short blades, and are made in pairs, one adapted for the left, and the other for the right hand.

d. Pocket-scissors have blades which may be locked by the point of one engaging a spring catch near the bow of the other; it is released by pressure with the nail, and turned into the position shown by the dotted lines for use.

e. The pruning scissors or shears have one broad hooked edge, which is often roughened, to prevent the twig from slipping; or they are made as at *f*, where the cutting-blade is slotted, so as to slide on the joint, moving forward as the blades are opened, and retracting so as to give a draw cut when they close. The handles, being unprovided with bows, are separated by a spring.

In *g h i* the blades have notches *v*, by which a wire or cord may be severed, and one or more (*p*) back of the joint for holding or pulling needles, wires, etc.

The scissors *k* have a knife *r* at the back of the blade, which is covered when not in use by a pivoted guard.

Surgical scissors are used in dividing soft parts which it is difficult to reach with a bistoury; also for renewing the edges of parts to be united by suture, removing excrescences, etc. They are made straight or curved, long or short, heavy or slender, to suit the form of the part to be used upon. They generally have long slender handles, and the blades are frequently curved or twisted.

g, Dr. Emmett's double-curved scissors for operations on vesico-vaginal fistula and cleft palate. See also STAPHYLLORAPHY.

h i are dissecting-scissors.

j, flower and fruit scissors.

k, roweling-scissors for veterinary uses.

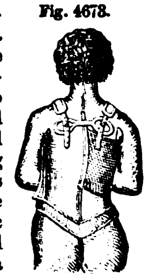
Scobs. Raspings.

Sco-li-o'sis Brace. (*Surgical.*) A brace for treating lateral curvature of the spine. Two elastic crutches are attached to the pelvic belt, and a strong upright bar relieves the spine of the weight of the trunk posteriorly. To the bar are connected two adjustable pads for the scapulæ, and just below these is a leathern band terminating in a number of strong elastic rubber webbings. This is passed around the protuberance obliquely and buckled to the pelvic belt in front, an inch or two beyond the linea alba, so as to exercise a gentle and continuous elastic pressure, at the same time rotating the ribs around their vertebral axes, to restore the spine to its normal position.

Fig. 4673.

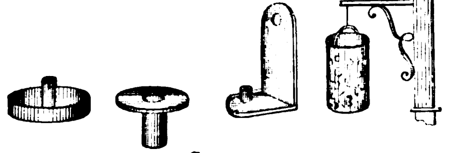


Scoliosis Brace.

Sconce. *a.* A candle-holder fixed to or projecting from a wall.

b. The tube in an ordinary candlestick in which the candle is inserted.

Fig. 4674.



Sconces.

Scoop. 1. *a.* A wooden shovel.

b. A thin metallic shovel with hollowing, capacious sides for handling grain. A grain-shovel.

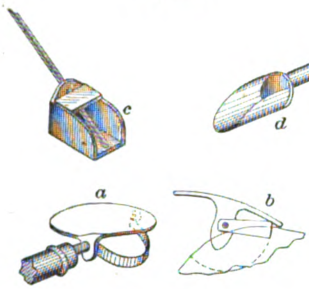
c. A familiar utensil (*d*, Fig. 4676), usually of tin-plate, for handling sugar, flour, etc.

2. A tool (*a b*) for scooping out potato-eyes from the tubers. The object is to save a part of the

Fig. 4675.

Potato-Scoop.

Fig. 4676.

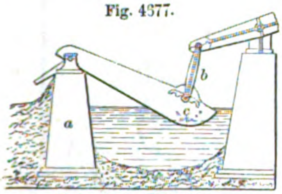


Scoops.

root for food. There are several varieties of it. A bent blade or a sharp-edged spoon will do for the work.

3. A bailing device used where the lift is moderate. Scoops are used for dipping liquors, for baling boats, for wetting sails in racing. *c* is a bailing scoop for use in ditching.

Fig. 4677.

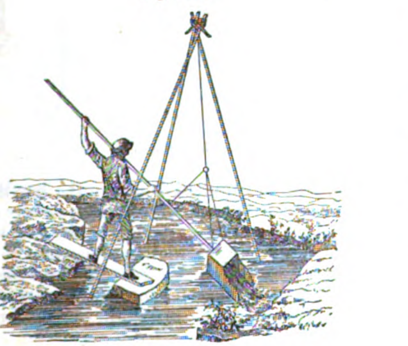


Fairbairn's Bail-Scoop.

Fairbairn's bail-scoop is worked by the single-acting Cornish engine. It is pivoted to a structure *a* on the bank, and adjustably connected by a rod *b* to the beam of the engine, so that the amount of its dip may be regulated. The other end of the engine working-beam is weighted to assist in raising the scoop when filled. Valves *c* in the bottom open when the scoop dips in the water and fall when it begins to rise. It is employed for raising water in draining, etc.

Fig. 4678 is a box shovel suspended from a tripod or pole, and used to dip water over a low bank. For-

Fig. 4678.

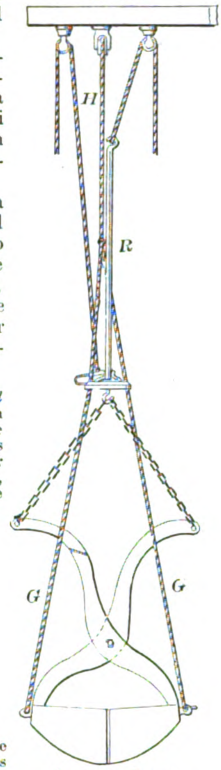


Dutch Scoop.

merly much used in Holland. Now sometimes used in bailing accumulated water from excavations for cellars.

4. (*Hydraulic Engineering.*) The bucket of a dredging-machine. That shown (Fig. 4679) is in two parts, firmly attached to their respective handles, which are pivoted. They are opened to enter the mud by hauling in the bifurcated rope *H G G*, and closed to retain and lift it by means of a rope attached to the rod *R*.

Fig. 4679.



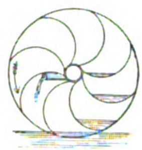
Dredging-Scoop.

5. (*Surgical.*) A spoon-shaped instrument for extracting foreign bodies, as a bullet from a wound, calculi from the bladder, objects from the meatus auditorius externus, nasal fossæ, etc.

Scoop-wheel. A form of the *tympanum* water-wheel in which the buckets are so curved as to scoop up the water into which they dip, raising a portion of the same and conducting it toward or into the axis, where it is discharged. See TYMPANUM.

Another form of the *scoop-wheel* is also adapted to raise water to an elevation equal to about half the diameter of the wheel, but delivers it at the periphery, instead of near the axis. Some of the *scoop-wheels*, used so extensively in draining the

Fig. 4680.



Scoop-Wheel.

fens of Lincolnshire, England, are made of cast-iron with wooden floats which form an angle of 45° with the horizon at the point where they deliver the water. The floats are otherwise like those of an undershot water-wheel, and move in a curved trough of masonry called the "*breasting*," into which they fit exactly, the lower end of the trough being in the drain, and the upper discharging into the chute, which carries off the water on a higher level. It is just the converse of the water-wheel, being *driven* by steam and *lifting* the water. The diameter of the wheel is so proportioned to the lift, that the surface of the water at the outfall is below its axis. The speed of the surface of the wheel is 6 feet per second; a wheel of 35 to 40 feet for a 15-feet lift.

One machine at Deeping Fen has a steam-engine of 80 horse-power, a water-wheel 28 feet in diameter, float-boards 5½ feet in depth, 5 feet wide, moving 6 feet per second, discharging 165 cubic feet of water per second. The float-boards dip 3 feet 4 inches; the average consumption of coal was 10¼ pounds per horse-power per hour. A better *duty* is now attained, probably. This engine of 80 horse-power and another of 60 take the place, but much exceed the former efficiency of 44 windmills.

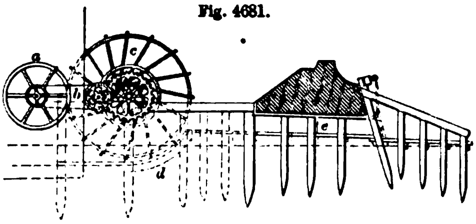
Littleport Fen has 2 steam-engines of 110 horse-power, to drain 28,000 acres; superseding 75 windmills. The *scoop-wheel* is 35 feet in diameter, and weighs 54 tons. The pinion is 4 feet in diameter, weighs 3,696 pounds, and makes 13 revolutions per minute. When the tide is high this pinion works into a cog-wheel 24 feet in diameter, having internal teeth; the float-boards on the *scoop-wheel* then move with a velocity of 212 feet per minute, and discharge in that time 3,519 cubic feet of water. When the tide is low, and so great an elevation of discharge is not required, the pinion is made to work in a cog-wheel 16 feet in diameter, and having external teeth; the float-boards then move at the rate of 318 feet per minute, and deliver 5,278 cubic feet in that time.

In that wet district it is estimated that 7,260,000 cubic feet of water are annually raised and carried off from every 1,000 acres. A 10-horse-power steam-engine can remove this in 232 hours. The rainfall is estimated at 3 inches per month, of which two thirds is to be lifted and removed artificially, which is 7,260 cubic feet to the acre. In the district referred to, this quantity was formerly increased by the natural drainings of 12,000 acres of highlands, amounting to 40,000 cubic feet per minute in a rainy season. By catch-water drains this is now intercepted and carried off by a special channel and outlet.

Glynn, C. E., England, makes the dip of his float-boards 5 feet, the axis 5 feet above the level of the outfall, the rate 6 feet per second at the circumference.

Fig. 4681 shows a *scoop-wheel* employed at Lough Foyle. The

Fig. 4681.



Scoop-Wheel at Lough Foyle (*Section of Wheel and Bank*).

engine fly-wheel *a* carries a pulley connected by a belt to the pulley *b*, whose shaft is provided with a pinion meshing with a spur-wheel on the shaft of the scoop-wheel *c*. *d* is the curved chase up which the water is driven into the chute *e*, passing through the embankment *f*, and conducted into the drain.

'Scope. A common termination for the names of instruments which make visual indications. See under the following heads: —

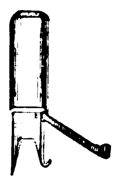
Scorch'ing. (*Metal-working.*) A *roughing out* of tools on the dry grindstone before they are hardened and tempered. So called from the great heat produced.

Score. (*Nautical.*) The groove around a block or a *dead-eye* for the strapping, *shroud*, or *backstay*. The holes in the block are for the *lanyard*.

A *heart* has one large hole with *scores* at the ends for the turns of the lanyard.

Scored Pul'ley. (*Machinery.*) A pulley grooved around its perimeter for a round band.

Fig. 4682.



1234567890

Scorer.

Scor'er. 1. A tool for marking timber. It has two scoop-shaped tools, one for straight lines, and the other adapted to revolve on a pivot for arcs or circles. Of these two forms, readable figures are made to number logs, scribe the gage-marks on barrels, etc.; as shown in the figure. A *race*-knife.

2. (*Joinery.*) An instrument employed to cut transversely the face of a board to enable it to be planed without slivering.

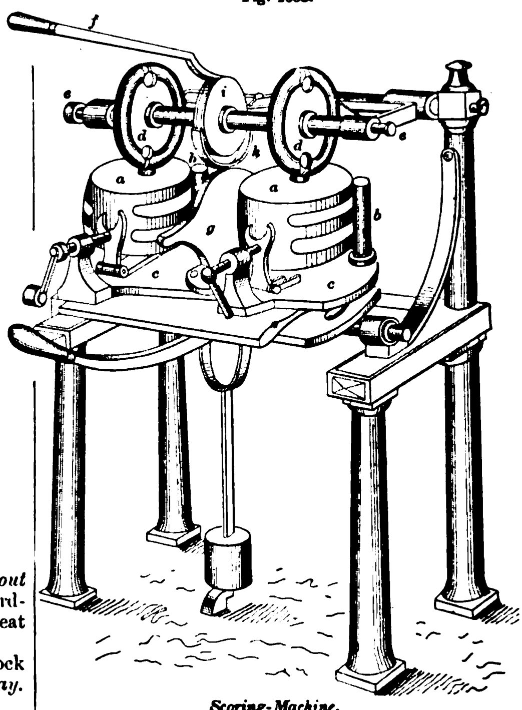
Sco'ri-a. Slaggy lava; dross thrown off from metals in fusion. See SLAG.

Sco'ri-fi'er. (*Assaying.*) A saucer of refractory clay for containing a charge of lead and the metal to be assayed. It is placed in the muffle of an assay-furnace. Also used in burning off inflammable matters from the sweepings of jeweler's shops, or to obtain the metallic portions from gold-lace, etc.

Scor'ing. (*Founding.*) The bursting or splitting of a casting, due to the strain caused by contraction. A term generally applied to cylinders and similar work, in which the core does not give way when the casting cools, and thereby causes its destruction.

Scor'ing-ma-chine'. (*Wood-working.*) A machine for cutting scores or grooves in blocks. It forms the groove around the longest diameters of the blocks for the reception of the ropes or straps by which the blocks are slung. The blocks *a* are clamped between pillars *b* on the table *c*, and exposed to the action of revolving cutters *d* above. These cutters rotate on a spindle pivoted in a swinging frame

Fig. 4683.

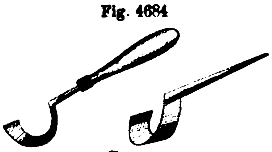


Scoring-Machine.

e, which is moved up and down by the handle *f*, being guided by a curved plate *g*, situate between the blocks. A curved plate attached to the frame *e* rests upon the guide *g*, and incloses but does not touch the pulley *i* by which the spindle is driven. The table itself is poised upon centers *k*, and is tilted up on either side so as to bring the blocks up to the cutters.

Scorp'er. A gouging-tool for working in a depression, as in hollowing bowls, butter-ladles, etc. Also used in removing wood or metal from depressed portions of carvings or chasings.

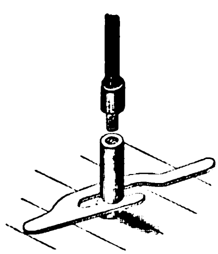
Fig. 4684



Scorper.

Scor'pi-on. A military engine for-

Fig. 4685.



Scotch.

merly used for throwing stones, etc.

Scotch. A prop, shoulder, strut, or support, as of a wheel, or of a log on inclined ground or on skids.

A slotted bar which slips upon a rod or pipe, and forms a bearing for a shoulder or collar thereon, so as to support it while a section above is being attached or detached. Used in boring and tubing wells.

Scotch Car'pet. An *ingrain*, *two* or *three ply* carpet, so named from the country where it is so extensively manufactured. Also called *Kidderminster*, from a town of that name, noted for its production. See TWO-PLY CARPET.

Scotch'man. (*Nautical.*) Stiff canvas wrapping or battening of wood around standing rigging to protect from chafing.

Sco'ti-a. (*Architecture.*) A hollow, curved molding. It occurs in the base of the Ionic column, and also in the projecting angle of the Doric corona.

Synonymous with *cavetto.*

Sco'to-graph. An instrument to assist in writing in the dark or without seeing.

Sco'to-scope. An optical instrument by which objects may be discerned in the dark.

"The scotoscope he [Mr. Reeve] gives me, and is of value; and a curious curiosity it is to discover objects in a dark room with." — PEPYS'S *Diary*, 1664.

Scots'man. (*Nautical.*) See SCOTCHMAN.

Scour'ing. 1. (*Woolen Manufacture.*) The pounding of woven woolen cloth by mallets in a trough provided with a detergent and water, in order to remove the oil and acquired dirt incident to its manufacture up to that point. As a process, scouring comes between *weaving* and *burling*. The process is sometimes termed *braying*, pounding being the action.

2. (*Metal.*) A process in the cleaning of iron-plate for tinning; or of metal in general for plating by electro-deposition or otherwise.

3. (*Hydraulics.*) The cleaning of a channel or sewer by a flush of water. See FLUSHING.

Scour'ing-ba'sin. (*Hydraulic Engineering.*) A reservoir in which tidal water is stored up to a certain level, and let out through sluices in a rapid stream for a few minutes, at low water, to scour a channel and its bar.

Scour'ing-ma-chine'. (*Woolen Manufacture.*) An apparatus consisting of two large rollers placed over a trough, through which cloth is passed after being woven, and is treated with stale urine and hog's dung.

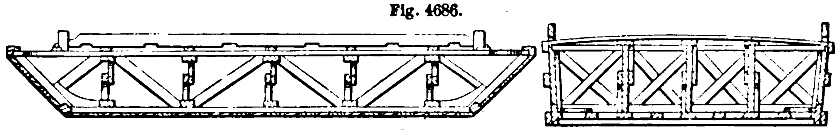
Scour'ing-stock. (*Woolen-manufacture.*) A machine like a fulling-mill, in which woven woolen cloths are pounded by heavy mallets in troughs provided with water and a detergent. The latter consists of urine, hog's dung, soda, or fuller's earth. The mallets are of oak, and oscillate on an axis, being raised by tappet-wheels acting upon their shanks. *Scouring* follows weaving, and is for the purpose of removing the oil added to the wool before *carding*, and also to rid the cloth of dirt or soil acquired in the course of manufacture. *Burling* and *fulling* succeed the scouring.

Sco'vel. (*Baking.*) A mop for cleansing ovens. A *malkin.*

Scow. (*Nautical.*) *a.* A flat-bottomed, square-ended boat, usually propelled by poles, or towed; being very cheaply and easily constructed, scows are employed in still waters for almost all purposes; they are made of all sizes, and often have decks.

b. A form of lighter or barge for carrying a heavy

Fig. 4686.



Scow.

deck-load. The example shows one strongly trussed, to prevent sagging or hogging.

Scrap. 1. The integuments that remain after the rendering of fat.

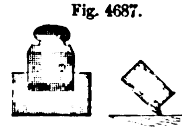
2. Broken iron, cast or wrought, for remelting or reworking.

Scrap-book. A blank-book into which cuttings from paper are pasted, or extracts written.

Scra'per. A tool or implement for removing material by a paring action. The term has many applications.

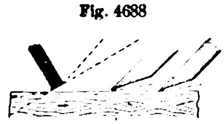
1. (*Wood-working.*) A steel plate, frequently made of a piece of saw-plate, with a square edge made sharp-angled, and burnished to raise a small

Fig. 4687.



Wood-Scrapers.

Fig. 4688

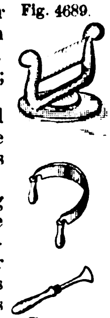


Cabinet-Maker's Scrapers.

bur or wire edge. The edge is used in giving a final dressing to wooden surfaces, veneers, etc. See Fig. 4687. It is held at an angle of 60°.

A piece of window-glass is frequently used where the wood is curly, knotty, or cross-grained, so as to plane with difficulty.

Fig. 4689.



Scrapers.

2. Allied to the former are a number of implements used in cleaning wooden surfaces of tar, paint, ink, and what not.

By the sailor, mast and deck scrapers; triangular tools on the ends of shanks.

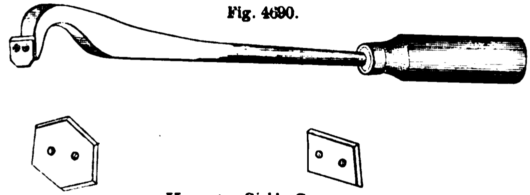
By the warehouseman or porter, bowed and with two handles, or else like the mast-scraper, to remove old directions from boxes and casks for reshipping.

3. A form of cutting-tool for taking shavings from the edge of a blade. The illustration (Fig. 4690) is one for sharpening the edges of sickle-sections for harvesters. The cutters have facets of different angles adapted to the faces of the objects from which shavings are to be cut.

4. (*Engraving.*) A three-sided cutting-tool (Fig. 4691) fluted, to make it more easy to sharpen. It is used in taking off the bur left by the etching-needle or dry-point, in obliterating lines, or working mezzotinto.

5. A large hoe for cleaning roads and streets.

Fig. 4690.



Harvester-Sickle Scraper.

6. An iron plate at a door to remove mud from the boots.

Fig. 4691.

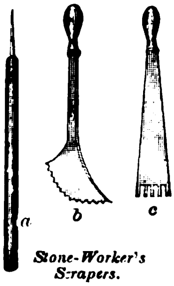
Engraver's Scraper.

7. (*Blasting.*) A spoon by which the detritus is removed from the hole made by the *jumper* or drill. See BLASTING-TOOLS.

8. A thin piece of wood shaped like a knife-blade and provided with a handle, used to scrape the sweat from horses.

9. (*Lithography.*) The board in a lithographic press whose edge is lowered on to the tympan-sheet, to bring the requisite pressure upon the paper, which lies upon the inked stone.

Fig. 4692.



Stone-Worker's Scrapers.

10. (*Stone.*) *a.* A toothed and steeled instrument for sinking flutings in marble, etc.

b. A tool used by stucco-workers.

11. A two-handled scoop (*a*, Fig. 4693), drawn by cattle or horses, and used in making and leveling roads, excavating ditches, canals, and cellars, and generally in raising and removing loosened soil or gravel to a short distance.

The usual mode of using it is to plow up the ground to be moved, and then to remove it by the scraper; if it be road-making, the soil at the sides is plowed, and then moved by the scraper to the middle of the road, where it is dumped by upsetting the scraper, to give the rounded shape to the road. It is leveled by a hoe, or by another scraper, to be described.

The Flemish use a similar implement.

Another form of scraper (*b*) is used in leveling heaps dumped from carts or the scrapers just described; it consists of an iron-shod board drawn with its edge along the ground and presented obliquely to the line of its draft, so as to give the soil a tendency to move toward the rear end. This scraper is drawn along on one side of the middle of the road and returns on the other, keeping the rear portion of the scraper toward the middle of the road, and tending to round it up so as to shed water.

A large machine, consisting of a frame supported near its midlength by an axle and a pair of wheels, and in front by a caster-wheel, was invented by Boase in England about 1830, and used in scraping mud from roads. It had a series of metallic plates, obliquely presented, and acting nearly independently, each being kept to its work by springs. It took a width of an ordinary carriage-track. (LOUDON, page 3749.)

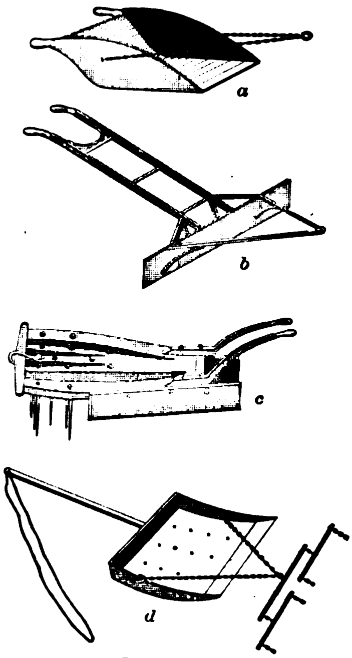
Harriott's road-scraper *c* (English) is designed to fill up the ruts of roads, and consists of a small harrow followed by a pair of converging scraper-boards. The teeth loosen the ridges of earth, gravel, or stones on the sides of the ruts, and the boards drag them into the ruts. It is managed by a man, and drawn by one or two horses.

The scraper is cited by Loudon (Ency. Agri., 1844) as an ingenious Dutch implement (*d*) for leveling soil and removing it short distances. The load, as with our own, is dumped by upsetting, but it has a long handle, recovered by a cord instead of by a pair of handles in continuation rearward of the side-boards.

The road-scraper (Fig. 4694) has an iron bottom fastened at the front, by chains *a*, to the transverse shaft *b*, and hung on a crank-shaft *c* behind.

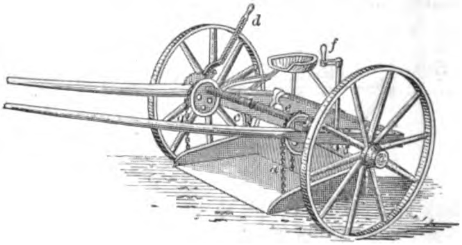
In driving along, the earth is thrown up naturally into the bottom of the scraper, and when full the whole can be raised clear of the surface and carried off to any desired point. The levers *d* and *e* enable the driver to elevate the scraper; the wheels in front, over which the chains pass, are eccentric, so that they lift like arms; and there is a ratchet-wheel and pawl at the end of the shaft the wheels are on, to hold the front edge of the scraper at any angle or desired hight. When the load is to be dumped, a vertical rod *f* is rotated, releasing the rear end of the scraper and allowing it to upset.

Fig. 4693.



Road-Scrapers.

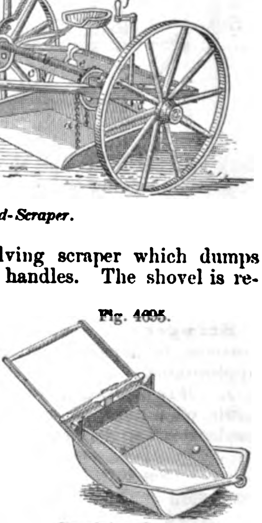
Fig. 4694.



Road-Scraper.

Fig. 4695 is a revolving scraper which dumps without throwing over handles. The shovel is released by a latch.

Fig. 4695.

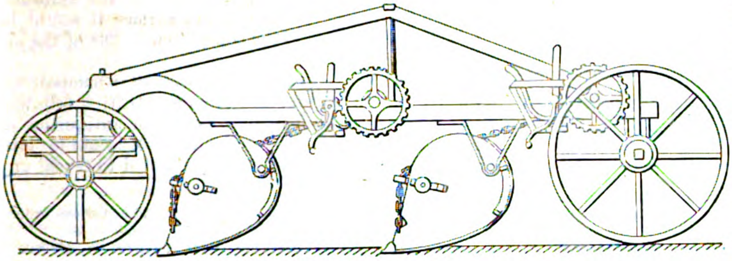


Revolving-Scraper.

In Fig. 4696, the scoops are pivoted by end gudgeons to pedestals beneath the wagon-frame, and are rotated and discharged by chains and winches operated as required by hand-cranks.

Fig. 4697 is an excavator for removing from the sides of railways earth that may have been washed down near or upon the track. The device is carried upon a car. The scoops project below it, and are operated by means of a windlass and lifting apparatus, so that the scoops can be raised and discharged when desired, the power of the locomotive operating them.

Fig. 4696.



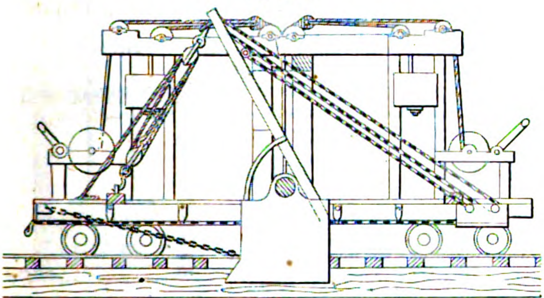
Excavator on Wagon-Frame.

Screed. (*Plastering.*) *a.* A strip of mortar 6 to 8 inches in width, and of the required thickness of the first coat, applied to the angles of a room or edge of a wall. They are laid on in parallel lines at intervals of 3 to 5 feet over the surface to be covered. When these have become sufficiently hard to withstand the pressure of a straight-edge, the interspaces between the screeds should be filled out flush with them, so as to produce a continuous and straight, even surface.

b. A wooden strip similarly placed.

Scra'per-press. (*Lithography.*) The old form of lithographic press, in which the stone and the paper for the impression, with a backing of parchment or paper, was run beneath a gate or straight-edge pressed violently upon the object passing beneath. It is now substituted by the roller-press.

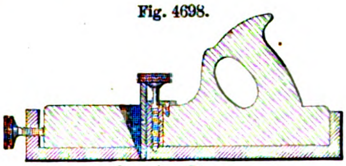
Fig. 4697.



Excavator on Railway-Car.

Scrap'ing-plane. A plane used by workers in iron, steel, brass, ivory, and hard woods. It has a vertical cutter or bit, with an edge ground at an angle of 70° or 80°, adjusted by a vertical screw, and held in place by an end screw and block.

Fig. 4698.



Scraping-Plane.

The scraping-plane for veneers, used in roughing the surface to be glued, has a notched bit, and is called a *toothing*-plane.

Scrap-ir'on. (*Founding.*) Irregular masses of iron spattered about or *run through* in pouring, are known as scraps, and all old metal which has at any time been cast, *wasters*, etc., accumulated for remelting, receives the general name of *scrap-iron*.

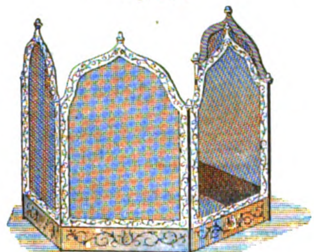
Scrap wrought-iron is piled, heated, and rerolled. It consists of cuttings, clippings, and worn-out small articles, such as horse-shoe nails, etc., which may be balled and worked over; when carefully selected and rewrought, the product possesses superior toughness and malleability.

Scratch-brush. A bundle of wires, whose protruding ends are used to clean files and for other purposes.

Scratch'er-up. A bookbinder's tool.

Screen. 1. A movable framework to keep off an excess of light or heat or cold; a separation; a partition. In ecclesiastical architecture, a screen denotes a partition of stone, wood, or metal.

Fig. 4699.



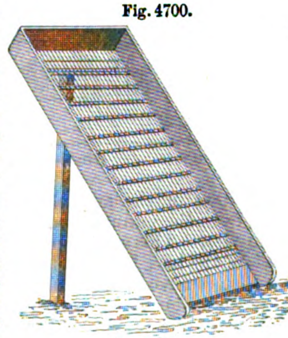
Fire-Screen.

The screen (Fig. 4699) is hinged so that it may be opened out more or less as required, or be folded up to occupy less space.

2. A sifter for coal, sand, grain, etc. The *screen*, *sifter*, *sieve*, *riddle*, vary in size, mode of application, and purpose.

a. Fig. 4700 shows the inclined screen, used in sifting sand and lime for mortar or plastering. The material is thrown a shovelful at a time on the upper part of the grating; the finer parts pass through the meshes, while those which are too large roll down the incline, the side of the screen being occasionally tapped to dislodge any which may stick.

Fig. 4700.

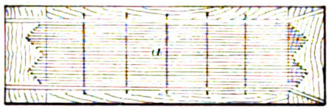


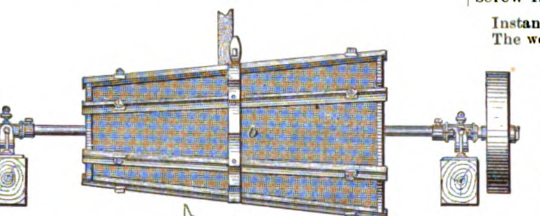
Sand-Screen.

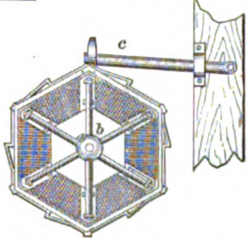
b. A wire-grated screen is employed for sorting crushed ores. In some cases it is made flat, and operated by a reciprocatory shaking movement, as in *a*, Fig. 4701; in others, the wire grating is stretched around the periphery of a drum *b*, which is caused to rotate, and is tapped by a knocker *c*, after the manner of a flour-bolter.

c. The grain is fed in at the higher end of the inclined cylinder *C* (Fig. 4702); the small grain and

Fig. 4701.







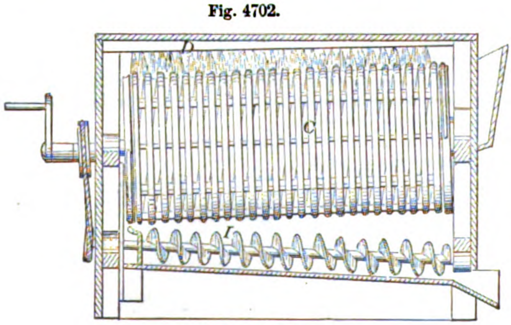
Screen for Comminuted Ores.

offal fall through and are removed by the conveyor *I* below, while the plump grain is discharged at the end into a separate spout.

Brushes *D* are employed to keep the interspaces clear.

3. (*Photography.*) That part of a camera-obscura upon which the visible image falls. It consists of a piece of plate-glass, one surface of which is finely ground, set in a wooden frame. The picture is rendered visible by

Fig. 4702.



Grain-Screen.

the reflection of the rays of light which form the picture, from the minute asperities upon the ground-glass surface. This screen, placed at right angles to the axis of the lens, is used while focusing the image, and is then removed to give place to the plate-holder.

4. (*Nautical.*) *a.* A partition made of canvas, used in place of a wooden bulkhead, where the latter would require to be frequently removed.

b. A kind of curtain, having an opening covered by a flap, placed in front of a magazine in time of action, or when the magazine is open. The cartridges in their passing-boxes are handed through the opening for distribution to the guns.

Screen Bulk'head. (*Shipwrighting.*) A bulkhead under the round-house.

Screen'ing-ma-chine'. (*Mining.*) An apparatus for sifting stamped ores, coals, etc.

Screw. 1. (*Machinery.*) A cylinder surrounded by a spiral ridge or groove, every part of which forms an equal angle with the axis of the cylinder, so that if developed on a plane surface it would be an inclined plane. It is considered as one of the six mechanical powers.

A careful examination in Lepsius, Champollion, Rosellini, Wilkinson, and other authorities, followed by a critical search among Egyptian antiquities in Dr. Abbott's and other collections (Museum of Historical Society, New York), has failed to reveal any screw in ancient Egypt.

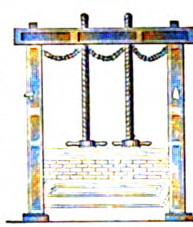
Instances of the screw in nature are found in various orders. The weapon of the *narwhal* is spiral, though it may not be immediately apparent what purpose is subserved thereby.

Some of the smaller animals are furnished with screws or gimlets, by which they penetrate the hardest woods, and even stone.

The vegetable world has its screw-like or spiral tendrils, which are mostly *right-handed*. The hop, however, is an exception, as it takes the *left-handed* whirl, *against the sun*, as it is called.

Screw-presses for clothes, wine, and oil were known to the Romans of the Empire.

Fig. 4703



Pompeian Clothes-Press.

A clothes-press, shown in the accompanying cut, was represented in a mural painting of the Chalcidium of Eumachia, at Pompeii. It has two upright screws with levers.

Vitruvius and Palladius mention the fruit-presses for wine and oil (*cochlea*).

The Archimedean water-elevator is mentioned by Diodorus Siculus, Strabo, and Vitruvius. See ARCHIMEDEAN SCREW.

The *helix* of the Greeks was a spiral for drawing ships on shore or launching them. Apparently a screw, and ascribed to Archimedes.

"And when there was great enquiry as to the best method of launching the great ship of Hiero of Syracuse into the sea, Archimedes the mechanician launched it by himself with the aid of a few persons. For having prepared a *helix* [screw], he drew this vessel, enormous as it was, down into the sea. And Archimedes was the first person who ever invented the helix — MOSCHION, *quoted in the* "*Deipnosophists*" *by* ATHENÆUS, A. D. 220.

The *differential screw* was invented by John Hunter, the celebrated surgeon. It is a combination of screws, so arranged that the motion of the object to which the device is applied is equal to the difference between the pitches of the screws. See DIFFERENTIAL SCREW.

The *endless* or *perpetual screw* is a screw without longitudinal motion, acting upon the cogs of a wheel. See WORM-WHEEL; PERPETUAL SCREW.

The parts of a screw are the *head*, *barrel*, or *stem*, *thread*, and *point*. The head has a *slit*, *nick*, or *square*.

The threads are *convex* or *external*, *concave* or *internal*.

In number they vary, as *single*, *double*, *triple*; the numbers representing the individual threads, and those above single being known as *multiplex-threaded*.

In pitch; as *coarse*, *fine*.

In shape; as *square*, *angular*, *round*.

In material; as *wooden*, *iron*, *brass*, etc.

In direction; as *left hand*, *right hand*.

In purpose; as *binding*, *set*, *wood*, *adjusting*, *attachment*, *regulating*, *feed*, *micrometer*, *propeller*, *water* (Archimedean), *endless*, *differential*.

Known by attachments; as *winged* or *thumb* screw.

Screws are *cast*, *turned*, *chased*, *swaged*, *spun*, as may suit the purpose or material.

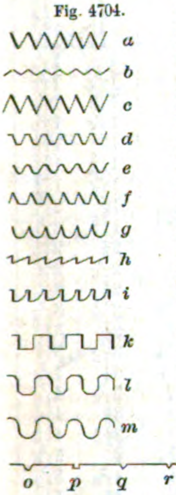
The word also gives names to devices or machines; as *screw-bolt*, *screw-jack*, *screw-plug*, *screw-press*, *screw-propeller*, *screw-tap*, etc. See *infra*.

Pappus Alexandrinus, a Greek mathematician of the fourth century, describes a method of forming screws by means of a templet of thin brass in the shape of a right-angled triangle, to be wound around the cylinder which was to be cut, tracing the spiral line of thread along the edge of this templet, and subsequently removing the metal between the threads. Directions are also given for setting off and forming the teeth of the corresponding worm-wheel.

One of the earliest attempts to obtain extreme accuracy in originating screw-threads was by Ramsden, in his dividing-engine, 1766. See DIVIDING-ENGINE.

Great attention was subsequently devoted to the subject by Maudslay, who, on entering upon his distinguished career as a mechanician, found the screws, which perform so many important functions in mill and machine work, in a very imperfect state. In his efforts to produce screws with perfectly uniform threads, he employed various modifications of the chain or band of steel; the inclined knife, the inclined plane, and all other known methods. He gave the preference to the inclined knife, applied against a cylinder revolving in the lathe, by means of a slide running upon the bar of the lathe, — a process which, besides being very rapid, reduced the mechanism to its utmost simplicity. The knife was adjusted by set-screws, and the correctness of the thread cut by it was tested first upon rods of wood, and afterward upon cylinders of the softer metals, until a screw was produced which was considered sufficiently accurate to serve as a guide-screw, in an apparatus similar in principle to the more modern screw-cutting lathe.

Fig. 4704.



Screw-Threads.

During the course of Maudslay's experiments, his friend, Mr., afterward Sir J. Barton, succeeded in originating screws of equal correctness, by employing a chain or flexible band for traversing the tool. Maudslay made many improvements in the system of taps and dies, and, in the opinion of Holtzapffel, between the years 1800 - 1810, effected nearly the whole change from the old and imperfect method to the modern, systematic, and exact method now generally practiced. He pursued the subject with more or less ardor and at great expense until his death, in 1835.

Fig. 4704 represents sections of various screw-threads. *a* has angles of about 60°, and is used for most screws made of wood, and in many made of metal and employed for uniting metals.

b, a shallow-threaded screw, having angles of nearly 90°, used for the thin tubes of telescopes.

c, a deep-threaded screw, having angles of 45°, used in mathematical and some other instruments.

d, the threads are truncated, the better to enable the bolt to resist withdrawal.

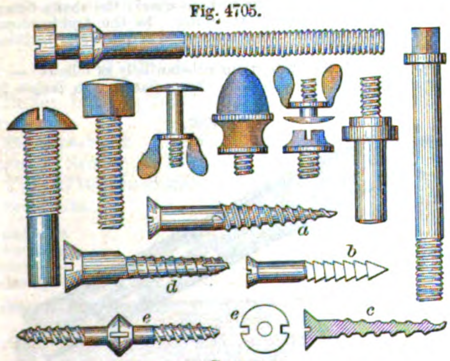
e, angular thread with rounded top and bottom, sometimes called round thread; much used in engineering.

f, angular thread, truncated at the bottom; used for joinery work.

g, rounded thread; used for the same purposes.

h, the lower sides of the threads are beveled at a comparatively small angle to the axis; the upper side is perpendicular thereto, giving a firmer hold: this is used in joinery work.

Fig. 4705.



Screws.

i, German screw, for wood; the lower side of the thread is hollowed out, leaving more of the wood to support the screw.

k, square-threaded screw; the space and thread are usually of equal width, and the depth is either equal to the width or a trifle more.

l is derived from the preceding by the truncation of its angles.

m, the angles of the former are entirely obliterated, forming a rounded thread.

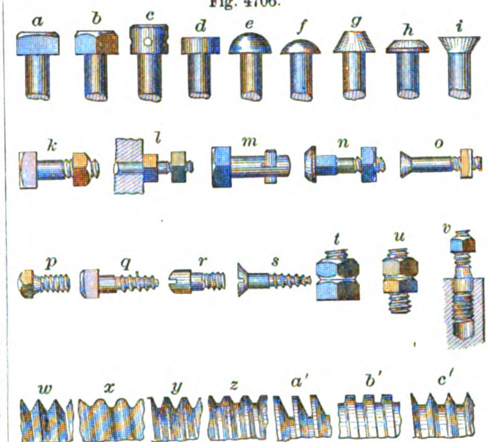
A steep-threaded screw is used for rapid turning; it has a single shallow groove, which may be of angular, square, or circular section, leaving much of the original cylinder remaining.

o to *r* are screws specially adapted to various specific purposes.

Fig. 4705 shows a cluster of screws of various forms and sizes for carriage-makers and carpenters. Of the screws at the lower part of the cut, *a b c d* have peculiar threads to lead in readily or oppose endways retraction. *e* is a dowel-screw, having a head at midlength, and right and left screws which draw two pieces together.

Fig. 4706 illustrates various forms of screw bolt-heads, technically known as, —

Fig. 4706.



Screws and Screw-Bolts.

a, square.	*f*, oval.
b, hexagon.	*g*, conical.
c, capstan.	*h*, pan.
d, cheese.	*i*, countersunk.
e, snap.	

Screw-bolts are designated as, —

k, machine.	*q*, coach-screw.
l, collar.	*r*, machine-screw.
m, cotter-bolt.	*s*, wood-screw.
n, carriage.	*t*, double-nut.
o, tire.	*u*, check-nut.
p, set-screw.	*v*, stud.

The more usual forms of screw-thread are known as, —

w, V-thread.	*a′*, ratchet.
x, English standard.	*b′*, square.
y, United States standard.	*c′*, wood-screw thread.
z, bastard.	

A watch contains forty-four screws. Little automatic machines convert steel wire into minute screws, pare down and nick their heads. They are polished, and then brought to "spring temper" by heating, which leaves them of a blue color.

Machines in a watch-factory will cut screws with 500 threads to the inch; the finest used in the watch have 250. These threads are invisible to the naked eye, and it takes 144,000 of the screws to weigh a pound. A pound of them is worth six pounds of pure gold. Lay one upon a piece of white paper, and it looks like a tiny steel filing.

Screws for the best compensation-balances are of gold. A ten-dollar piece will furnish material for 650 of them. The compensation-balance comes from the punching-room a solid piece of steel as large and heavy as a new penny, and inclosed in a rim of brass.

It is ground down, crossed out, and polished till it becomes a slender wheel, — the outer rim brass, the inner wheel and cross-bar steel. Through the double rim twenty-two holes are drilled for the screws. A chuck whirls the wheel around 4,800 times a minute, while a lad makes each hole by applying three tiny drills, one after the other. Screws of gold or brass are then put in, and the balance is completed.

In France, as long ago as 1844, soles were secured to shoes by screws.

Rough nut = one and one-half diameter of bolt + 1/8.
Finished nut = one and one-half diameter of bolt + 1/16.
Rough nut = diameter of bolt.
Finished nut = diameter of bolt — 1/16.

Rough head = one and one-half diameter of bolt + 1/8.
Finished head = one and one-half diameter of bolt + 1/16.
Rough head = one-half distance between parallel sides of head.
Finished head = diameter of bolt — 1/16.

2. (*Hydraulics.*) The first screw may have been the water-screw of Archimedes, about 236 B. C.

"The Egyptians have an easy way to water the land by means of a certain engine invented by Archimedes, the Syracusan, which, from its form, is called *cochlea*." — DIODORUS SICULUS (60 B. C.).

It is believed that Archimedes designed the wheel to be moved by the current of the Nile, and it is certainly capable of being moved by a current of sufficient speed, or one deflected by wing dams to act upon the floats of the wheel.

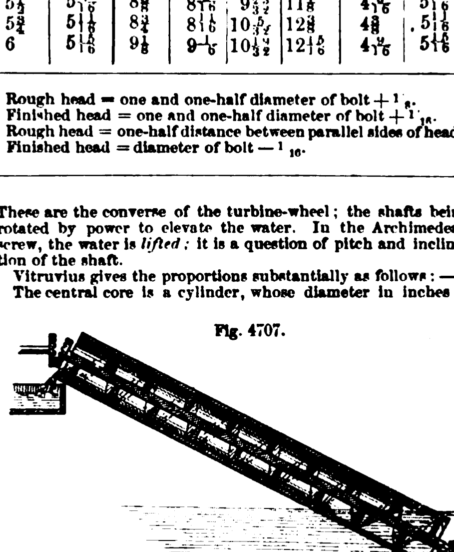
Extending through the inclined shaft is a spiral passage, which may be compared to a large tube wound around an axis. The lower end of the shaft is submerged, and the end of the spiral tube thus dips up the water as the shaft is revolved by the wheel.

If the spirally flanged shaft be revolved with sufficient speed, the pitch may be very steep, and yet raise the water, as shown under the head PUMPS, CENTRIFUGAL; but this is not the primary idea of the Archimedean water-screw, the pitch of which is slight, and the water flows naturally along the spiral canal as the shaft revolves, flowing with a rapidity proportionate to the speed, pitch, and capacity, or sectional area. It is not *forced*, as in the centrifugal pumps of Gynne, Guerick, and others. These are the converse of the turbine-wheel; the shafts being rotated by power to elevate the water. In the Archimedean screw, the water is *lifted*; it is a question of pitch and inclination of the shaft.

Vitruvius gives the proportions substantially as follows: —

The central core is a cylinder, whose diameter in inches is

Fig. 4707.



Archimedean Screw.

equal to its length in feet. Eight spiral flanges are carried around this core of such a width that the diameter of the screw is equal to $\frac{1}{4}$ of the length. The pitch is equal to the diameter. The barrel is inclined, and has pivots at the ends, which turn in gudgeons.

These proportions and forms have been variously modified. For instance, —

1 A pipe has been twisted around an axle and suitably supported in bearings, at a proper inclination.

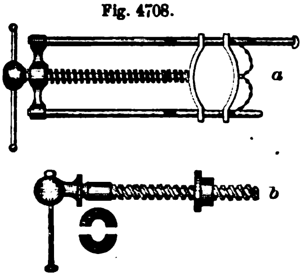
2. The number of channels has been multiplied, several distinct parallel passages winding around the central core.

3. Instead of building passages between the newel and the cylinder, a screw with one or more threads has been made to revolve in a semi-cylindrical, inclined trough

The steeper the pitch of the screw, the greater must be the inclination, as the channels must decline from the plane of the horizon, that the water may, as the screw turns, continually descend in its course.

3. (*Steam Navigation.*) A propeller with spiral wings, and having an axis parallel with the *level line* of the vessel. See SCREW-PROPELLER.

Fig. 4708.



a. Rigging-Screw; b. Bench-Screw.

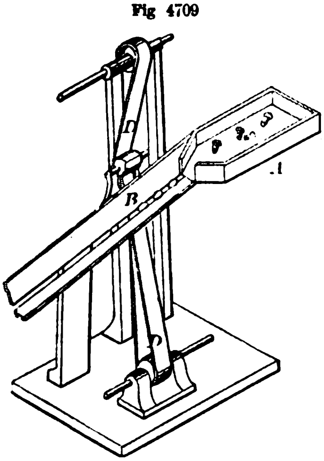
Transverse screws have been suggested or used for maneuvering.

4. A tool working by means of a screw. See SCREW-CLAMP, etc.

Screw-alley. (*Shipwrighting.*) A passage-way along the shaft of a screw-propeller, allowing access for the men who examine and attend to the bearings.

Screw-blank Feed'er. In the screw-blank feeding-apparatus (Fig. 4709), the blanks are placed in the hopper *A*. By means of an angular roller rotated by the belt *D D*, a shaking motion is imparted to the hopper and trough *B*, down which the blanks pass one by one on their way to the thread-cutting dies.

Fig 4709



Screw-Blank Feeder.

Screw-blast Ma-chine'. (*Blower.*) A form of blowing-engine, in which the blast is driven through the cylinder by a spiral vane rotating rapidly on its axis.

Screw-bolt. One having a screw-thread on its shank. See BOLT, Fig. 768.

Fig. 4710 illustrates various carriage screw-bolts.

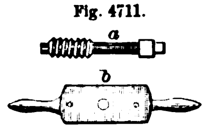
Screw-box. (*Wood-Working.*) A device for cutting the threads on wooden screws. It is similar in construction and operation to the screw-plate used for metallic screws, as is also the tap for cutting interior screw-threads in wood. *a* is the tap, *b* the *box*.

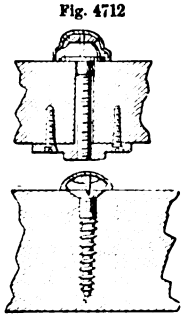
Screw-cap. 1. A cover to protect or conceal the head of a screw.

Fig. 4711.



Screw-Box.

Fig. 4712



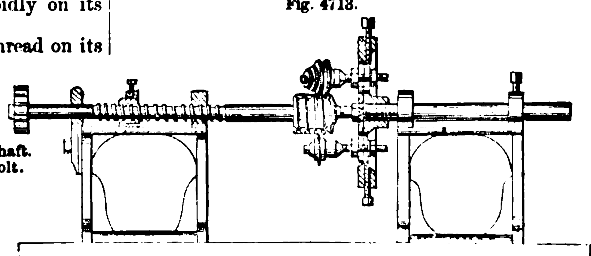
Screw-Cap.

In Fig. 4712, the cap has a small screw-stem in its center, which is screwed into the head of the main screw after the latter has been driven into the wood.

2. A cover for a fruit-jar. See FRUIT-JAR, Fig. 2131, page 920.

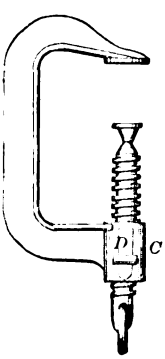
Fig. 4713 is a machine for threading screw-caps of sheet-metal. The sheet-metal cap is placed upon a threaded head upon the screw-threaded mandrel. Rotary and advancing motion being communicated to the mandrel, the cap is brought under

Fig. 4713.



Machine for Threading Screw-Caps.

Fig 4714.



Screw-Clamp.

the action of the screw-threaded roll-dies surrounding it and a thread formed thereon.

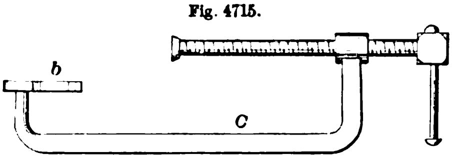
Screw-clamp. A clamp which acts by means of a screw. Different varieties are used by shipwrights for holding planking to the knees while driving the treenails, by house-carpenters, harness-makers, and other artisans.. That shown (Fig. 4714) has an expanding nut *C* having pivoted levers *D* by which it is opened out to allow the screw to be placed nearly to its position before commencing to turn it.

In Fig. 4715, the arm *C* has a serrated foot *b*, which holds firmly against the knee while the plank is pressed home by the screw.

In Fig. 4716, the fulcral screw has a free nut and the clamping screw a jam nut.

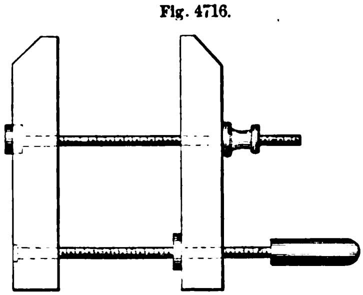
Screw-col'lar. (*Optics.*) The means of adjustment for relative distance between the front and the posterior pairs of an achromatic objective, designed to secure perfect definition with differing thickness of covering glass.

Fig. 4715.



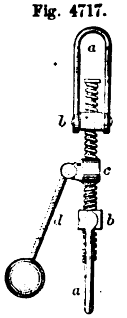
Planking-Screw.

Fig. 4716.



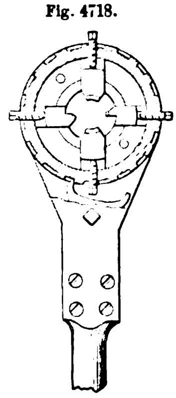
Hand-Screw Clamp.

Fig. 4717.



Screw-Coupling.

Fig. 4718.



Screw-Cutter.

Screw-coup'ling. *a.* A device for joining the ends of two vertical rods or chains and giving them any desired degree of tension. The ends are secured to the loops *a a* swiveled to the nuts *b b*. The cylindrical coupling-nut *c* has a pivoted, weighted arm *d*, which insures its verticality and serves as a spanner.

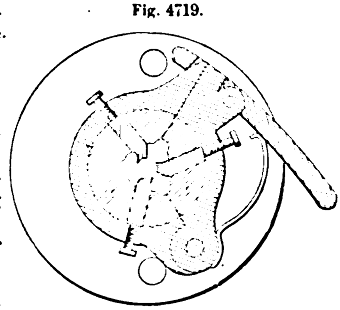
b. A screw-socket for uniting pipes or rods.

Screw-cut'ter. An implement for cutting screws. As a hand-tool it is known as a die, and the complete device as *stock and die*.

In Fig. 4718, the revolvable head has radial bearing-blocks or cutters, which are adjustable from the outside. See also SCREW-PLATE. Machines for the purpose are known as *screw-cutting lathes, screw-cutting machines, turret-lathes*, etc.

Screw-cut'ting Chuck. A lathe-chuck adapted to cut threads on rods or screw-blanks. In the example, the chuck is made in two parts, one hinged to the other. They are held together by a handle and a spring pawl.

Fig. 4719.



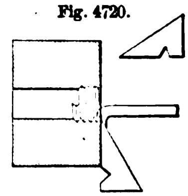
Screw-Cutting Chuck.

Screw-cut'ting Die. The cutting device in a SCREW-PLATE, SCREW-STOCK, or SCREW-CUTTING MACHINE (which see).

Screw-cut'ting En'gine. See SCREW-CUTTING MACHINE.

Screw-cut'ting Gage. A device having angles by which is determined the inclination of the point of the cutting-tool, and also the inclination of the tool when arranged in the post for cutting the thread.

Fig. 4720.



Screw-Cutting Gage.

Screw-cut'ting Lathe. A machine of this kind was invented by Besson in France as early as 1569. It embraced a guide-screw, which was caused to advance the cutting-tool at the same time that the work was rotated by means of a series of cords, pulleys, and weights. Screws of any pitch might be cut by using pulleys of different diameters, and right or left hand threads by crossing or uncrossing the belts.

It was farther improved by Hindley, a watchmaker of York, England, about 1741. It was a watchmaker's and bench instrument for many years before it had any place in the machine-shop.

Fig. 4721 illustrates Varley's screw-cutting apparatus, applicable to the hand-lathe. The mandrel *a* is surrounded by a tube on which four threads of different pitch are cut. The bar *b* carries at one end a piece *c* filed to correspond with the thread to be used as a guide, and has at the other a socket, in which is inserted a screw tool *e* corresponding to the thread to be cut. The bar *b* is held to the mandrel and the work by hand, the piece *c* being supported on the horizontal plate *d* parallel with the mandrel, and the tool *e* upon the lathe-rest *f*.

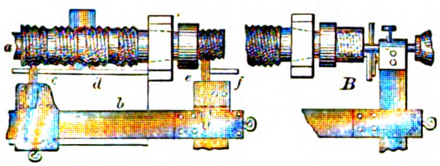
The guide *c* and screw-tool are traversed simultaneously to the left by the screw-guide, and when the tool meets the shoulder of the work, the bar is withdrawn and shifted to the right for a repetition of the cut, and so on until the screw is complete.

Beneath the tool is a screw which rubs against the lathe-rest and acts as a stop, serving to make the screw either cylindrical or conical, as the rest is placed parallel or obliquely.

For the internal screw the tool is placed parallel with the bar, as at *B*, and the cheek-screw is applied on the side toward the center, against a short bar parallel with the axis of the lathe.

Devices of this kind are not adapted for cutting accurate

Fig. 4721.

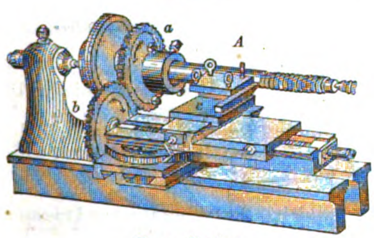


Screw-Cutting.

screws of considerable length or great diameter. For these a lathe is employed, in which the traverse of the tool is effected by a long guide-screw connected with the mandrel, which carries the work by a system of change-wheels

The most simple application of these is shown at *A*, Fig. 4722. The work is attached to the lathe-mandrel by a chuck, to which is secured a wheel *a* gearing with a wheel on the guide-screw, which moves the slide-rest *c* that carries the screw-cutting tool. The wheels *a b*, being equal, will rotate with equal velocity in opposite directions, so that the screw-thread cut will be precisely similar to that of the guide-screw, but reversed; consequently, to produce a right-handed screw, a left-handed guide-screw must be employed. To enable the screw which moves the slide-rest to produce either right or left hand screws, and to cut

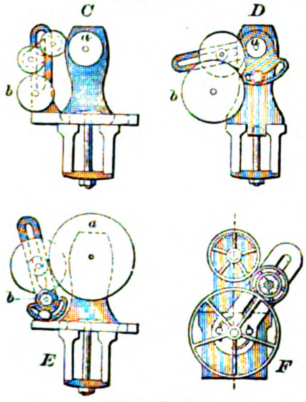
Fig. 4722.



Screw-Cutting.

threads of varying pitch, intermediate wheels, called *change-wheels*, are introduced between *a* and *b*. Thus one intermediate wheel between the two causes them to move in the same direction, cutting a thread corresponding in direction to that of the guide-screw, while the introduction of a second, causing them to move in opposite directions, makes the tool cut a reverse thread. The diameter and number of teeth in the intermediate wheels also being varied, causes a difference of velocity in the rotation of the guide-screw and mandrel, so that they do not advance with equal rapidity, and the thread cut may have a pitch of any determinate proportion, either greater or less than that of the guide-screw. For this purpose, with the better class of lathes, a large variety of change-wheels is employed, enabling threads of any size usually occurring in practice to be cut. The depth and form of the teeth are, of course, regulated by the shape of the cutting-tool

Fig. 4723.



Screw-Cutting

In order to support the axes on which the change-wheels revolve, a pedestal, supported by the bearers or a bracket at the lathe-head, is employed; these are susceptible of many modifications, three of which are illustrated at *C D E*, Fig 4723.

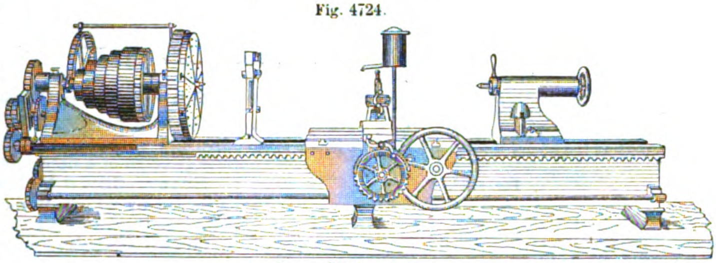
a a a represent the wheels upon the mandrel, and *b b b* those upon the slide-rest.

The rectangular bracket at *C* has two straight mortises, by one of which it is bolted to the bearers of the lathe, and in the other it carries a pair of wheels pivoted in a short piece, which may be fixed at any angle or hight in the mortise, so that either or both may be employed.

In *D* the intermediate wheel or wheels are carried by a radial arm, which has partial rotation around the mándrel, and is fixed to the lathe-head by a bolt passed through the curved mortise.

In *E* a similar radial arm is adjustable around the axis of the slide-rest screw in the fixed bracket Sometimes the wheel *b* is carried by the pedestal or arm fixed to the bed or headstock of the lathe, in order that a shaft or spindle may proceed from

Fig. 4724.



Screw-Cutting Lathe.

this wheel, and be coupled to the slide-rest screw by a socket, enabling the rest to be placed at any point of the bearer for cutting a screw on the end of a long rod, or for cutting a screw which exceeds in length the traverse of the rest, which may then be performed at two operations.

In the larger and more improved class of lathes, specially designed for cutting screws, nearly the entire length of the bed is used as a slide-rest, the tool-carriage traversing directly upon the bed. A change-wheel arrangement, similar to *F*, Fig 4723, is frequently adopted. The guide-screw extends through the middle of the bed, projecting at one end. The slide-rest is attached to the screw by a clasp nut, so as to be detached therefrom and moved independently when required. The train of wheels is placed at the left extremity of the lathe, and the intermediate wheels are journaled upon a radial arm which has one or two straight mortises which receive their journals, and two circularly curved arms which permit its partial rotation around the screw, and enable it to be fixed at any required angle by means of set-screws.

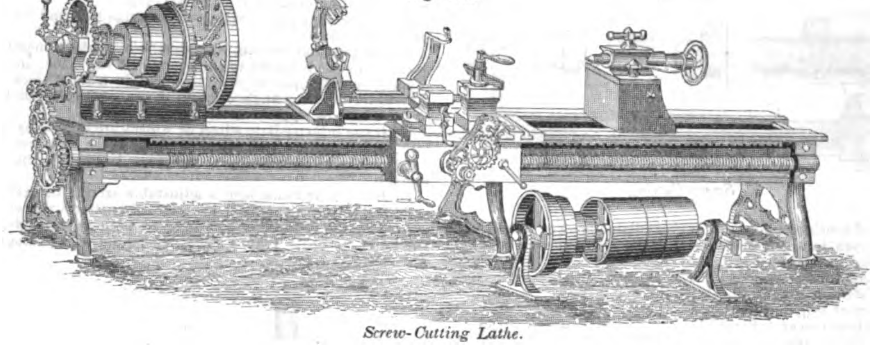
The lathe (Fig. 4724) has screw-cutting and turning feeds, so arranged that one may be instantly exchanged for the other, when both are in gear with the spindle. The turning feed is adjustable to any speed between the fastest and slowest. The slide-rest is compound; the puppet-head has an improved hold-down, insuring its center being in line with the axis of the live spindle, and is provided with a concentric hold-fast.

The lathe (Fig 4725) is adapted for cutting screws, and also for boring cylinders, turning and cutting shafting, and for miscellaneous work. The system of change-wheels is more complicated than those described, admitting a great variety of relative graduations of speed between the guide-screw and the mandrel. Such lathes are made of lengths up to 22 feet, or 18 feet between centers, enabling threads of nearly that length to be cut.

Screw-cut'ting Ma-chine'. A machine on the principle of the lathe, the rod to be threaded being suspended between the head and tail centers, and being dogged to a face-plate on the mandrel of the former.

The motion is derived from a bevel-pinion which engages one or the other of the bevel-wheels to rotate the feed-screws in one or the other direction; for feeding or returning the slide-rest to the commencing point; for for cutting right or left handed screws The feed-screws are shown a little within the ways of the machine, and are turned by pinions into which meshes the spur-wheel on the mandrel of the lathe-head. By the intervention of suitable gearing, such a proportion is established between the rotation of the rod on which the screw is to be cut, and the feed-screws themselves, as to obtain any required pitch of thread on the rod The rate of rotation of the rod being assumed as permanent, an equal rate of the feed-screws will cut a thread of a pitch equal to that of the feed-screws. If the latter are rotated at a slower rate, the pitch of the screw will be less; if the feed-screws are rotated faster than the rod under treatment, the pitch of the screw on the lathe will be proportionately increased. See Bolt-cutter; Bolt-threading Machine; Turret-lathe; Screw-cutting Lathe.

Fig 4725.

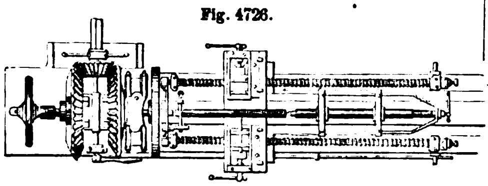


Screw-Cutting Lathe.

General Sir Samuel Bentham made machines for cutting wood-screws by means of rotary cutters.

In Royon's machine (Fig. 4727), the die-chuck *E* is hollow, and is turned by the hollow shaft *B*, rotated by a pinion mesh-

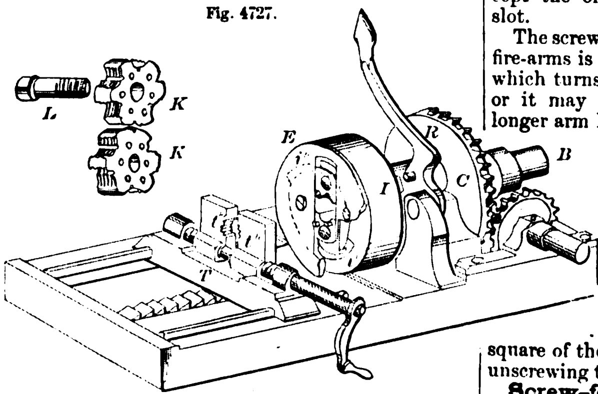
Fig. 4726.



Screw-Cutting Machine.

ing with the bevel-wheel *C*. The dies *K K* are rotatable, have several sets of threads adapted to screws of different sizes and pitch, are secured within the chuck by screws *L*, are caused to approach or recede from each other by moving in the eccentric slots *i′ i″* upon turning the ring *I*, and are fixed at the proper distance apart by a movement of the lever *R*. *T* is the carriage on which the screws or bolts are held between the jaws *t″ t‴*, approached by a right and left hand screw. In tapping nuts, the nuts are held by a hollow-ended mandrel inserted through

Fig. 4727.



Screw-Cutting Machine.

an opening in the chuck *E*, into the hollow shaft, while the tap is grasped by the jaws *t″ t‴* of the carriage.

Screw-dock. (*Hydraulic Engineering.*) A contrivance for lifting a vessel out of the water, in order that the bottom may be examined and cleaned.

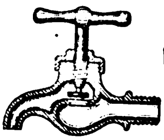
The vessel to be raised by this apparatus is floated over a platform of wood, sunk to the depth of about 10 feet below the surface of the water, and suspended from a strongly built wooden framework by iron screws from 4½ to 5 inches in diameter. This platform has several *shores* on its surface, which are brought to bear equally on the vessel's bottom, to prevent her from heeling over on being raised out of the water. The platform is gradually raised to the surface of the water, carrying the vessel high and dry, suspended between the wooden frames.

Screw-down Cock. A cock provided with a valve which is screwed down to its seat to prevent the flow of liquid, and raised more or less to permit the passage of a determinate quantity.

Screw-down Valve. A valve whose stem has a thread by which it may be screwed down to its seat.

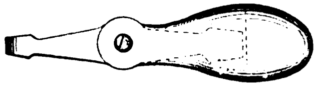
Screw-driv′er. A tool for turning screws in or out of their places. It has an end like a blunt chisel, which enters the *nick* in the screw-head.

Fig. 4728.



Screw-Down Cock.

Fig 4729.

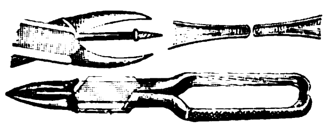


Screw-Driver.

In that shown (Fig. 4729), the handle is slotted to receive pivoted blades of different sizes, which, except the one in use, are turned back within the slot.

The screw-driver for taking apart and re-assembling fire-arms is composed of two blades of steel, one of which turns on a pivot, passing through the other, or it may have an additional pivoted arm. The longer arm has a perforation at one end fitting the square of the "cone" or nipple, for the purpose of unscrewing the nipple from its seat.

Fig. 4730.



Hulliken's Screw-Forceps.

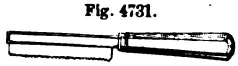
Screw-for′ceps. (*Surgical.*) A dentist's instrument. Between the jaws is a screw which is protruded into the nerve-canal, so as to fill it and prevent the crushing of the tooth when the pressure of the jaws comes upon it.

Screw-gear. (*Machinery.*) The *worm* and *worm-wheel*, or endless screw and pinion.

Screw-head File. A feather-edged file for nicking screw-heads.

Screw-head Saw. The saw for cutting nicks in screw-heads is strengthened by a back-plate like a tenon-saw.

Fig. 4731.



Screw-Head Saw.

In machine-made screws for carpenter's use,

and known as *wood-screws*, the nick is made by a circular saw of small diameter.

Screw-hook. (*Surgical.*) An instrument for withdrawing foreign bodies from the ear or nostrils. It has a shank with little S-shaped prongs at the end. It is introduced into the opening and laid alongside the object; being then slightly rotated, the hooks become engaged with the object, which is then withdrawn.

Screw'ing-ma-chine'. A machine-tool for cutting screws. See SCREW-MACHINE; SCREW-CUTTING LATHE, etc.

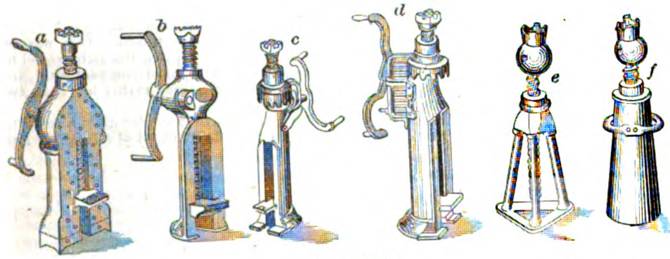
Screw'ing-ta'ble. A kind of screw-stock, used for forming the threads of screw-bolts or wooden screws.

Screw-jack. A *lifting-jack*, in which the power consists of a screw rotating in a nut in the body of the tool. See JACK-SCREW.

a, screw-jack, with wooden case.
b, screw-jack, with malleable iron case.
c, windlass screw-jack, single purchase.
d, windlass screw-jack, double purchase.
In these, additional power is obtained by multiplying gears interposed between the lever and the nut which turns the screw.
e, tripod-jack.
f, bottle-jack.
So termed from the form of the case. They are operated by a removable lever inserted in the head.

It is by no means an uncommon thing for a house to be lifted bodily from its site and removed by machinery to a new one, without disturbing the inmates, but in Chicago the operation was extended to almost the whole city, in 1867-68. The early buildings were generally erected without any regard to the laws of drainage, and eventually, as the city increased in size, the evil became intolerable. By means of screws acting under balks of timber, one of the largest hotels, known as the Briggs House, was raised in 27 days to a hight of 4 feet 2 inches above its previous level. The building had a frontage of 180 feet, a depth of 80 feet, weighed 22,000 tons, and was 5 stories high, presenting accommodation for 450 guests, none of whom were disturbed during the operation. Tremont House, another hotel of a similar size, was also raised without accident. The screws employed were about 2 feet long, $2\frac{1}{4}$ inches in diameter, with a pitch of half an inch. They worked in cast-iron sockets, and were moved by handspikes; 1,450 such screws and 600,000 cubic feet of timber were used in raising the Briggs House. A similar plan was adopted in July, 1868, at Boston, when whole streets of houses were raised in blocks of 6 houses together.

Fig. 4732.



Screw-Jacks.

Screw-key. A spanner for the articles which socket upon the mandrel-screw.

The lever of a screw-press. A form of key used with lock-faucets.

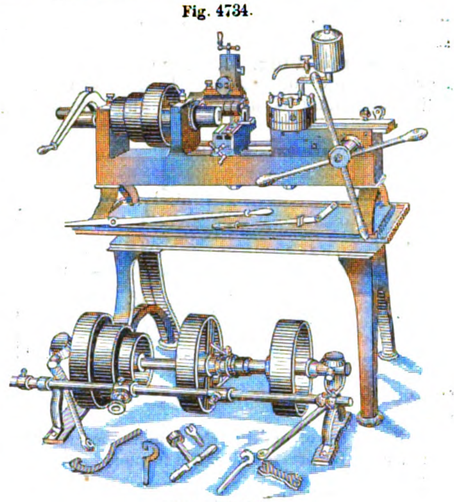
Fig. 4733.

Screw-Lock.

Screw-lock. (*Locksmithing.*) This lock has various forms, and is used for *hand-cuffs*, *fetters*, *manacles*, and also as a padlock. The essential feature is an opening bar, which is detained by a screw when in a locked position.

Screw-ma-chine'. (*Machinery.*) A machine for making from bar-iron screws and studs such as are used in a machine-shop. It is of the nature of a bolt-machine. The various sizes of dies are stocked in the circular head, and such one is presented to the blank, which rotates with the mandrel of the head-stock, as may be of the size required. It has also a rest with a transversely sliding tool-post, whereby a screw may be cut off or dressed. The rest also affords a bearing for a chasing-tool. The countershaft is shown dismounted and placed upside down upon the floor, resting upon the plates of the hangers.

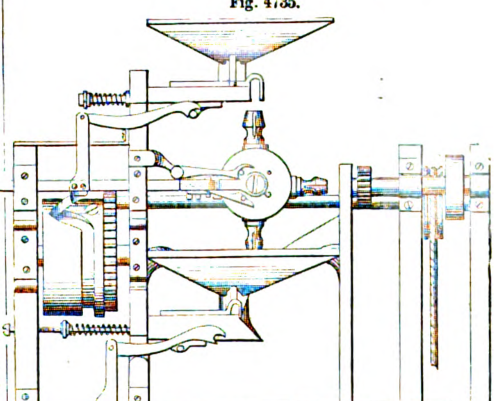
Fig. 4734.



Screw-Machine.

2. (*Wood-Screws.*) A machine or series of machines for shaving, nicking, and threading screw-blanks. The blanks are placed promiscuously in a hopper and sorted and fed therefrom to the first of the series of machines. The blank falling into a socket or being seized by a forceps, according to the mode of feed adopted, is presented to the shaving-tool, and then dropped, to be again selected and fed to the nicking-tool, the process being repeated to the thread-

Fig. 4735.

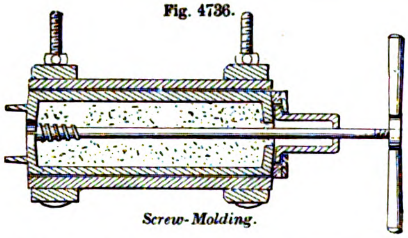


Screw-Making Machine.

er; or it is conducted through the consecutive operations.

Screw-mold'ing. 1. A process of molding screws in sand for casting. In Fig. 4736, a plain cylindrical mold is first made, and afterward the

Fig. 4736.



Screw-Molding.

thread is formed by screwing a pattern-screw through the mold.

2. A process of making sheet-metal screws for collars or caps by pressure upon a former. See Screw-cap.

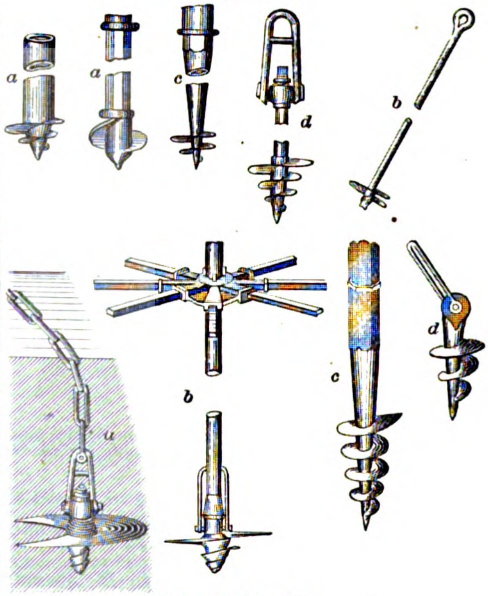
Screw-pile. A pile having a screw-thread at its lower end to enable it more readily to penetrate hard ground and to hold it firmly in position.

Screw-piles of small diameter are usually made of wrought-iron and solid; those of larger size are frequently hollow and made of cast-iron.

They were invented by Mitchell, in England, and are principally employed as foundations for light-houses, for beacons, and for mooring buoys.

They were used in the foundations of the Maplin Sand Lighthouse at the mouth of the Thames, and the Fleetwood Lighthouse, at Fleetwood, in Lancashire, both erected A. D. 1840.

Fig. 4737.



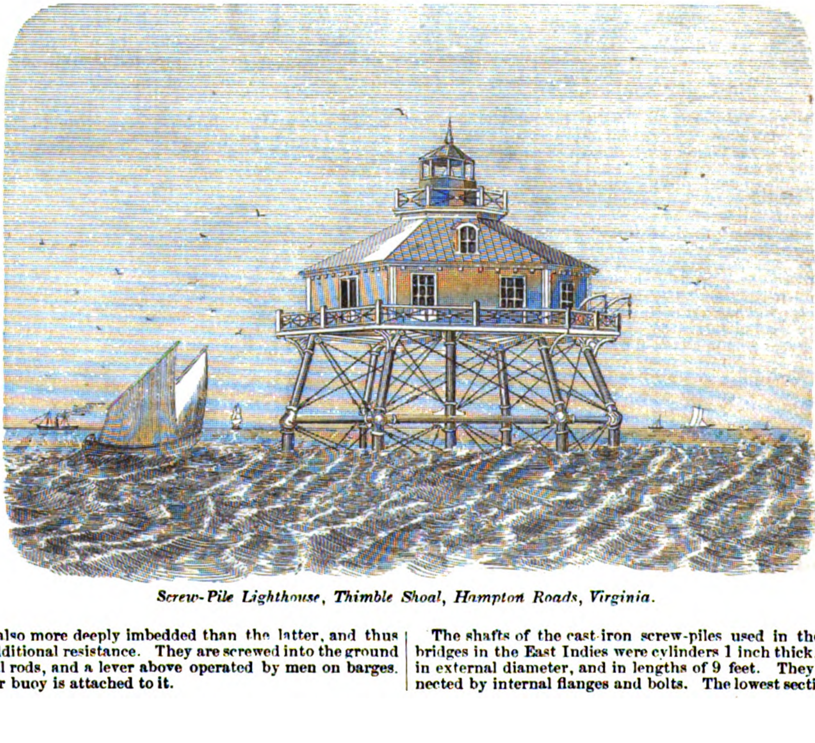
Mitchell's Screw-Pile.

a a a, mooring-pile.
b b, mode of sinking the piles into position.
c c, piles for signal, mile, or telegraph posts.
d d, piles for tethering animals, or, on a larger scale, for attaching guys or *crab* moorings.

Fig. 4738 is a view of the screw-pile lighthouse on Thimble Shoal, near the entrance to Hampton Roads. This was designed by Major Peter C. Hains, to replace the light-vessel on Willoughby Spit The shoal is of firm, hard, compact sand, and the time employed in fixing the piles was rather less than two months. The light is of the fourth order.

A mooring-pile 3 feet 6 inches in diameter gives a resisting surface equal to 10 square feet, double that of a large anchor.

Fig. 4738.



Screw-Pile Lighthouse, Thimble Shoal, Hampton Roads, Virginia.

They are also more deeply imbedded than the latter, and thus acquire additional resistance. They are screwed into the ground by vertical rods, and a lever above operated by men on barges. A chain or buoy is attached to it.

The shafts of the cast-iron screw-piles used in the piers of bridges in the East Indies were cylinders 1 inch thick, 30 inches in external diameter, and in lengths of 9 feet. They were connected by internal flanges and bolts. The lowest section formed

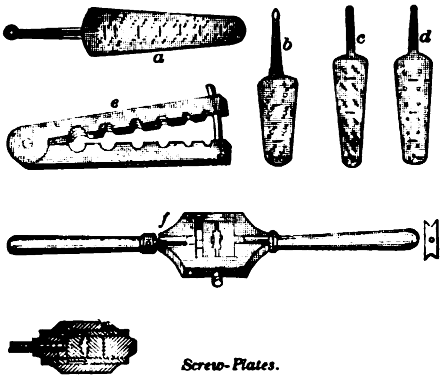
the screw of the pile, having a thread 54 inches in diameter. The cylinders were eventually filled with concrete.

These piles were screwed into the ground by means of 4 levers, each 40 feet long, and having 8 bullocks yoked to it. They penetrated from 20 to 45 feet.

Screw-plate. A steel plate having a series of holes of varying sizes, with worms and notches for cutting threads.

It is usual to bore a smaller hole on each side of that in which the screw is cut, and connect them with the latter by a slit, forming angular cutting-edges, which remove the metal, as shown at *a b c*, Fig. 4739. The wire is commonly held by a hand-vise in the left hand, and the plate operated with the right hand, several holes, of gradually diminishing diameter,

Fig. 4739.



Screw-Plates.

being employed to produce the desired thread. In some cases, for very short and small threads the holes are merely threaded, and not notched, as shown at *d*. *e* is a folding device formerly employed for cutting screw-threads; the larger holes are near the joint, so to allow greater holding power.

For screws exceeding $\frac{1}{16}$ inch diameter, it is customary to use a die-stock with movable dies; several arrangements have been adopted in these for holding and adjusting the dies; in *f* the edges of the dies have triangular notches sliding on corresponding ribs in the opening of the stock, and are held by one of the handles when screwed in. The lower figure has a pin on each side, which in one position fits a semi-cylindrical groove in the die, so as to hold it; when rotated half round, it presents a plain side to the die, permitting its removal.

Screw-post. (*Ship-wrighting.*) The inner *stern-post*, or that through which the shaft of the screw-propeller passes.

Screw-press. A press whose platen is operated by a screw, in contradistinction to one which is worked by a toggle, as in the Stanhope printing-press; by a wedge, as in some forms of oil-presses; by hydraulic pressure, as in the flaxseed-press; by a lever, as in the primitive form of cheese-press. See Fig. 1263.

The screw-press was used for coining in the reign of Henry II. of France, being introduced by Brucher. It was finally established in the French mint, 1645.

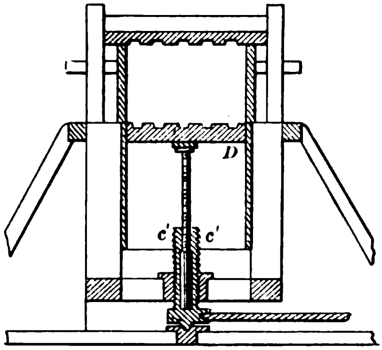
1. Screw-presses are vertical or horizontal; the screw above or beneath the platen, which is usually called a follower in this class of machinery. An understanding of the matter will be as readily attained by a few examples as by a labored description.

a. The old screw-press of the plantation or farm had a vertical screw in the upper cross member of the frame, and a follower which rose or fell, according to the direction of motion of the sweep which rotated it.

b. In another form, the screw came up from below and left the top of the box more clear for charging. In the illustration shown, the screws *C C* are in duplicate and are actuated by the same gearing.

In Fig 4740, the follower *D* is attached to the smaller screw, which works axially in the socket-thread of the larger screw. The latter passes through the nut in the sliding-frame, and is stepped in a metallic block. The revolution of the lever causes the hollow screw *c′ c′* to rotate in the lower bar of the frame, and thus lower or raise the box, according to the direction in

Fig. 4740.

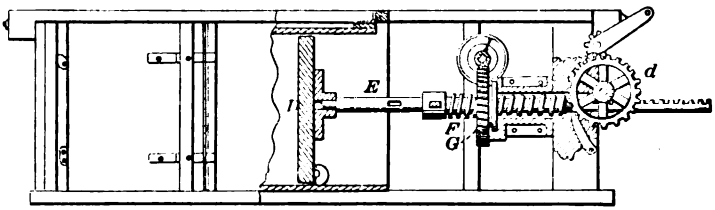


Screw-Press.

which the lever is moved. The threaded stem *c* at the same time rotates in the sleeve-screw *c′*, and raises or lowers the follower *D*. Thus the follow-block and the press-box move simultaneously and in opposite directions. See BALING-PRESS; COINING-PRESS, etc.

***c. Horizontal screw.* In the example, the follower can be operated by a slow or by a quick motion. The slow motion arises from a hollow screw-spindle *F* which screws into a worm-wheel *G* gearing with a worm. A rod *E* passing through said screw-spindle and connected with it by a key unites it with the follower. The extreme end of the rod forms a toothed rack which gears in a pinion *d*; and if the key which unites said rod with the screw-spindle is withdrawn, the pinion and rack form the quick motion for the follower, which can be used independently of the slow motion.**

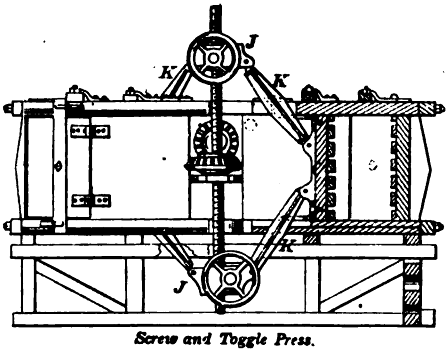
Fig. 4741.



Horizontal Screw-Press.

The press has a slow, powerful motion when compacting the bale: a quick retraction to free the bale and to open the chamber for another charge.

Fig. 4742.

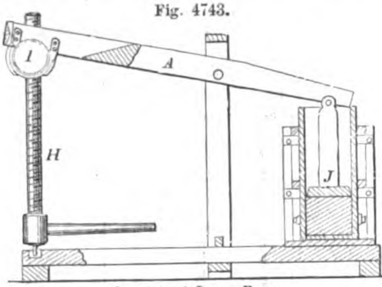


Screw and Toggle Press.

d. Screw and toggle. The revolution of the right and left hand screw draws together the heads *J* and expands the toggles *K*, forcing the followers toward the platens of the press.

e. Screw and lever. The lever is connected to the follower at one end, and has a cylindrical nut at the other, which rocks in bearings at the other end of the lever, and is engaged by a screw

Fig. 4743.

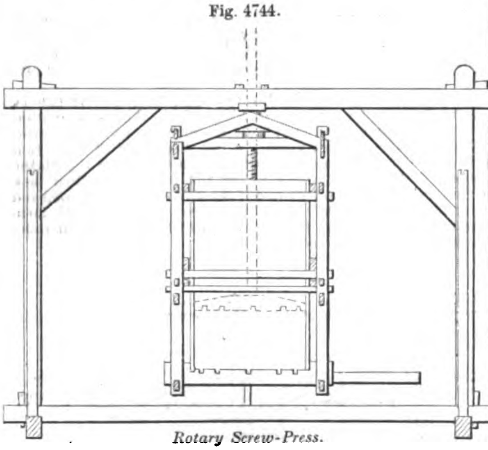


Screw and Lever Press.

which is stepped in the frame. The mule is hitched to the end of the sweep, and as he walks around, the nut *I* climbs (or sinks) on the screw *H*, tipping the lever *A* and depressing or raising the follower *J* in the box.

f. The *rotating press.* As the box rotates, the vertical screw feeds through its nut and depresses the follower. Rotation in the other direction raises the follower.

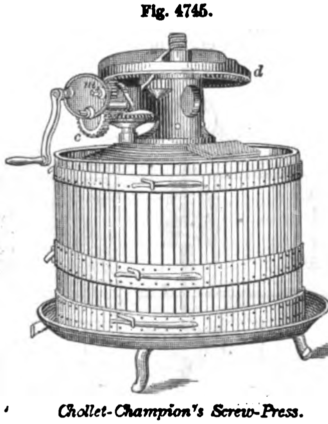
Fig. 4744.



Rotary Screw-Press.

Chollet-Champion's screw-press (French) has three arbors to which the crank can be applied, each producing a different velocity of movement in the platen. The upper two of these are the axles of pinions which can be thrown into gear with a

Fig. 4745.



Chollet-Champion's Screw-Press.

larger wheel *c* below them; the third is the axle of this larger and lower wheel itself. Upon the same arbor with this wheel is a bevel-pinion which engages a large horizontal wheel *f* correspondingly geared. The vertical arbor of this horizontal wheel carries a pinion which acts on an internal gearing in the last wheel *d* of the series, which is the nut applying the power to the platen. The base of the construction carrying this system of gearing is firmly secured to the platen, and the whole apparatus rises and falls with the movements of the press.

The smallest of the pinions to which the crank can be directly applied has 9 teeth, and the larger one 15. The wheel *c* into which these pinions gear has 45 teeth. The bevel-pinion has 10 teeth, and the bevel-wheel which it actuates 42 teeth. The pinion on the vertical axis of this wheel has again 10 teeth, and the internal gearing 65 teeth. The length of the crank is 13 inches, the diameter of the screw 4 inches, and the distance between the threads about an inch.

The force is applied first directly to the large upper wheel *d*; then by placing the crank on the axis of the lower vertical wheel *c*, which, by the conical gearing and the gearing of the internal pinion and the wheel *d*, gives one turn to the nut of the press for 27 turns of the crank. For a greater power, the crank is placed, as seen in the cut, on the axis of the 15-tooth pinion, which gives one turn of the nut to 81 of the crank. As the last resort, the crank is transferred to the axis *m* of the 9-tooth pinion, which gives one turn of the nut to 136½ of the crank. A pressure of 32 pounds on the 9-tooth pinion is equal to 50 tons on the surface of the body compressed.

Fig. 4746.

Bookbinder's Screw-Press.

2. A small stitching-press employed in attaching the head-bands, etc., to books. It consists of two plain jaws, through which guide-pins pass near each end; their distance apart is adjusted by means of a central screw. See also FLY-PRESS; COINING, etc.

Screw-pro-pel'ler. A spiral blade on an axis parallel with the keel of the vessel, and revolving beneath the surface of the water, usually at the stern of the vessel.

Screws have been used at bow and stern; at mid-ships, over the keel, or alongside; twin screws at each side of the dead-wood at the stern.

In the early applications of the screw as a propeller it consisted of a spiral blade, which made one convolution around its stem. Then two half-convolutions of a double-threaded screw were used. Since that time the tendency has been to reduce the length of the spiral.

We find notices of the suggested or experimental use of the screw-propeller by Hooke, 1680; Duquet, 1727; Pancton, 1768; Watt, 1780; Seguin, 1792; Fulton, 1794; Cartwright, 1798; Shorter, 1802.

The idea of propelling vessels by a screw in lieu of oars is mentioned in the "Machines et Inventions approuvées par l'Académie Royale des Sciences depuis 1727 jusqu'à 1731."

Franklin suggested the same thing.

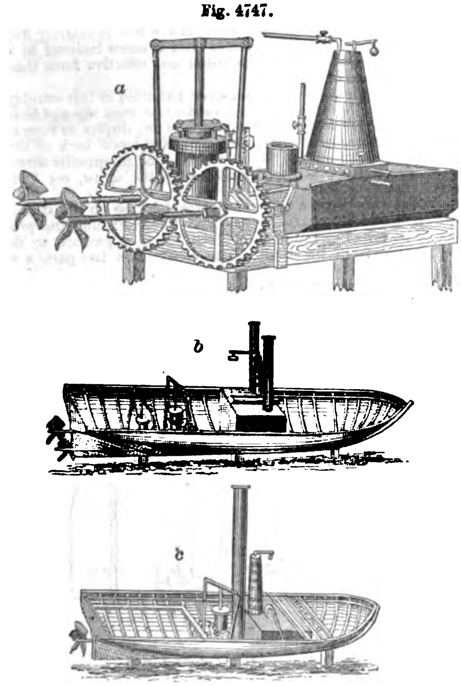
Lyttleton's English patent, in 1794, for an "aquatic propeller" consisted of a screw of one, two, or more threads wrapped around a cylinder, and revolving in a frame placed at the head, stern, or side of a vessel.

The credit of the first application of the screw-propeller for marine propulsion is undoubtedly due to Colonel John Stevens, of Hoboken, N. J. In 1804, he constructed a boat with twin screws, which "attained a very considerable speed." The machinery of this boat (*a*, Fig. 4747), which was 50 feet in length, is still preserved in the Stevens Institute of Technology at Hoboken. The boat itself is shown at *b*.

In 1844, this machinery was placed in a vessel modeled on the lines of the first boat, which, in the presence of a committee of the American Institute, it propelled at the rate of 8 miles an hour.

In 1806, he built a second and larger boat called the "Phœnix," with which he made a successful trip

Fig. 4747.



Stevens's Propeller, 1804.

to Albany in August, 1807, but a few days after that of Fulton, in the "Clermont." This, in which a single screw was employed, is shown at *c*.

Stevens navigated his propeller by sea to the Delaware, as Chancellor Livingston had obtained a patent for the navigation of the Hudson by steam. See Propeller.

F. P. Smith, a farmer, of Romney, England, made a model boat in 1834, in which was a stern screw-propeller driven by a spring. Smith's patent was granted May 31, 1836. Though his claims were more extensive, the actual novelty of his invention seems to have been placing the screw in an open space in the dead-wood (see Fig. 3973). He constructed a boat of 10 tons burden, with an engine of 6 horse-power, which was tried on the Paddington Canal, the river Thames, and, the next year, along the coast.

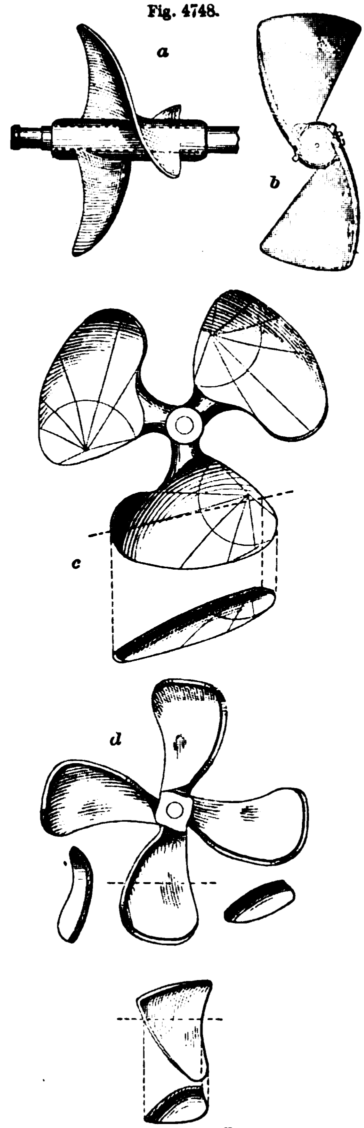
The "Archimedes" was constructed by the help of the Messrs. Rennie, in 1838. She was 155 feet long, 237 tons burden, 90 horse-power. The screws were 5 and 7 feet in diameter, the lengths 7½ and 8 feet.

In 1842, the "Rattler" was built, to determine the best proportions of the screw, and the "Alecto" was built on the same lines, and with paddle-wheels, to compare the modes of propulsion. The propeller was preferred, and soon had an important place in the British navy.

Captain John Ericsson's English patent is dated July 13, 1836, for a propeller containing several blades or segments of a screw, the twist of which was determined in accordance with the principle now usually adopted. His propeller, the "Francis B. Ogden," was tried in April, 1837, and in May of that year was used in towing an American packet, the ship "Toronto," of 700 tons burden, to sea; 4½ knots an hour against wind and tide.

Ericsson's second vessel, the "Robert F. Stockton," was built by the Lairds of Birkenhead, and launched July 7, 1838. This vessel was built for Captain Stockton, of the United States Navy. She crossed to the United States in 1839, and was purchased by the Delaware and Raritan Canal Company. Captain Ericsson subsequently built the propeller "Enterprize." He was the first to couple

Fig. 4748.



Screw-Propellers.

the engine directly to the propeller-shaft. "It will thus be seen that Captain Ericsson accomplished for the screw-propeller in America and in England what Fulton did for the paddle-wheel in the former and Bell in the latter country, namely, its practical introduction." — Woodcroft.

Several years before screw-propulsion had assumed any commercial importance in England, the carrying-trade on our lakes was, to a great extent, conducted by screw-vessels. Already, in 1843, the Ericsson

line of screw-steamers was in full operation between Philadelphia and Baltimore, running through the Delaware and Chesapeake Canal.

Rennie proposed to make the screw spiral instead of helical; the form being generated by winding an inclined plane around a cone or spire. This propeller had two blades on a cylindrical hub, and strikingly resembled a shark's tail (*a*, Fig. 4748).

b shows Hancock's two-bladed screw. The blades are removable.

Bourne prefers three-bladed screws, and gives the following data: —

The area of the circle described by the extremities of the blades should have one square foot for every $2\frac{1}{4}$ square feet in the area of the immersed midship-section. The pitch of the screw should be equal to or a little exceeding the diameter, and should have about $\frac{1}{6}$ of a convolution. The pitch should increase gradually toward the leading end of the screw, and the pitch of the center be 10 per cent less than the circumference. The blades should be inclined backward a little instead of being perpendicular to the shaft, so as to produce a tendency in the water which they drive backward to converge to a point. It is assumed that this convergent tendency may balance the divergent tendency due to the centrifugal force attending the revolution; so that the two forces being in equilibrium will cause the water to be projected backward from the screw in a cylindrical column.

As the screw revolves and thrusts backward against the water, the forward end of the screw-shaft impinges forcibly against a bearing, and thereby impels the vessel. This pressure is very severe, as may be readily imagined, when it is considered that the forward pressure is driving the vessel through the water. One device for receiving this forward thrust is a number of collars or disks placed at the end of the shaft and resting in a cistern of oil, which is firmly supported in the bed-plate of the engine, or some other place sufficiently strong. Between the end of the cistern and the shaft the disks are interposed, and are free to revolve by the frictional pressure of the screw-shaft. If the end of the shaft press with such violence against the disk as to become hot in revolving against it, and engender such friction as to carry the disk along with it, then the first disk revolves against the second, and the surfaces previously engaged, no longer rubbing against each other, have time to cool, and resume their efficiency.

The screw is sometimes suspended on a short shaft, carried by a metallic frame having a rack on one side, which is engaged by endless screws for the purpose of lifting the screw for examination or repairs. See also Fig. 4751.

Maudslay's feathering-screw is so arranged that the blades, whenever the vessel is put under canvas and the screw not required, should be placed in a direction parallel with the line of the keel, and form, as it were, a portion of the dead-wood, as they cause considerable obstruction, if they are allowed to remain fixed in their position, even though they be disconnected from the engine and allowed to revolve. In auxiliary sailing-vessels not fitted with a trunk or screw-well for raising the screw out of the water, this is particularly valuable.

c and *d* are modern forms of screw-propellers, having respectively three and four blades.

The number of blades of a screw should depend on the area of propelling surface in proportion to the length of screw on the line of the keel. The width of blades is reduced in proportion to their number.

The *pitch* of a screw is the distance it should advance in an axial line by one complete revolution, provided no force be lost, as would be the case in an unyielding medium. The *rate* is the *actual* advance, and the difference or loss is called the *slip*.

The slip varies with the angle of the propeller, its velocity, and depth of immersion. The coarser the pitch, the greater the slip.

The *friction* of a screw depends on its velocity and the smoothness of finish of the material of which it is composed.

The *vibration* depends on the form and uniformity of resistance

The *thrust* of the screw is the force exerted on its shaft to propel the vessel. This thrust is generally taken up by friction-collars on the screw-shaft.

The pitch of a two-bladed screw should in general equal $1\frac{1}{2}$ diameters; a three-bladed screw, $1\frac{1}{4}$ diameters; a four-bladed screw, 1 diameter.

The actual force exerted by a screw depends, to some extent, on its depth of immersion. The *inclination* of the screw should be such as to overcome the tendency of the body of water acted upon to rise to the surface.

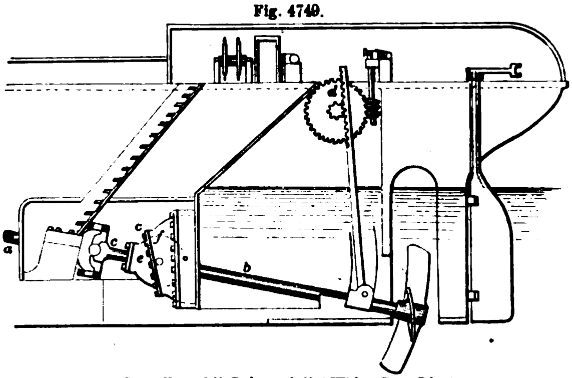
Experiments have indicated that paddle-wheels give the best result when the vessel is lightly immersed, and the screw when deeply immersed

Experiments made by the British navy tend to prove that the best results are obtained when the screw is entirely free from *back-flow* or *dead-water*; also that a screw inclosed in a pipe or box open at the ends has much less effective force than when it is not so inclosed.

Many and various devices have been patented in this country and in Europe, intended to overcome the loss from *slip* and from friction. Among these may be mentioned the duplex or reverse screw, having an inside shaft and auxiliary screw back of the one on the main shaft, the two screws moving in opposite directions. For some other modifications of the screw, see PROPELLER.

Fig. 4749 illustrates a new arrangement in use on the steamship "Britannic," of the White Star line, enabling the propeller to be raised or lowered, and still be in a position to receive motion from the shaft. The shaft is in two parts *a b*,

Fig. 4749.



Propeller of "Britannic" (White Star Line).

coupled at *c* by a universal joint; and the upward or downward movement of the propeller is effected by a pinion gearing in the rack *d* jointed to the rear part of the shaft. Water is prevented from entering the ship by a device consisting of a disk *e* through which the shaft passes pivoted within a second disk *f*, which in turn is pivoted within a casing forming part of the shaft-well, the joints being suitably packed. When the rear portion of the shaft is raised or lowered, it and the disk *e* turn on the universal joint as a center, causing the disk *f* to rotate on its axis and around the disk *e* until the propeller assumes the desired position.

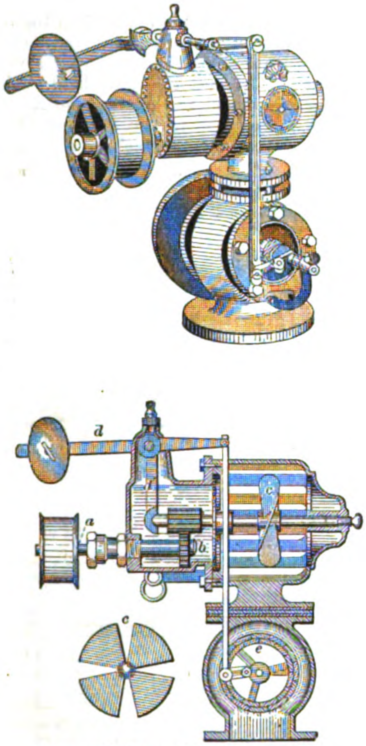
Mr R. Griffiths, of London, well known in connection with propellers, has recently proposed to employ a screw placed within a tunnel both at the bow and stern; from trials with models he concludes that an increase of nearly 50 per cent in speed can be gained with the same power.

A small boat employed at Burlington, Iowa, for crossing the Mississippi, 60 feet long, 7 feet beam, drawing 30 inches aft and 1 foot forward, and propelled by a 4-foot propeller, attains a speed of 10 to 12 miles up stream, and 15 miles down stream. She has a locomotive boiler 11 feet long, with fire-box $2\frac{1}{2} \times 3\frac{1}{2}$ feet, and 27 2-inch flues, 7 feet long The two engine-cylinders are direct-acting and vertical, of 5 inches bore and 10 inches stroke, and are fitted with circular slide-valves. The usual amount of steam carried is 80 pounds; number of revolutions, 133 per minute.

Screw-pro-pel'ler Gov'ern-or. (*Steam-engine.*) One in which the action of a screw-propeller device, working in a resisting fluid, is employed to regulate the throttle-valve. In Huntoon's (Fig. 4750), the pulley-shaft *a*, driven by belt connection with the engine, carries a gear-wheel *b* meshing with a long pinion on the shaft of a screw *c*, inclosed in a tight box filled with oil or water, and causing its rotation. The apparatus is so adjusted that when the engine is working at its normal speed, the lever *d* just balances the tendency of the propeller-shaft to move forward under the influence of the screw, and no movement of the valve *e* takes place; should the speed diminish, the weight overcomes the resistance of the screw, and the valve is opened; if the speed exceeds the regulated amount, the forward movement of the propeller-shaft, acting against the arm *d'*, causes the weight to rise, partially closing the throttle.

Screw-pro-pel'ler Steam-en'gine. A direct-action steam-engine, specifically adapted for the ro-

Fig. 4750.



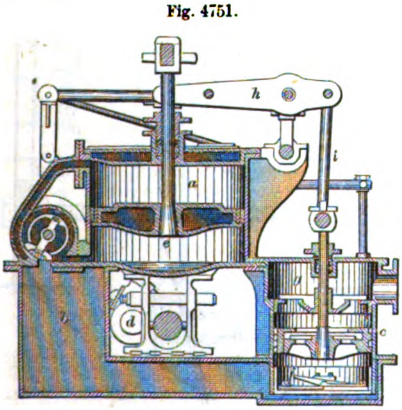
Huntoon's Screw-Propeller Governor.

tation of the screw-propeller shaft. The form of engine most commonly used for this purpose is the OSCILLATING-CYLINDER ENGINE (which see).

Maudslay's direct-action screw-propeller steam-engine was especially designed for dispensing with the multiplying-wheels, or chains and drums, between the engine-crank and the shaft of the screw-propeller, in order to give the latter sufficient speed.

The engines are ranged side by side in a line coincident with the line of the propeller-shaft, and immediately over the engine-shaft, which is concentric with the propeller-shaft, and is connected thereto by a coupling, by which the machinery and screw-shaft may be disconnected when the vessel is to be driven by sails alone.

Fig. 4751.



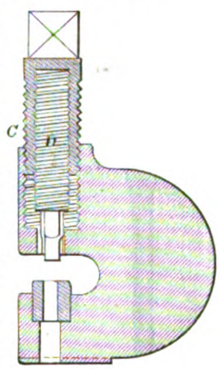
Maudslay's Screw-Propeller Steam-Engine.

The engines have a short stroke. *a* is the cylinder, supported on the upper part of the condenser *b* and on a projecting flange on the air-pump *c*. The engine-crank is beneath the cylinder, and to it is connected one of the cranks *d* of the shaft. The crank is driven by a connecting-rod from the cross-head above the piston-rod and piston *e*. The slide-valve is cylindrical, and has an oscillating motion, the peripheral depression forming a port by which the ends of the cylinder are alternately connected to the condenser *b*, while the internal ports of the valve form the induction steam-passage leading the live steam of the boiler to the alternate ends of the cylinder.

The foot of the air-pump is inserted in a flat prolongation of the condenser; and the foot-valve *f* is at the bottom of the pump. The delivery-valves in the pump are composed of annular plates, which rise and fall vertically between guides, and admit of the escape of air and water around the periphery and at the central aperture. The upper portion *g* of the air-pump forms the hot-well from which the supply for the boilers is drawn by the feed-pump, and the surplus passes off by the waste-water pipe. The air-pump is worked from the parallel motion, consisting of the working-beam *h*, connecting-rod *i*, and other associated parts, as seen in the figure.

Screw-punch. A punching device operated by a screw. In that shown, two screws *C D* are used for forcing the punch, one screwing into the first with a finer thread, so that when the larger or outer screw is turned, the inner one, being held from turning by a square shank passing through a square hole in the stock, screws into it, and therefore exerts a slow and powerful downward movement. See also PUNCHING-BEAR.

Fig. 4752.



Screw-Punch.

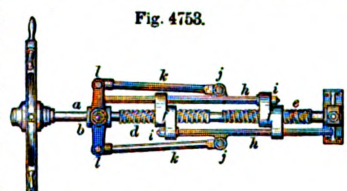
Screw-rud′der. An application of the screw to purposes of steering, instead of a rudder. The direction of its axis is changed, to give the required direction to the vessel, and its efficiency does not depend upon the motion of the vessel, as with a rudder, and the vessel may be turned on itself even when not under way.

Screw-spike. A round spike having a shallow screw-thread cut on a portion of its stem. It is driven partly home and screwed the remaining distance. See SPIKE.

Screw-steam′er. One propelled by a screw, in contradistinction to a *paddle-wheel* steamer.

Screw-steer′ing Gear. A screw on the axis of the steering-wheel may be made to act upon the rudder-head through the intervention of nuts, or nuts and rods. M'Williams's gear (English) operates by means of a right and a left hand screw *d e* on the axis *a* of the steering-wheel. *f f* are two traversing-nuts, and *h h* two traversing-rods, parallel to the spindle, and fixed respectively to the two traversing-nuts at *i i*, and each passing through a guide-eye in the other nut. *k k* are two links jointed respectively at *j j*, to eyes on the traversing-rods, and at *l l* to the two arms of the yoke. *b* is the rudder-head.

Fig. 4753.



Screw-Steering Gear.

A modified form of screw-steering gear was introduced by Reed (English). It has a similar right and left screw operating nut-blocks, which slide on parallel guide-bars. Each nut-block has a pin which engages in a slotted lug on the cap of the

rudder-head, and thus turns the rudder when the screw-axis is rotated. See STEERING.

Screw-tap. An instrument for cutting the interior thread on a hollow screw. For cutting the corresponding thread on the screw rod or bolt, a screw plate or dies are employed.

These are held in a *die-stock*, an improved form of which is shown at *a*. This is adapted to receive dies having different-sized threads, which are held by a screw; the sides of the opening being plain at one end for the ready introduction of the dies, and having ribs at the other, which fit grooves in the dies and prevent their falling out when fixed. *c d* illustrate the action of the common two-part die on the rod placed centrally between its parts. In the first the die has the same curvature as the finished screw; in the latter that of the uncut rod. In either case but a part of the cutting surface acts, and the tendency is to cut an imperfect thread.

This is partially remedied by cutting the dies of a curvature intermediate between the two.

To obviate this defect as far as possible, Sir J. Whitworth introduced the arrangement shown at *e*.

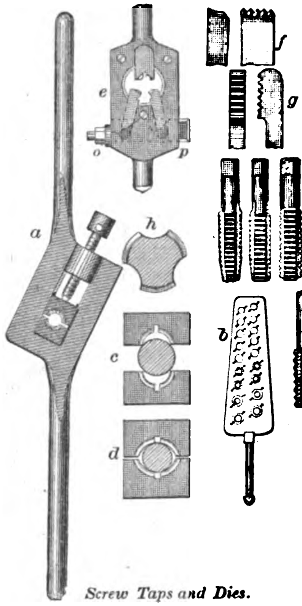
The two narrow dies act as cutters, and are advanced toward the center of the rod on which the thread is being cut by turning the thumb-nut *o*, which advances the slide-piece *p*: the broader die opposite serves principally as a guide for the thread.

f are tools for chasing exterior threads, and *g* for interior threads on work held in a lathe.

h is a section, and *i k* elevations of taps: these have a square shank fitting in an appropriate holder like the die-stock, or sometimes the die-stock itself is adapted for this purpose.

b is the screw-plate; this is principally used for small work, and has a series of screw-threaded apertures of various sizes adapted for different-sized wire.

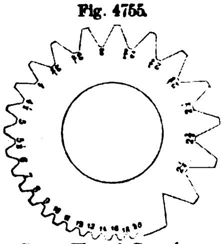
Fig. 4754.



Screw Taps and Dies.

Screw-thread Gage. A gage for giving the proper bevel to the edges of screw-cutting tools. That illustrated is adapted to the system recommended by the Franklin Institute and adopted in government establishments. The angles are of 60°, and the flat surfaces at the top and bottom of threads are equal to one eighth of the pitch.

Fig. 4755.

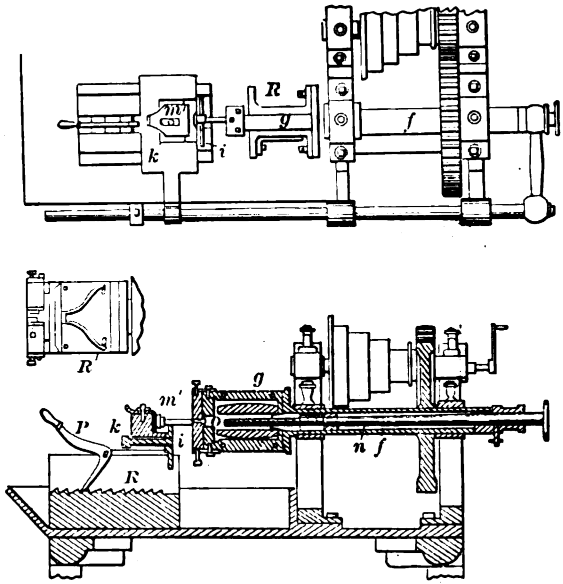


Screw-Thread Gage (one-half Size, Linear).

Screw-thread'ing Ma-chine'. A machine for cutting or chasing threads on bolts or rods. See also SCREW-MACHINE; SCREW-LATHE; TURRET-LATHE, etc.

In Fig. 4756, the screw is received in the holder *i* of the feed-head *k*, and clamped by a gage *m'*. The feed-head is advanced by the bent lever *P* engaging the ratchet-bar *R* to meet the dies which are held by die-holders *g* secured in the cutter-head *R'*. When the thread has been cut to the determined length, the end of the screw strikes the end *o* of the rod *n* within the hollow shaft *f* which rotates the cutter-head, forcing the rod back and permitting the dies to open and release the screw.

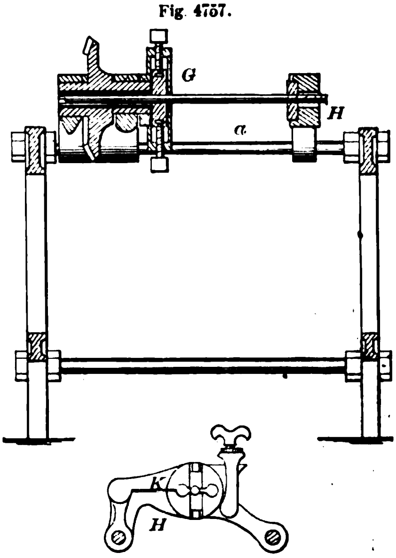
Fig. 4756.



Screw-Threading-Machine.

In Fig. 4757, the screw blank or bolt is clasped

Fig. 4757.

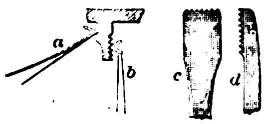


Screw-Threading Machine.

between two jaws held in the stationary head G by set-screws, and rotation is imparted by bevels, gears, and a winch. The dies are held between the pivoted jaw K and movable head H, which slides on the rod a and advances as the thread is cut.

Screw-tool. For wood-turning.

Fig. 4758.



Screw-Tools.

For soft wood: —

a, outside screw-tool.

b, inside screw-tool.

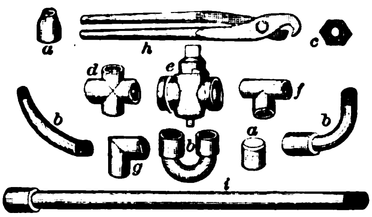
For hard wood or ivory: —

c, outside tool.

d, inside tool.

Screw-tube Fit'ting Fig. 4759 illustrates fittings for gas, water, and steam pipes of wrought-iron.

Fig. 4759.



Screw-Tube Fitting.

a a, sockets.
b b b, bends.
c, nut.
d, cross.
e, main cock.
f, T.
g, elbow.
h, pipe-tongs.
i, pipe.

Screw-valve. A faucet or stop-cock whose valve is actuated by a screw. See STOP-VALVE.

Screw-ven'ti-la'tor. A ventilating apparatus in the form of a screw, which is rotated by the passing current of heated air. It can hardly be said to be a mechanical ventilator, as it is only operated by the air in the discharge-aperture and does not drive the air through. It may be so arranged as only to rotate in one direction, and thus to impede the back passage of air while it yields to its discharge.

Screw-well. (*Shipbuilding.*) A hollow in the stern of a vessel into which a propeller is lifted, — after being first detached from the shaft, — when the vessel is to go under canvas alone.

Screw-wheel. The same as WORM-WHEEL (which see).

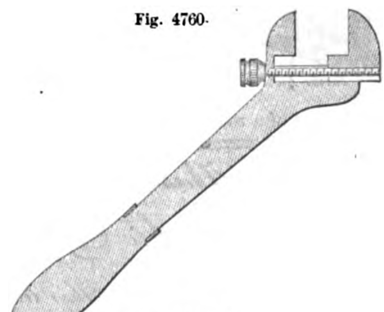
Screw-wire Fas'ten-ing. (*Shoemaking.*) Also known as *cable-screw wire.* A twisted wire for fastening soles and uppers together; a substitute for pegs or stitches. Boots and shoes made by this process have their soles fastened by a flexible wire, twisted into the form of a screw, which an ingenious machine cuts off in proper lengths and drives in without the preliminary punching which has always been considered necessary. The machine is capable of putting on five hundred pairs of soles in a day. See NAILING-MACHINE, page 1507; WIRE; WIRE-PEGGER, etc.

Screw-wrench. 1. A spanner fitting the square head of a bedstead-screw. A *turn-screw.*

2. A wrench whose movable jaw is opened and closed by a screw.

Fig. 4760 has a sliding jaw adjusted by a screw.

Fig. 4760.



Angle-Wrench.

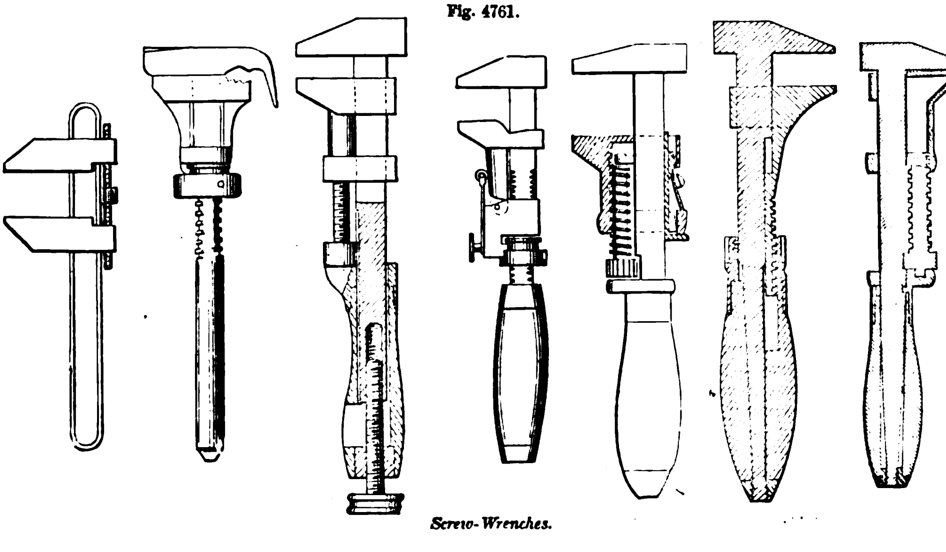
Its shape enables it to be applied to bolts in deep-seated places, not readily reached by the ordinary wrench.

Fig. 4761 shows several varieties, which do not need detailed description.

Scrib'bet. A painter's pencil.

Scrib'bler. (*Cotton and Woolen Manufacture.*) A carding-machine by which fiber is roughly carded preparatory to the final carding. A *scripling-machine.*

Fig. 4761.



Screw-Wrenches.

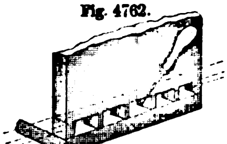
Scrib'bling. (*Cotton and Woolen Manufacture.*) The first rough carding, preparatory to the final carding.

Scrib'bling-en'gine. (*Woolen Manufacture.*) A form of carding-engine for fine, short wool, having one main cylinder, and having, in lieu of the top cards, numerous small rollers lying and rolling upon its upper surface.

Scrib'bling-ma-chine'. (*Woolen Manufacture.*) A machine in which oiled wool receives one or more preliminary cardings before passing through the regular carding-machine. It is a somewhat coarser process than carding, but of the same nature; its purpose being to bring wool to a broad, thin fleece or *lap*. It corresponds to the *breaker* for cotton. See CARDING-MACHINE.

Scribe-awl. An awl used for marking lines to be followed in sawing or cutting out work. Called also *scriber*, *scribing-awl*, *scratch-awl*.

Fig. 4762.



Scribe-Awl.

Scrib'er. A carpenter's marking-tool. A *scribe-awl*.

Scrib'ing. The fitting of the edge of a board to another surface, as the skirting-board of a room is *scribed* to the floor, being marked in position and then cut to match the inequalities.

Scrib'ing-com'pass. (*Saddlery.*) A compass with one pointed leg to act as a pivot, and one scooping edge to act as a marker. It is especially used to remove the gum on patent leather in a line for a row of stitches, and is set open to any degree by the arc and set-screw.

Fig. 4763.

Scribing-Iron.

Fig. 4764.

Scribing-Compass.

It is also used as a scribe in making a line near the edge of a strap, one leg passing along the guide-edge, while the other makes a groove on the line required.

Scrib'ing-ir'on. A scoring-tool for marking logs and casks. A *race-knife*.

Scrimp'ing-bar. (*Calico-printing.*) A grooved bar which spreads cotton cloth right and left, so as to feed smoothly to the printing-machine.

Scrims. Thin canvas glued on the inside of a panel to keep it from cracking or breaking.

Scrin. (*Mining.*) A small vein.

Script. (*Printing.*) A kind of type in imitation of writing. Called *Anglaise* by the French. There are many varieties, some very beautiful. See also SECRETARY; TYPE.

This is Great Primer Title Script.

This is Double Small-Pica Copperplate Script.

This line is English Script.

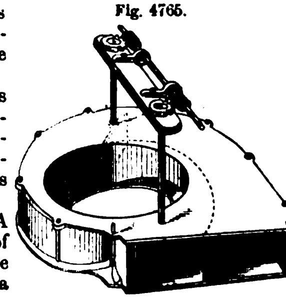
Scroll. 1. (*Joinery.*) An ornament of a form derived from, and yet distantly resembling, a partially unrolled scroll of parchment. Instruments are made for laying out scrolls and curves for stair-work, and other irregular forms. See SPIRAL, INSTRUMENT FOR DRAWING.

2. (*Hydraulic Engineering.*) A spiral or converging adjutage around a turbine or other reaction water-wheel, designed to equalize the rate of flow of water at all parts around the circumference of the wheel, by decreasing the capacity of the chute in its circuit. See TURBINE.

A double scroll is seen in the cut, the valves of each being operated by a single rod, and two worms meshing into the segment-racks of the valve-stems. Each chute supplies one half the circumference of the wheel.

Fig. 4765.

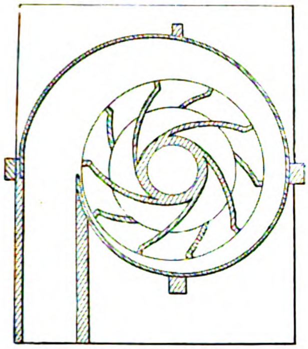


Scroll.

Fig. 4766 shows by a horizontal section the scroll diminishing in sectional area as it passes around the wheel.

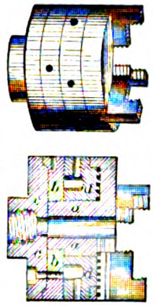
3. (*Ship.*) A piece or pieces of timber bolted to the stem in lieu of a figure-head.

Fig. 4766.



Turbine and Scroll.

Fig. 4767.



Scroll-Chuck.

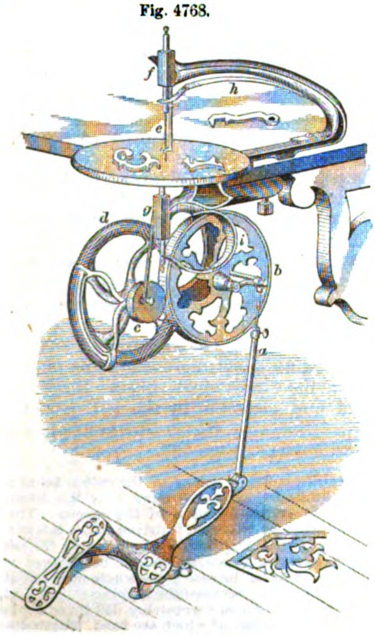
Scroll-chuck. (*Lathe.*) A device for holding and centering work in the lathe. The body of the chuck is formed of three pieces *a b c*; between these is inclosed a ring *d*, which may be revolved independently. In the face of the chuck are three radial grooves, each of which has two feathers projecting from its sides into the body of the groove; the three jaws slide freely along these grooves and feathers. A spiral on the face of the ring *d* enters a counterpart spiral on the inner ends of the jaws, so that by revolving the ring these are caused to approach or recede from the center.

Scroll-gear. A gear-wheel of spiral or *snail* form. See SCROLL-WHEEL.

Scroll-saw. A relatively thin and narrow-bladed reciprocating-saw, which passes through a hole in the work-table and saws a kerf in the work, which is moved about in any required direction on the table. The saw follows a scroll or other ornament, according to a pattern or traced figure upon the work.

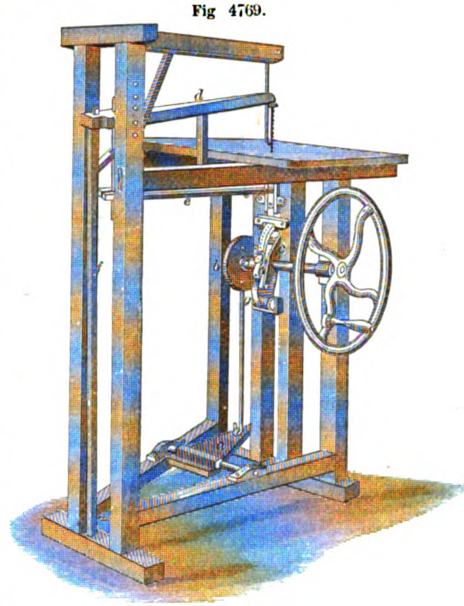
The *band-saw* is a scroll-saw, and operates continuously. See BAND-SAW.

Fig. 4768.



Fleetwood's Scrol'-Saw.

Fig 4769.



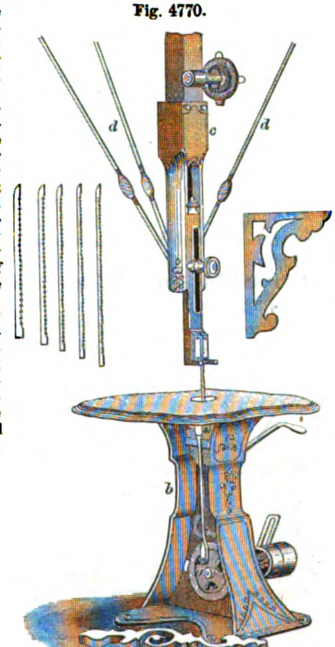
Tapley's Scroll-Saw.

The example, Fig. 4768 (Fleetwood's), is operated by a treadle connected by a pitman *a*, one part of which slides within the other, rendering it adjustable as to length to the friction-wheel *b*, which turns the smaller friction-wheel *c* and fly-wheel *d*. A pitman on the wheel *c* reciprocates the saw *e*, which is connected at each end to guides working in collars *f g* above and below the table on which the work is supported. Springs *h i* attached to the guides maintain the tension of the saw.

Tapley's is operated by a treadle *a* which imparts rotation to the wheel *b* and an arm *c* having rollers at each end. The saw is strained between the bars *d e*; the former attached to an upright wooden spring *f*. The rotation of the arm *c* opens out the endless strap *g*, which is made fast below and attached above to the saw-sash, causing the downward stroke of the saw, which is immediately thrown upward again by the spring *f*. The bar *d* may be raised or lowered to suit saws of different lengths, and the throw of the saw may be varied by the adjustment of a buckle on the strap *g*.

Fay's scroll-saw (Fig. 4770) is reciprocated by a pitman on the wheel *a*. The saw-holders move in vertical guides in the table-support *b* and hanger *c*, which is

Fig. 4770.



Scroll-Saw.

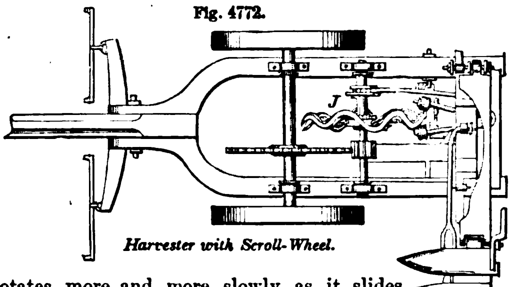
Fig. 4771

Scroll-Wheel.

steadied by tension-rods *d*. Uniform tension is secured at all points of the stroke.

Scroll-wheel. The scroll-gear acts upon the pinion, which slides by a feather on the shaft and

Fig. 4772.



Harvester with Scroll-Wheel.

rotates more and more slowly as it slides inward. It moves relatively faster as it slides outward, when the motion of the scroll-wheel is reversed.

In Fig. 4772, the scroll-wheel *J* is driven by gear and pinion from the main shaft. The friction-rollers are on the opposite sides of the scroll-wheel and impart motion to the cutter-bar.

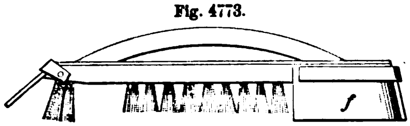
Scrow. Tanners' and curriers' clippings, used for glue-making.

Scrub'ber. 1. (*Gas-making.*) An apparatus for ridding coal-gas of tarry matter and some remains of ammonia. It consists of a tall cylinder filled with bricks, paving-stones, or coke, and having an arrangement by which a stream of water can be admitted at top and removed at bottom.

2. (*Leather.*) A machine in which leather from the tan-pit is washed to cleanse it from adhering particles of bark, hair, gum, sediment of the liquor, and other filth which it has accumulated in the various handlings during the process of tanning. *Scrubbing* is preliminary to *finishing*.

Scrub'bing-brush. A stiff brush used for scrubbing. The example has one or more flexible rubbers

Fig. 4773.



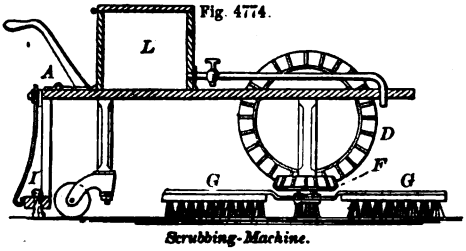
Scrubbing-Brush.

f at the end, which retain the water around the bristles.

Scrub'bing-ma-chine'. An apparatus for scrubbing floors or carpets.

In Fig. 4774, the brushes *G G* are rotated by bevel-gears *D F*; water is supplied by a pipe from the

Fig. 4774.



Scrubbing-Machine.

cistern *L*. The machine rests on rollers, is pushed forward by handles *A*, and has a swab attachment *I*.

Scrutch'er. (*Agricultural.*) A machine adapted to break, beat, or scrape flax, etc., to remove woody matter. See SCUTCHER.

Scuf'fle-har'row. (*Husbandry.*) A harrow with cutting shares instead of mere teeth.

Scuf'fle-hoe. (*Agricultural.*) A thrust-hoe having the blade in line, or nearly so, with the handle.

Scuf'fler. (*Agricultural.*) A form of cultivator used in Britain, and not distinguishable from the *cultivator* and *scarifiers*.

Scull. (*Nautical.*) *a.* A short oar rowed with one hand, two being handled by a single man, as in river-wherries and match-boats.

b. An oar used over the stern by a rocking action obliquely against the water.

c. A small boat.

Scull'ing-pro-pel'ler. See PROPELLER; OAR-PROPELLER; VIBRATING-PROPELLER.

Sculp'er. (*Engraving.*) See SCORPER.

Sculpt'ure-cop'i-er. An instrument or machine on the principle of the pantograph, for copying statuary.

James Watt was working upon a machine for taking reduced copies of busts and statues when he was attacked by his final sickness. He had produced some good specimens of his work, and had distributed them among his friends.

Scum'bling. Giving a kind of rough dotted shadow to objects in a nearly finished drawing. It is performed with a brush having some dark-brown color in it, but nearly dry.

Scum'mer. A perforated ladle or dish used in removing feculences from the surface of boiling solutions. A *skimmer*.

Scup'per. (*Shipbuilding.*) A hole or tube leading from the water-way through the ship's side, to convey away water from the deck.

Scup'per-hose. (*Nautical.*) A canvas or leathern spout on the outside of a scupper-hole, to conduct the water clear of the vessel's side.

Scup'per-leath'er. (*Nautical.*) A flap-valve of leather outside of a lower-deck scupper to keep the sea-water from entering, but permitting exit of water from the inside.

Scup'per-nail. (*Nautical.*) A short nail with a very broad, flat head; used for nailing on scupper-hose, battening down tarpaulins, fastening pump-leathers, etc.

Scup'per-plug. (*Nautical.*) A tapering block, to close a deck-scupper.

Scup'per-shoot. (*Nautical.*) A pipe to conduct deck-water to the sea-level.

Scutch. A wooden instrument for dressing flax or hemp.

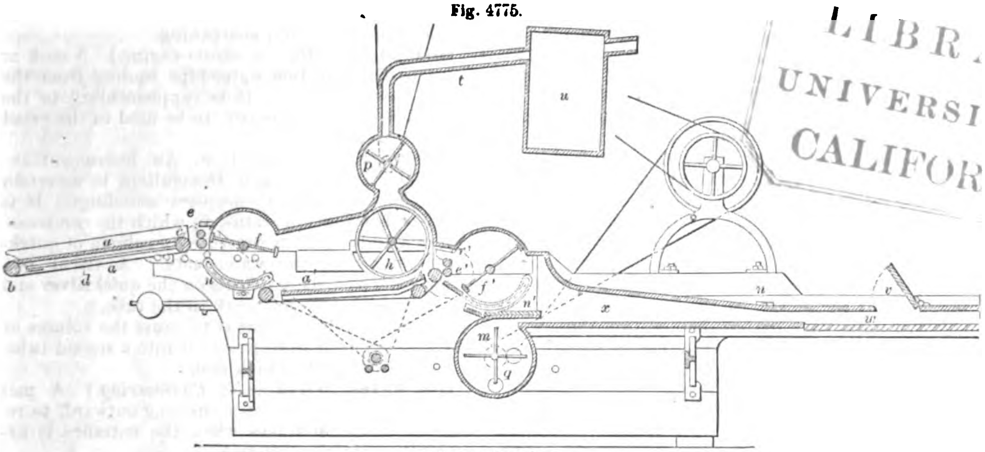
Scutch'eon. 1. (*Locksmithing.*) A cover or frame to a keyhole. A sliding scutcheon is called a *sheave*.

2. A name-plate on a coffin, pocket-knife, or other object. An *escutcheon*.

Scutch'er. (*Cotton-machinery.*) A machine, also known as a *batting-machine* or *blower*, which separates the individual fibers that have been loosened and cleansed by the *willower* or *opening-machine*. See also BATTING-MACHINE, page 251; COTTON-CLEANER, page 633.

This machine is fed by means of the cotton being spread by hand on the feed-cloth *a a*, passing over the rollers *b c*, and moving slowly in the direction of the arrows. The roller *c*, which is 3 inches in diameter, is driven at the rate of four revolutions per minute. The cloth is supported by the table *d*, and consists of a series of bands, which can be strained more uniformly than would be the case if the whole were one cloth. At *e* the cotton is caught between the nipping-rollers *e*, which present it to the batting-arm *f*, revolving 640 times a minute, and having arms, at the end of which are fixed, longitudinally, two narrow thin strips of sheet-iron. These, catching the cotton

Fig. 4775.



Cotton-Scutcher.

presented to them by the nipping-rollers, tear it off, separating the fibers from each other, and letting the dust, etc., fall through the grid *n*. The fibers thus torn asunder are again collected upon a second feed-cloth *a'*, where they are pressed together by the drum *h*, and then again caught by the nipping-rollers *e' r'*, to subject the cotton to a second batting operation at *f'*. As only the heavy impurities pass through the grid *n'*, a sucking action is provided by means of the fan *p* over the perforated compressing-drum, revolving 150 times per minute, by which the light dust is sucked up and conveyed through the channel *t* into the box *u*, where it is deposited. From the second batting-apparatus the cotton fibers are thrown into the closed channel *x*, and are driven through the same by a second fan *m q*, revolving 700 times per minute. At *w* is another grating, consisting of bars slantingly placed, and at *n v* are two doors through which the cotton is taken out.

This batting-machine can produce 500 to 600 pounds of scutched cotton in 12 hours.

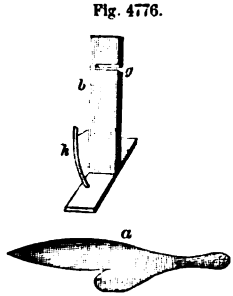
2. (*Flax Manufacture.*) A machine for dressing flax. See SCUTCHING-MACHINE.

3. (*Silk-machinery.*) A beating-engine, in which floss and refuse silk — the fibers having been previously disentangled, straightened, laid parallel, and cut into lengths — is brought to a downy condition, in which it may be treated like cotton by *carding*, *slubbing*, *roving*, and *spinning*.

The scutcher is also used to lighten up the staple and restore the downy condition thereto, after the operations of *cleansing*, *washing*, and *pressing* the fiber. From the second *scutcher* the silk staple passes to the *carding-machine*.

Scutch'ing-ma-chine'. (*Flax Manufacture.*) Scutching is an operation succeeding that of *breaking*, and similar in its operation. Its effect is to still farther separate the woody portions from the fiber, the *shives* from the *hare*, by a beating operation, which makes short bends in the stalk, as it is crimped between the bars of the descending and stationary jaws.

Fig. 4776.



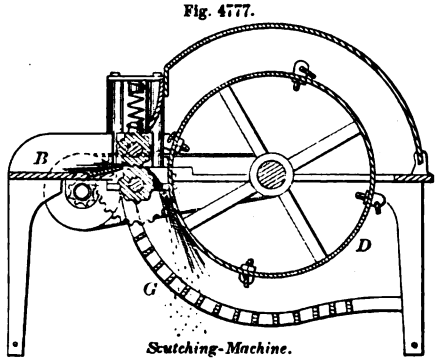
Scutching Sword and Stand.

Scutching is performed with the scutching-sword *a* held in the right hand, while with the left a handful of the bruised stems is introduced into the groove *g* in the stand *b*. A leathern band is stretched between the upright of the stand and the stake *h*, which causes the sword to rebound after each downward blow, thus easing the labor of the workman.

All remaining woody particles are removed by a blunt knife, the flax being laid across the workman's leg, which is covered with a piece of leather.

In the machine (Fig. 4777) for thrashing and scutching flax, the stalks are fed from the table *B* between two fluted rollers, the lower one of which is journaled in fixed bearings, and the upper is yielding, being pressed down by spiral springs. On passing through the rollers the stalks are subjected to the action of a series of swinging beaters pivoted in eyebolts on the

Fig. 4777.



Scutching-Machine.

drum *D*, which rotates at about 10 times the velocity of the rollers. The separated seeds drop through the slatted bottom *G*, and the bruised fiber is conveyed to an opening at the rear of the machine. See also SCUTCHER.

Scutch'ing-mill. A mill in which fiber is scutched. See SCUTCHING-MACHINE.

Scutch'ing-stock. (*Flax Manufacture.*) The part of the machine on which the hemp rests in being scutched.

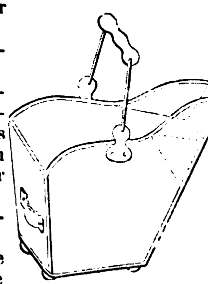
Scutch-rake. A flax-dresser's implement.

Scut'tle. 1. (*Nautical.*) A small opening in a ship's deck or side, closed by a shutter or hatch.

2. (*Building.*) A similar opening in a wall or roof.

3. (*Domestic.*) A coal-bucket.

Fig. 4778



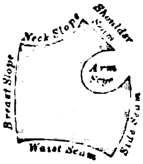
Coal-Scuttle.

Scut'tle-butt. (*Nautical.*) A cask having an opening, covered by a lid, in its side or top. It is lashed on deck, and contains the water required for immediate use.

Scut'tle-cask. (*Nautical.*) See SCUTTLE-BUTT.

Scye. The curve in the front and back, or front side and back, pieces of the waist

Fig. 4779.



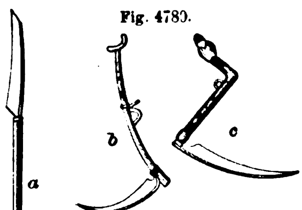
Scye.

of a garment, adapted to fit or suit the contour of the *arm* where it joins the *body* of the garment. The sleeve is adapted to fit this slope.

Scythe. (*Agricultural.*) A cutting implement having a long curved blade and a crooked handle set nearly at a right angle thereto; used for mowing grass. It is worked with a peculiar swinging motion, both hands being employed. For this purpose, the handle has two offsets or projecting pieces (*nibs*) which are grasped by the mower. The implement is of great antiquity, but was probably preceded by the sickle, as the hay crop was not an object of importance to the inhabitants of those warm countries in which the cultivation of cereals was first practiced.

"Of the scythe," says Pliny (A. D. 79), "there are two varieties, — the Italian, which is the shorter and can be handled among brushwood; and the two-handed Gallic scythe, which makes quicker work of it when employed on their extensive domains, for there they cut the grass in the middle only, and pass over the shorter blades. The Italian mowers cut with one hand only."

Fig. 4780.



Scythes.

A straight-handled scythe is used for mowing grass and weeds on the sides of ditches, and is useful in clipping hedges for those who prefer it to shears. It is not easy to give the true scythe-motion to this tool, and the title is a misnomer, though the implement has its uses. See PRUNING-TOOLS.

a is the English *hack-scythe*

b is very different from our mowing-scythes. It more resembles our brier-scythe, lacking, as it does: 1, the graceful curve and length of blade; 2, the peculiar curve of handle, which enables the mower to swing it in so extended an arc; 3, the nibs so placed as to afford a convenient grasp not liable to wrench the wrist or tire the fingers.

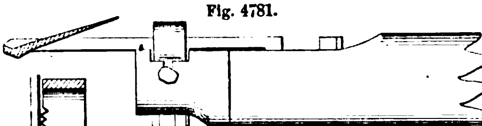
It is the scythe of the Netherlands for mowing.

The Hainault scythe *c* is the general reaping implement of Holland and Belgium. The handle is 14 inches long, with a hand-hold of 4½ inches. The blade is 27 inches in length, the point a little raised, and the entire edge beveled upward, so as to avoid the surface of the ground and the frequent use of the whetstone. It is grasped by one hand, like a reaping-hook.

Great exertions have been made to introduce this into Scotland, but without success; the reaping-hook and sickle maintained their hold until soon after the American harvesting-machine made its appearance at the International Exhibition in London, 1851. See also REAPING; CRADLE; GRAIN-CRADLE.

Scythe-fas'ten-ing. The ring and wedge or

Fig. 4781.

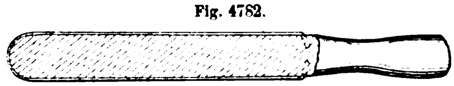


Scythe-Fastening.

equivalent device by which the tang of the scythe is clamped to the end of the scythe-snath.

Scythe-stone. A whetstone or rifle. The example has a steel wire fitted into a groove around

Fig. 4782.



Scythe-Rifle.

its edge, by means of which the edge of the scythe may be burnished after sharpening.

Sea-cock. (*Marine Steam-engine.*) A cock or valve in the injection water-pipe leading from the sea to the condenser. It is supplementary to the usual cock at the condenser, to be used in the event of injury to the latter.

Sea-gage. (*Nautical.*) *a.* An instrument invented by Drs. Hale and Desaguliers, to ascertain depths beyond ordinary deep-sea soundings. It is a self-registering apparatus, in which the condensation of a body of air is caused by a column of quicksilver on which the water acts. A viscid material, such as molasses, floats on the quicksilver and leaves its high-pressure mark in the tube.

Ericsson's improvement is to cause the volume of water thus forced in to pass over into a second tube.

b. A TIDE-GAGE (which see).

Sea-gates. (*Hydraulic Engineering.*) A pair of *dock* or *tidal-basin* gates, opening outward, to resist the action of waves when the entrance is exposed thereto during storms.

Seal. 1. A species of die having a device or motto cut in *intaglio* on its face for the purpose of stamping a device or motto in *relief* on clay, wax, or other material, while in a plastic state, or upon paper.

The signet of Taia, the Queen of Amenophis, is still in existence, in the Egyptian Museum of the Vatican.

The golden seal of Menes is in the Abbott Collection, Historical Society of New York.

The signet-rings of Thothmes III. (gold) and Amunoph III. (silver) have been preserved.

In ancient times the ring usually served as a seal. The most ancient heroes are described as wearing seals. A law of Solon, to prevent counterfeiting seals, forbade the seal-engraver to keep the form of a seal made by him. Ancient seal-rings were of gold, iron, ivory, etc. They were worn by both sexes in Greece, commonly on the fourth finger, but the fingers were sometimes loaded. Gems were frequently used, the onyx being the favorite. The modern have not exceeded the beauty of the ancient gem and cameo cutting.

Hollow cylinders of agate, amethyst, chalcedony, onyx, etc., one and a half to three inches long, and with a diameter one third the length, and engraved with arrow-head characters, are found among the ruins of Babylon, and were used as seals, by impressing upon either clay or wax. The axial hole was for a metallic rod, by which the seal was rolled upon the clay to deliver the impression. Hence the expression in Job xxxviii. 14:

"It is turned as clay to the seal,
And they stand as a garment."

Or otherwise rendered,

"It turneth round like a seal of clay,
And things stand out as though in dress."

In the metaphor, the earth itself is as a clay seal, rolling upon its axis, and all its scenery and busy life are but as images upon the face of the roller.

By inking the surface and delivering an impression, the character might be left white upon the material impressed.

A Babylonian cylindrical seal of jasper is in M. Durero's collection. It has a cuneiform inscription and the image of a winged genius in a flowing Babylonish garment. A clay seal, now in the British Museum, was probably attached to a treaty of peace between Assyria and Egypt, as it displays upon one piece of clay, side by side, the signets of the kings Sennacherib and Sabaco.

Fig 4783 shows two seals of Assyria (*a b*), and also impressions (*c d*) from two cylindrical seals.

c represents the fish god.

d is the royal cylinder of Sennacherib, found in the ruins of his palace at Koyunjik. The seal cylinders of Assyria were made of a great variety of hard stones, including agate, chalcedony, quartz, and jasper. The sides were slightly concave or convex, generally the former. It was perforated axially. The art culminated in the time of Sennacherib The seal, whose impression is shown at *d*, is equal in execution to the best Greek intaglios Besides the king and certain religious emblems, the ibex is shown upon the lotus flower. The material is of translucent green feldspar.

Fig. 4784 represents seals, a cylinder, and two tablets of the ancient Assyrians.

The materials for sealing in ancient times were terra-sigillaris (a kind of clay), cement, paste, wax, and lead.

King Ahab affixed his seal to the death-warrant of Naboth, 899 B. C.

Impressions on lead were attached to Saxon documents.

Fig. 4783.

Assyrian Seals.

Wax was first used on documents about 1213.

Magna Charta is sealed with white wax. In 1445, red wax was used in England. Tavernier mentions the use of gum-lac in Surat. A German recipe of three centuries since recommends

Fig. 4784.

Assyrian Seals, Cylinder, and Tablets.

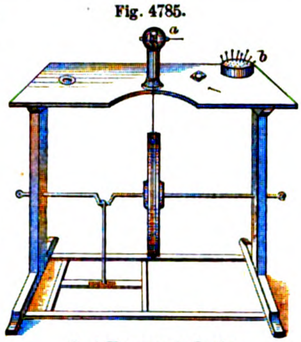
pure resin, with cinnabar, lampblack, smalt, white lead, or orpiment, according to the color desired.

An early specimen of sealing-wax is on a letter, August 3, 1554, from "Gerard Hermann" to "P. H. Von Dann," in Germany. See SEALING-WAX.

2. (*Gas-works.*) A water-trap joint, as in gas-works, where the gas is drawn or forced beneath a plate, whose lower edge is beneath the level of the water in the tar-well. See DIP-PIPE, page 705.

Seal-en-grav'er's Lathe. A table hollowed out at one side, and having a treadle connected with the shaft of a pulley, which has belt connection with the quill of the engine *a*, fastened on its upper surface. *b* is a device for holding the tools, and near it is a cap for containing diamond-powder paste. See SEAL-ENGRAVING.

Fig. 4785.



Seal-Engraver's Lathe.

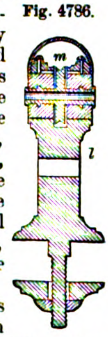
Seal-en-grav'ing. Seal-engraving was very common in ancient Babylon and other cities of Mesopotamia of that era.

The materials were amethyst, carnelian, rock-crystal, agate, bloodstone, chalcedony, onyx, jasper, serpentine, pyrites, etc.

The stones of Ethiopia, used for arrow-heads by the contingent from that country in the army of Xerxes, are spoken of as "the kind used for engraving seals." — HERODOTUS, VII. 69.

Gems, precious stones, glass, and other hard substances which do not admit the application of tools with cutting edges, are engraved either in relief or in intaglio by means of small revolving wheels charged on their edges with fine abrasive powders and lubricated with oil or water. The object to be engraved is applied to the lower edges of the wheels by the fingers, and is turned about during the process, so as to expose every part of the device successively to the action of the little wheels, which gradually produce small hollows and grooves that are, in section, nearly counterparts of the sections of the tools employed in their formation.

Fig. 4786.



Wheel-Head.

The wheels have a great variety of sizes and shapes, and are, in conjunction with the abrading powders, the only means employed to produce the device.

For engraving hard stones, the wheels are made of iron and charged with diamond powder, and are generally lubricated with *oil of brick*, and the surfaces are polished by means of copper wheels charged with rottenstone and water.

For engraving glass, similar but larger tools of copper, charged with emery-powder and olive-oil, are employed, and the polishing is effected with leaden tools charged with pumice-powder and water.

The wheels, called *tools* (*a* to *k*, Fig. 4787), have long, conical stems fitting into the hollow mandrel or *quill* of a small lathe-head or engine (Fig. 4786), mounted on a table, which is hollowed out in front, and has a light treadle for turning the engine with a steady motion. The lathe-head *l* has a conical cap to prevent access of dust, and for steadying the hand of the operator. It contains a pulley *m*, through the hollow bearings of which the quill passes. The quill is of steel, about 2 inches long and ½

Fig. 4787.

Seal-Engraver's Wheels.

inch in diameter, and has a longitudinal groove, into which a feather on the tool fits. It is a part of the lathe, Fig. 4785.

The general shape of the tool is that of a disk rounded on the edges. For cutting fine lines, the edge is sometimes made almost as thin as that of a knife, but for some purposes the tool is made nearly spherical. The tools with rounded edges cut more rapidly, and are used for removing the bulk of the material, while those with flatter edges are employed for smoothing the surface. To prevent the stem from interfering with the action of the tool in this case, it is made tapering. The tools seldom exceed $1/8$ of an inch in diameter, and are made as small as $1/150$ of an inch. Their surfaces must be smooth, as any irregularity tends to chip off pieces of the stone. The diamond powder is mixed into a paste with oil, is kept in a box, and is applied to the edge of the tool as required, being moistened from time to time with oil of brick or sperm oil to keep it from drying on the tool.

The stones are shaped to their general form by the lapidary, and are frequently set before being engraved: if set, they are inserted in a notched piece of cork or bamboo; if otherwise, they are cemented to a wooden handle. If the surface is hard and polished, it is roughened by rubbing on a steel plate charged with diamond powder and oil; if soft, on a leaden plate with emery. The outline of the design is sketched on the stone with a brass point, and the surface within this outline is sunk; the details are then sketched and sunk in succession.

A lens is mounted on the stand, through which the engraver watches the progress of his work, occasionally taking a proof with blue modeling clay, or a composition of beeswax and fine charcoal powder.

Seal'ing. 1. (*Building.*) Securing an object in a wall or other surface by means of mortar or cement.

2. (*Hydraulics.*) Preventing flow or reflux of air or gas in a pipe by means of carrying the end of the inlet or exit pipe below the level of the liquid. See SEAL; SEAL-PIPE; DIP-PIPE, Fig. 1660.

Seal'ing-press. See SEAL-PRESS.

Seal'ing-wax. A composition for securing letters and packets.

Bitumen from Asia was used among the Egyptians and Romans. Pipe-clay, or a cement of pitch, wax, plaster, and fat, was also used.

Sealing-waxes made of resin, and colored with vermilion, lampblack, white-lead, or orpiment, were made in Europe in the sixteenth century. The art seems to have been derived by the Portuguese from India, and to have reached the rest of Europe through Spain. It was long known as *Spanish wax.*

Sealing-wax has a resin for its basis, and has no wax in its composition; but as it took the place of wax as a material for sealing documents, the old name was retained.

The best is made of shellac and Venice turpentine, colored by vermilion or ivory black.

The great official seals of England, Scotland, and India are made of different colors respectively, and of various ingredients, and a great fuss is made about it.

The great seal of England is made according to a recipe preserved by the Lord Chancellor, and it makes excellent grafting-wax, as the writer knows by experiment. It comes rather high for the purpose.

The following is a good recipe: —

Melt 4 pounds of shellac; 1 pound of Venice turpentine; 3 pounds of vermilion. Incorporate by stirring, weigh into portions, and roll into sticks. Polish by exposure to a charcoal fire.

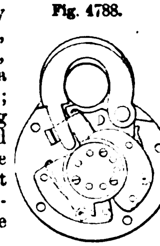
Common sealing-wax consists of resin, turpentine, red-lead.

At the Vienna Exposition were shown small sticks of variously colored sealing-wax, tipped with an inflammable compound, which, when ignited by friction, burns and fuses the wax, permitting it to be used very conveniently, without wasting or dropping, as is usually the case. The quantity in each stick is sufficient for one common or two small seals. Commenting on this, the "Technologist" says that the device is by no means new, being even older than the invention of friction-matches.

Seal-lock. A lock provided with a seal which must be ruptured in the act of unfastening, and which thus indicates the fact in case of its being improperly opened or tampered with.

In Fig. 4788, the paper seal is held down upon the plate through which the key is to pass to reach the tumbler, by a shutter hinged at one end, and, when closed, fitting within a raised frame upon the lock-plate; the shutter has a hook projecting from its free end, which is grasped by a projecting portion of the tumbler at the same instant that another portion of the same tumbler engages with the nose of the hasp.

Fig. 4788.



Seal-Lock.

The lock-bolt has two catches which simultaneously engage with or disengage from the hasp and from the seal-cover, so that a seal cannot be removed from the lock without unlocking the same.

In later locks of this kind variegated glass is employed in making the seals. These are cut into squares $\frac{1}{2}$ or $\frac{5}{8}$ inch in diameter, each containing a letter and number, a photograph having been previously taken of the sheet, and the photograph is also divided into corresponding squares.

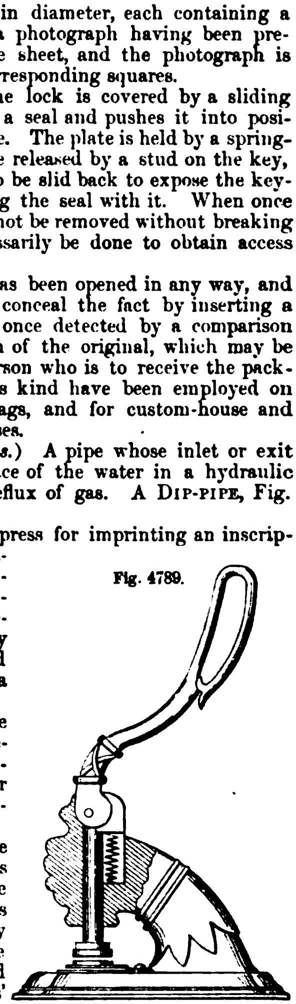
The keyhole of the lock is covered by a sliding plate which receives a seal and pushes it into position over the keyhole. The plate is held by a spring-catch, which may be released by a stud on the key, allowing the plate to be slid back to expose the keyhole, without moving the seal with it. When once in place the seal cannot be removed without breaking it, which must necessarily be done to obtain access to the keyhole.

In case the lock has been opened in any way, and an attempt made to conceal the fact by inserting a fresh seal, it is at once detected by a comparison with the photograph of the original, which may be forwarded to the person who is to receive the package. Locks of this kind have been employed on freight-cars, mail-bags, and for custom-house and various other purposes.

Seal-pipe. (*Gas.*) A pipe whose inlet or exit is beneath the surface of the water in a hydraulic main to prevent reflux of gas. A DIP-PIPE, Fig. 1660.

Seal-press. A press for imprinting an inscription or device on paper or plastic material. In the example, the handle depresses the seal by means of a cam, and is thrown up by a spring.

Fig. 4789.



Seal-Press.

A fly between the die and the bed prevents the surrounding parts of the paper from receiving an impression.

Seal-skin. The skin of the seal is light, but of a close texture, and makes a very dense, heavy leather. It is made into black enameled leather for ladies' shoes, for hunting and riding boots and knapsacks. The pelt is also largely applied for caps and fur clothing. The long hairs are pulled out, leaving the short, fine, soft fur, which is thick on the skin; after which the fur is dyed.

Seam. 1. (*Shipwrighting.*) The space between

two planks of a ship's skin, filled with oakum by *calking*.

2. (*Fabric.*) The junction of two widths of fabric united by sewing.

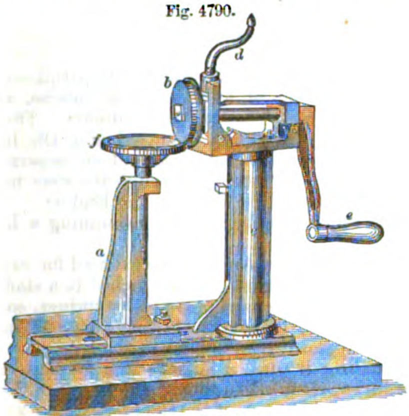
3. (*Mining.*) *a.* A narrow vein or layer.

b. A horse-load.

Seam-ham'mer. (*Coppersmithing.*) A creasing-hammer for flattening seams and joints.

Seam'ing-ma-chine'. A machine for forming the joints at the edges of sheet-metal plates. In that shown, Fig. 4790, this is effected by placing the work on a *former* at the top of a mandrel in the

Fig. 4790.

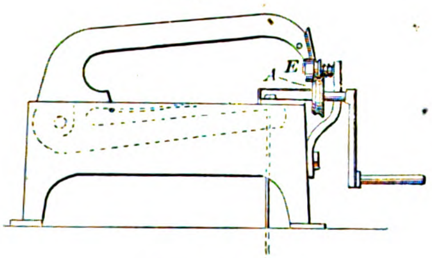


Seaming-Machine.

horizontally adjustable shaft *a* and bringing down upon it the rotating head *b*, journaled in a casing, the upper part of which is hinged, on top of the standard *c*. A screw *d* forces the head tightly down on the seam, and by turning the handle *e* it is caused to rotate, carrying with it the former *f*, pressing the two parts firmly, and closing the seam. See also DOUBLE-SEAMING MACHINE; ROOF-SEAMING MACHINE.

In Fig. 4791, when the cylindrical part of the can is formed and the flange turned upon the bottom, the seam is completed by the grooved rotary-

Fig. 4791.

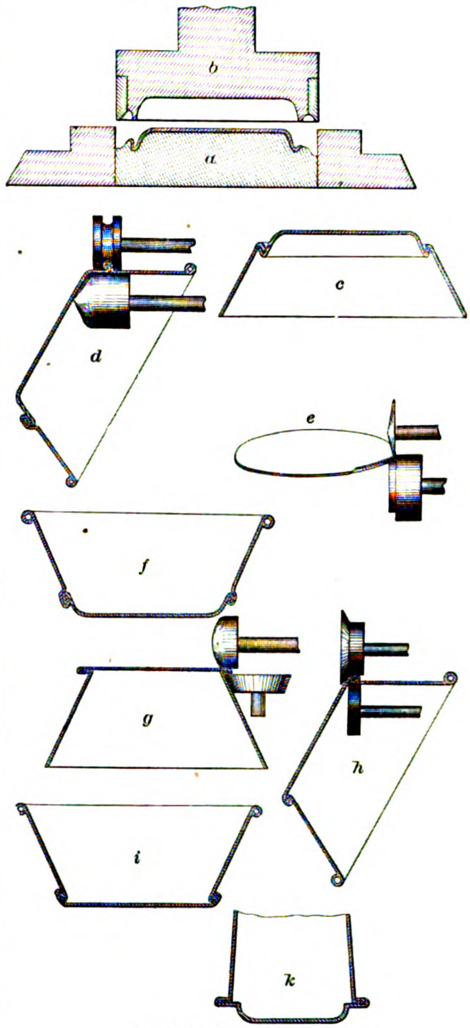


Seaming-Machine.

roller *A* and adjustable rotary pressure-head *E*. The pressure-head is drawn downward by a treadle and raised by a spring.

In Fig. 4792, the bottom of a pan or other vessel is struck up between the dies *a b*, and united to the body by a single pressure between two rollers of proper shape to close the seam, forming the joint shown at *c*. Other methods of performing this operation, and the seams produced thereby, are seen at *d e f g h i k*. See also STAMPING-MACHINE; STRIKING-MACHINE.

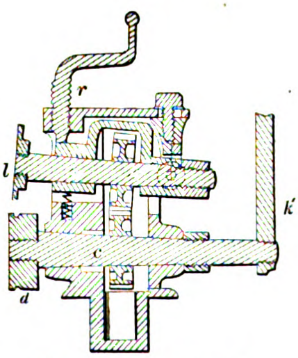
Fig. 4792.



Seaming Sheet-Metal Ware.

Fig. 4793 is another form of seaming-machine, in which the upper axis, carrying the flanging-roller *l*, is depressed by turning the hand-screw *r*, depressing the tin plate into the groove of the roller *d*. The axis *c* is then turned by the handle *k'* spinning up the edge of the tin plate as it passes between the two rollers.

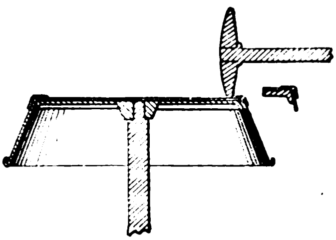
Fig 4793.



Tinman's Seaming-Machine.

Seam'ing-tool. A tool for joining or working the edges of sheets of metal.

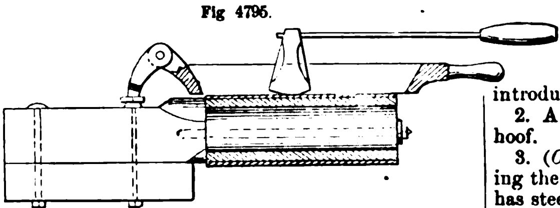
Fig. 4794.



Seaming-Tool for Pans.

(See SEAMING-MACHINE.) Fig. 4794 is a machine for deflecting the bottoms of vessels made of sheet-metal. The inverted pan is laid upon a disk which has a flat central depression and a marginal flange; against the edge of the latter the bottom of the pan is deflected by the rotary head.

Fig 4795.



Tool and Holder for soldering Seams of Sheet-Metal Ware.

Fig. 4795 is a device for seaming sheet-metal cans. The metallic cylindrical former receives the sheet-metal cylinders to be soldered; an adjustable solder-trough clamps the suture, and a soldering-iron passes along to complete the operation.

Seam-lace. (*Fabric.*) A narrow stuff used by carriage-makers to cover seams and edges.

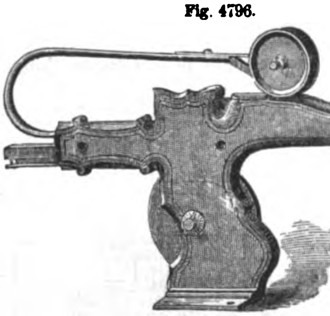
Seam-press'er. 1. (*Husbandry.*) A heavy roller to flatten newly plowed land.

2. (*Tailoring.*) A sadiron or goose, to flatten seams.

Seam-roll'er. (*Boot-making.*) A burnisher, or rubber, for flattening down the edges of leather where two thicknesses are sewn together. Machines for seam-rolling have a jack or holder for the boot-leg and a reciprocating rubber to flatten the seam.

Seam-rub'ber. The roller is attached by the curved spring to a sliding bar, which is reciprocated in ways in the cross-head through suitable gearing

Fig. 4796.



Seam-Rubber.

communicating with the rotary shaft and pinion. The seam to be pressed or rubbed is adjusted over the longer arm of the cross-head beneath the roller.

Seam-set. 1. (*Tin-working.*) A punch used by tinmen for closing the seams prepared on a hatchet stake. (See STAKE.) The face has a groove which shuts down the edges, usually upon a wire.

2. (*Shoemaking.*) A tool for flattening the seams of boots, shoes, or harness.

Fig. 4797.

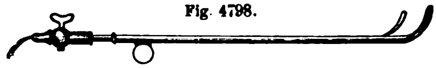
Seam-Set.

Sear. (*Fire-arms.*) The pivoted piece in a gun-lock, which enters the notches of the tumbler to hold the hammer at full or half cock, and is released therefrom by pulling the trigger in the act of firing.

The *half-cock* notch is made so deep that the sear cannot be withdrawn by the trigger.

Search'er. 1. (*Surgical.*) An instrument for

Fig. 4798.



Lithotomy-Searcher.

feeling after urinary concretions. It partakes of the character of a catheter, a douche, and a forceps. The staff is a cannula. The bent ends are joined in introducing the instrument into the urethra, and are separable to grasp the stone. Through the stem may be introduced liquids to wash out the bladder.

2. A kind of probe used in examining a horse's hoof.

3. (*Ordnance.*) An instrument used for examining the bore of a gun. It is attached to a staff, and has steel points pressed outward by springs, so as to enter cavities, if any exist, when pushed in and drawn out and turned around in the bore.

Sear'ing-ir'on. A farrier's iron for cauterizing.

Sear-spring. The spring which causes the sear to catch in the notch of the tumbler.

Sea'son-ing Tub. (*Bakery.*) The trough in which the dough is set apart to rise.

Seat. 1. (*Machinery.*) The part on which another thing rests, as a valve-seat.

2. (*Saddlery.*) *a.* The broad part of a saddle, on which the rider sits.

b. The top piece on a gig saddle.

3. (*Furniture.*) The flat portion of a chair or sofa, to support the person.

Fig. 4799.

Reversible Seat.

Reversible seats are used for concert and school rooms, for railway cars and in some other places. The seat is usually fixed and the back connected to segments, which are pivoted to the arms, the pivots forming the centers of oscillation when adjusted.

4. The lower or fixed plate of a pair of bellows.

5. (*Ordnance.*) That part of the bore of a chambered piece of ordnance at which the shell rests when rammed home.

Sea-wall. (*Hydraulic Engineering.*) A revetment along a line of coast, or the bank of a water-course.

A sea-wall may form one or more sides of a harbor, as in the case of the Heptastadium of Alexandria, the moles of the Pireus and Rhodes, of Civita Vecchia, Ostia, and Antium, as well as those of many modern ports, especially in Europe, whose small rivers afford but narrow refuges.

The Roman embankments of Essex and Lincolnshire, in England, were steep mounds of earth, defended by rows of

piles, the intervals between the rows being filled up with chalk.

Modern embankments on the estuary of the Thames consist of three strata. The rise of tide is 10 feet, and the lower or main portion of the work is made with a base of 5, to 1 vertical The top width of this portion is 20 feet, and on it rests the *outburst* bank, 5 feet high and 8 feet wide at top; having a slope of $1\frac{1}{2}$ to 1; thirdly, the *swash* bank, $2\frac{1}{2}$ feet high, and the same width at top.

The embankments are *pitched* with stone on a solid facing of clay, in positions much exposed, while in others the surface is covered with clay and gravel where it is washed by the water, the upper slope being turfed or protected by a growth of couch grass, ray grass, or lucerne.

Shore defenses are of four kinds: —

1. Artificial constructions which break the force of the waves before they reach the shore.

2. Those which consolidate and elevate the shore itself, so as to enable it to resist the action of the waves.

3. Those which make or assist the accumulation of sand or shingle upon the shore.

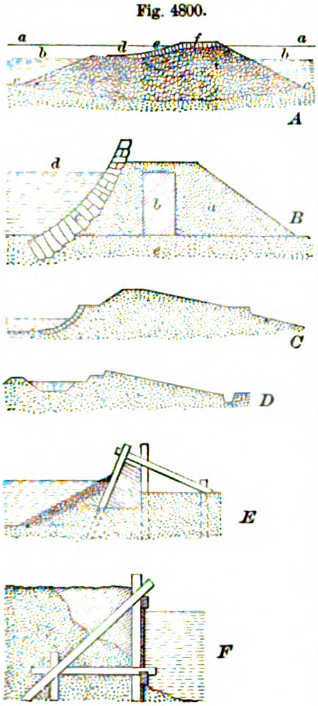
4. Permanent breakwaters, which act as islands in the offing and exclude the waves.

Of the first description *were* the cones of Cessart, placed off Cherbourg. Being destroyed, a breakwater of coursed masonry on a bank of *pierre perdue* was substituted.

Of the same description also are the moored crates of timber, through whose interstices the water passes, the timbers breaking the force of the waves See BREAKWATER.

Of the second description are the dikes of Holland and of France. These are *sea-walls*, and belong to this article

Fig. 4800.



Sea-Walls.

A, Plymouth breakwater.
B, sea-dike with facing wall and core.
C D, inclosure of Zuid Plas, near Rotterdam, Holland.
E, polder bank, Holland.
F, Havre sea-wall.

Of the third description are groins or timber erections, which are common on the sandy coasts of England and France. See GROIN.

The works of Brémontier in the Landes of Bordeaux are also of this character, though they are rather those of the planter than the constructor. His devices were eminently worthy of the engineer on the principle of Leupold's maxim, —

"Artis est naturam imitare."

Of the fourth description are the solid breakwaters of Plymouth, Cherboprg, Cette, at the mouth of the Delaware, Buffalo, and elsewhere.

Sea-walls are made in many places to protect harbors or to save the land from encroachment. When faced with coursed masonry, they may have the form shown at *B*.

a is an earthen embankment; *b*, a solid wall or core of puddle; *c*, a facing-wall of masonry; *d*, the high-water level of the sea or bay; and *e*, the natural bed. The form of the front wall must be adapted to resist the action of the waves, and the embankment must have an internal slope, according to the nature of the materials of which it is composed; for ordinary materials, a base of $1\frac{1}{2}$ to a perpendicular hight of 1 will insure the necessary stability and firmness.

If the entire embankment be formed of loose stones, with occasional facing only of laid masonry, as in the case of the celebrated breakwater at Plymouth, a form of less steepness must be adopted for the sea-face of the embankment.

A, Fig. 4800, is a section of the Plymouth (England) breakwater. The line *a a* shows the level of high-water spring-tides; *b b*, low-water spring-tides; *c c*, original bottom, varying from 40 to 45 feet below low-water mark; *d*, the foreshore; *e*, sea-slope; *f*, top, 45 feet wide. The mass of the work is composed of limestone, from the Overton quarries, distant 4 miles from the spot. The stone is raised in blocks varying from $\frac{1}{2}$ to 10 tons and upward in weight, which are promiscuously thrown into the sea, care being taken that the greater number of the large blocks are thrown upon the outer or sea slope, and that the whole are so mixed together as to render the mass as solid as possible, the rubbish of the quarry and screenings of lime being flung in occasionally to assist the consolidation of the materials. The form of the outer slope, below low-water line, has been effected by the action of the sea, and is ascertained to be at from 3 to 4 feet of base to 1 of perpendicular altitude. From low water upward the work has been set artificially and inclined at 5 to 1. The inner slope next the land is nearly 2 feet base to 1 altitude. The foreshore, shown at *d*, which is from 30 to 70 feet wide at different parts of the work, rises from the toe of the slope to a hight of 5 feet above low water at its outer extremity, and serves to break the waves before they reach the main work; thus diminishing their force, and, at the same time, preventing the recoil of the wave from undermining the base of the slope.

No other country in the world has so stern a contest to wage with the waters for its existence as Holland. Many thousands of square miles of tillable land have been reclaimed, and are only maintained by vigilance in the preservation of the *dunes* or banks of sand which oppose the waters of the ocean and the large estuaries and rivers of the country. The conformation of these is indicated by the illustrations, one of which (*D*) shows a sea-wall, and the other (*C*) one of the subordinate embankments, whereby the interior water-courses are lifted above the level of the country they traverse.

The materials of the Dutch sea-walls or *dikes* vary with the facilities, situation, materials, exposure, slope, etc.

Piling; double sheet-piling, with interposed puddle or rubble; earthen embankments, with or without walls of puddle. to render them water-proof; bundles of reeds, fascines, or gabions, laid in cross tiers with strata of soil, and secured by stakes or masonry.

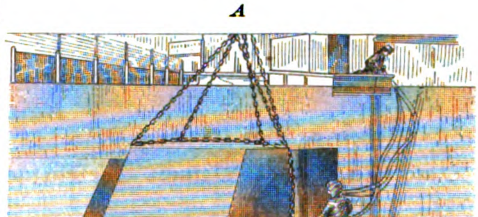
Another form of sea-wall *E* is extensively used in the banks of the polders of Holland. It consists of a double row of sheet-piling inclosing a *puddle dike* of retentive soil. The foot is protected by an apron of rubble.

At Havre an embankment of earthwork is formed behind a vertical inclosure of sheet-piling, as shown at *F*. The piles of the face are fastened by diagonal ties to the rear row of piles. The foot is protected by rubble or coursed masonry, according to the character of the ground, the exposure to currents, etc.

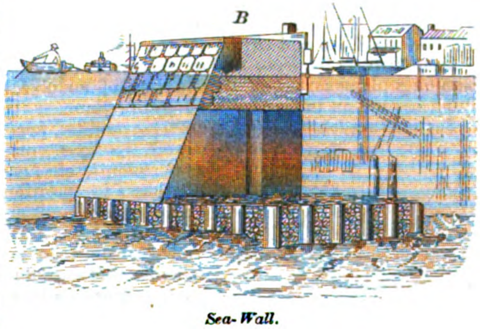
In Fig. 4801, *A B* illustrates the sea-wall now being built along

Fig. 4801.

A



B



Sea-Wall.

the water-front of New York City. Beyond this, piers will project into the stream. In the execution of the work the old wooden docks are removed, and the bed of the river dredged until solid bottom is reached. Piles are then driven, for the width of 27 feet, sawed off to a uniform depth below low water, and the interstices between them filled up to within two feet of their tops with stone thrown over from barges. Upon this a layer of concrete is spread by divers to the level of the tops of the piles. The concrete is composed of 1 part of Portland cement, 2 sand, 4 crushed stone; and, when it has set, blocks of the same are laid upon it to form the wall. These blocks are molded; the larger blocks designed for the front of the wall average 36 tons in weight, and batter 2½ inches to the foot on the outer or water side; square, smaller blocks are used for backing. The upper part of the wall has a granite coping whose exposed portions are dressed.

The sides of the large concrete blocks are grooved to receive a chain by which it is lowered from a derrick; the *setting* is done by divers. The wall extends into the river to various distances, — at Christopher Street 250 feet, — beyond the present front; the intermediate space will be filled in with rubbish and paved. The work, when completed, is designed to extend around nearly the whole circumference of Manhattan Island. At present (November, 1874) operations are in progress at the Battery, at the foot of Canal Street, and at the foot of Christopher Street; all on the North River side. See FLOATING-DERRICK; WHARF.

Sea-way Meas'ur-er. (*Nautical.*) A self-registering log invented by Smeaton. See LOG.

Se-bil'la. (*Masonry.*) A wooden bowl, to hold the sand and water used in sawing or grinding marble, etc.

Sec'ond-coat. (*Plastering.*) The second layer of plastering on lath.

It is called *set* in two-coat work, and *floating* in three-coat work.

Sec'ond-cut File. A file whose teeth have a grade of coarseness between the *bastard* and *smooth*. The grades are: —

Rough.	Second-cut.
Middle-cut.	Smooth.
Bastard.	Dead-smooth.

The angle of the chisel in cutting is about 7° from the perpendicular.

Sec'ond Fut'tock. (*Shipbuilding.*) A frame-timber scarfed on the end of the futtock-timbers. The *futtocks* are a series of lengths of timber, which unite to form the frame, beginning at the *floor-timbers* and terminating at the *top-timbers*.

Sec're-ta-ry. (*Printing.*) A font of type in imitation of an engrossing hand.

This is a Pica Secretary Type.

This is a Great Primer Secretary Type.

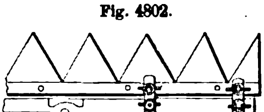
This is Italian Secretary.

Se-cret'ing. A process by which the *hairs* of hare and rabbit skins are rendered fit for felting. The skin is laid upon a table, and the hair side brushed with a solution of mercury, 32; aquafortis, 500; water, 300. The skins are then stoved, causing the retraction and curling of the hairs.

Sec'tion. (*Drafting.*) The geometrical projection on a plane surface of that portion of an object lying beyond an imaginary intersecting plane.

Sections are *longitudinal, transverse, vertical, horizontal, oblique, central, lateral*, etc., according to position and direction.

Fig. 4802.



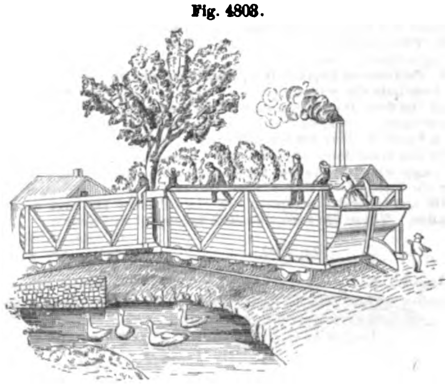
Harvester-Knife.

2. (*Surveying.*) A view showing the inequalities of the ground in reference to a base-line or line of construction.

3. (*Machinery.*) A detachable portion of a machine or instrument when made up of a number of parts: *e. g.* one of the triangular knives; a row which is attached to the cutter-bar of a harvesting-machine.

Sec'tion-al Boat. A boat made up of several independent sections, or, in fact, several boats, jointed together at their ends, so as to conform to sudden bends in the channel, or disconnected, so that each may be separately conveyed over a portage. Boats of this kind were constructed for river navigation in Russia by General Sir Samuel Bentham,

Fig. 4808.



Sectional Boat.

toward the close of the last century, and have been employed on the Morris and Essex Canal in New Jersey. See Fig. 2665, page 1176.

Sectional boats for canal or navigation subject to occasional interruption by bends or rapids are described in King's English patent, 1802. They are specifically intended for use on inclined planes, as substitute for locks where summit water is scarce.

Bond's boat is made in two portions, united by a joint near the mid-length; each has a bulkhead, so as to be separately buoyant; and one is somewhat smaller than the other, so as to pack in the larger for transportation when empty.

Ingalls, January 3, 1865. The boats are linked together consecutively by joints at their ends, which permit a certain amount of flexion.

Heath, November 15, 1864. The abutting ends of the two sections leave a recess between them. The end rails of each project and lap over the deck of the other. The sections are drawn together by a windlass and rope, one of which is made fast to a "dead-eye" arrangement on the other.

Sec'tion-al Dock. (*Hydraulic Engineering.*) The sectional dock is intended to lift a vessel above the surface of the water, in order that its bottom may be cleaned.

It consists of a series of caissons connected with a platform, which is introduced below the vessel, and, the water being pumped from these caissons by means of steam-engines, the vessel is raised by their flotation. The apparatus is towed to any place where it is necessary to apply it.

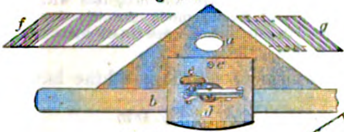
Sec'tion-al Steam-boil'er. (*Steam.*) One built up of portions secured together in such a way that the size may be increased by addition of sections; the working capacity being the sum of the whole, and the individual parts being separately removable for repair or substitution of new pieces. See STEAM-BOILER.

Sec'tion-beam. (*Warping, etc.*) A roller which receives the yarn from the spools, either for the dressing-machine or for the loom; in the latter case it is a *yarn-beam*. See WARPING.

Sec'tion-lin'er. A device for ruling parallel lines. It comprises a triangle *a*, which is held

against the side of a straight-edge *b* by a thumb-screw and a spring beneath the plate *d*, pressing against the under sides of both the ruler and triangle. The under side of the ruler is covered with rubber cloth, which, by its adhesion to the paper, prevents ready displacement, and the triangle is caused to advance equal intervals by depressing the button *e*, causing a pawl on the ruler to move the triangle a distance determined by the previous adjustment of the pawl. This adjustment is effected by means of a screw over the spring, which throws

Fig. 4804.



Section-Liner.

up the pawl after each depression, and permits parallel and equidistant lines to be ruled at various distances apart, at the will of the operator, as shown at *f g*.

Sec'tor. A mathematical instrument used for laying down plans, measuring angles, etc. It has two legs, united by a rule-joint, and graduated. The scales put upon *sectors* are divided into single and double: the former has a line with inches divided into eighths or tenths; a second, into decimals containing 100 parts; a third, into chords; the fourth has sines; the fifth, tangents; the sixth, rhombs; the seventh and eighth have latitudes, hours, etc.

Fig. 4805.

Sector.

The double scale contains a line of lines; a line of chords; third, a line of sines; fourth, tangents to 45°; fifth, secants; sixth, tangents above 45°; seventh, polygons.

In surveying, the instrument is mounted on a leg or tripod, and the bob depending from the axis of the rule-joint indicates the station exactly.

2. (*Astronomy.*) An instrument of long radius and small arc, as the DIP-SECTOR and ZENITH-SECTOR (which see).

Graham made the *sector* by which Bradley detected aberration and the instrument which the French Academicians carried to Lapland to measure an arc of the meridian.

3. (*Gearing.*) A toothed gear shaped like the sector of a circle, its face forming the arc. Its action is reciprocating, and the pitch of its teeth is not necessarily an aliquot part of the circumference.

Sec'tor-al Ba-rom'e-ter. Invented by Magellan. The hight of the mercurial column is found by the angle at which it is necessary to incline the tube, in order to bring the mercury to a certain mark on the instrument.

Sec'tor-cyl'in-der Steam-en'gine. (*Steam.*) An engine whose working-chamber is a sector of a cylinder, in which a rectangular piston oscillates to and fro like a door on its hinge. The axle of oscillation is a rocking-shaft to which the piston is fixed; and by means of an arm projecting from one of the outer ends of that shaft and a connecting-rod, motion is communicated to the crank.

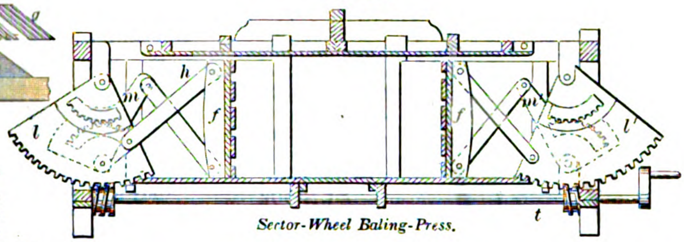
Sec'tor-gear. See SECTOR, 3; SECTOR-WHEEL.

Sec'tor-wheel. (*Gearing.*) *a.* A wheel, or rolling lever, which has the shape of a sector of a circle, a portion bounded by two radii and an arc.

It is used as a gear-wheel in machines when an impulse of moderate length is required, and has a reciprocating rotary motion.

In the illustration shown, — as an example of the use of a sector-wheel, — it is embodied in a form of baling-press, in which the followers *f f* are coincidently advanced or retracted, to press the bale or open for a new charge, as the case may be. The right and left hand screws of the shaft *t* operate cogged sectors *l l'*, whose oscillation actuates the toggles *h m m'* by which the followers are mutually approached to press the hay, etc., into the compass of a bale.

Fig 4806.



Sector-Wheel Baling-Press.

The motion derived from the worms on the shaft is imparted by means of three sector-gears, at each end, to toggles which move in unison, and are pivoted to different parts of the follower, so as to make it move squarely in the box.

b. A cog-wheel whose perimeter is formed of sectors of varying radii, imparting a variable motion to a wheel of counterpart form. A *variable wheel.*

Sec'troid. (*Architecture.*) A term applied to the surface of two adjacent groins in a vault.

Se-dan'; Se-dan'-chair. An upright conveyance for one person, much in vogue during the last century. It was usually carried by two men, by means of a pole on each side.

A similar contrivance, termed *sella*, was used by the Romans under the Empire; the poles (*asseres*) were removable.

The name is derived from Sedan, in France, where they were originally made. Their introduction into England dates back to 1581.

Sir Sanders Duncomb obtained a patent or monopoly of their manufacture for 14 years.

In the reign of James I. the Duke of Buckingham incurred great odium by using one, requiring "free Britons to perform the work of beasts."

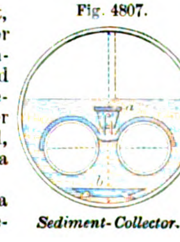
"Come in a sedan from the other end of the town." — PEPYS'S *Diary*, 1667.

The reigns of Queen Anne and the first Georges seem to have been the golden age of the sedan-chair.

Sed'i-ment-col-lect'or. (*Steam.*) A device to prevent the deposition of sediment on the bottom of boilers. An inverted hollow cone, whose mouth is a little above the water surface of the boiler. It communicates with the rest of the boiler by triangular openings near its upper edge. Scum and temporarily floating crystals of salt and solid matter passing into the comparatively still water of the cone, settle to the bottom, or apex of the cone, and are thence blown off.

Scott's (English) patent, 1827, consists of a vessel or series of vessels placed longitudinally of the boiler, and acting as a false bottom to receive the deposit. The water within these remains tranquil, while that outside may be in a state of violent ebullition.

Fig. 4807.



Sediment-Collector.

The upper collector *a* is a cast-iron trough suspended be-

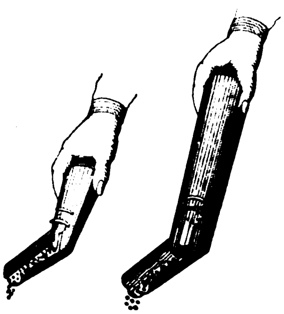
tween the flues, and partially or entirely covered with one or two cast-iron lids. This catches and retains the finer deposits which float near the surface.

The lower collector *b* is merely a shallow tray on four legs, slightly elevated above the bottom of the boiler, which receives the heavier particles deposited. See also INCRUSTATION IN BOILERS, PREVENTING.

Seed-drill. A machine for sowing seed in rows. See GRAIN-DRILL; SEEDING-MACHINE.

Seed'er. Fig. 4808 is a seed-sower for gardens. It has a gate to graduate the rate of discharge as the implement is drawn along in the little furrow made by pressure of the share, or previously by means of a hoe. See SEEDING-MACHINE; GRAIN-DRILL, etc.

Fig. 4808.

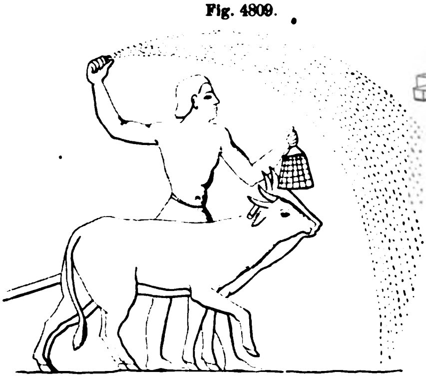


Seeder.

Seed'ing-ma-chine'. (*Husbandry.*) An implement for sowing seed. The term, in its general sense, may include machines for planting in hills, drills, or broadcast, but it is confined more usually to machines for distributing seed in drills or broadcast.

Seeding in Egypt was done upon the mud left by the retiring Nile. When Osiris retired within his banks, the fertilized ground brought forth, and the husbandman who scattered the seed from his basket

Fig. 4809.



Seeding in Egypt (from a Pyramid near Memphis).

was followed by the plows, the bush-harrow, or by a flock of sheep or goats, whose feet hid the seed beneath the surface of the soil.

There were three different modes of seeding grain in use among the Romans in the times of Varro and Columella.

1. The seed was thrown upon plowed ground and then plowed in.
2. The land was *ribbed*, or, as we say, *listed*, and the seed drilled by hand along the top of the ridge.
3. The land was *listed*, the seed sown broadcast, and covered by harrowing down the ridges.
4. The seed (such as vetches) was sown broadcast on unplowed land, and was then plowed in.

The Chinese have used a grain-drill for ages. At the present day their drill consists of a wheelbarrow carrying the seed-hopper, and having three hollow teeth, 28 inches in length, which draw a furrow into which the seed drops. This machine follows the plow, and is itself followed by the roller. See SEEDING-PLOW.

A native machine used in British India is substantially similar.

We find drills, both for seed and manure, mentioned by Worlidge in his "Husbandry," 1669.

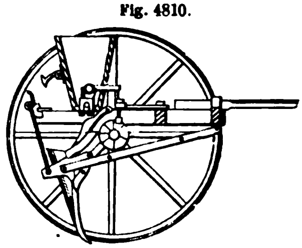
Evelyn, who was one of the founders of the Royal Society of England, and who died in 1706, wrote in high commendation of a *drill* which was the invention of Don Joseph de Lescatello, a nobleman of Carinthia, in 1663. This consisted of a seed-box, having a cylinder furnished with wheels to distribute the seed, and dropped the seed regularly in the furrow. It was fastened behind the stilts of the plow. The inventor was rewarded therefor by the Emperor Rudolphus II. He afterward took out a patent, in Spain!

It was recommended as saving 1/8 of the seed otherwise necessary on a given area. The Earl of Sandwich forwarded it from Spain to England.

In 1730, the invention came under the notice of Jethro Tull, the inventor of the horseshoe. He was delighted with the suitability of the instrument for his mode of cultivation, and its success was thenceforth established. See GRAIN-DRILL; CULTIVATOR; HOE; PLOW, etc.

Fig. 4810 is one form of seeding-machine having hollow shares drawn by drag-bars, and dropping into the furrow the seed which is uniformly fed from the hopper above.

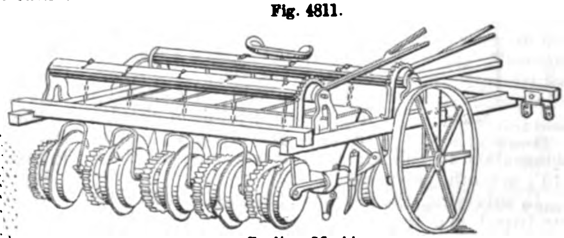
Fig. 4810.



Seed-Drill.

In Fig. 4811, the seed mechanism is actuated by the roller, which forms the earth into ridges, for protection of the seed. The relative vertical position of the parts is adjustable, to regulate the depth of planting. The rear rollers cover the seed. See also GRAIN-DRILL, Figs. 2278 - 81, pages 1002 - 4.

Fig. 4811.



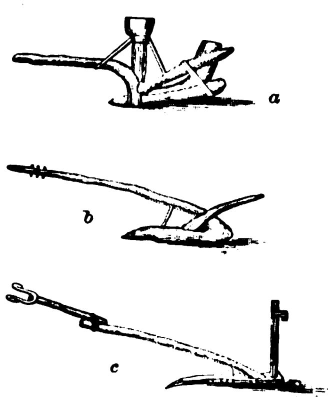
Seeding-Machine.

Howard's English grain-drill is driven by steam, sows a land 16 feet wide, and drills and harrows 20 acres per day.

Seed'ing-plow. A plow with a box, which drops or scatters seed in the furrow or on the fresh-turned earth.

a is an Assyrian plow from the "black stone" of Lord Aberdeen. The lithic record is of the time of Esarhaddon. It shows a grain-drill, with bowl for the seed, and a tube to lead it into the furrow.

Fig. 4812.



Oriental Plows.

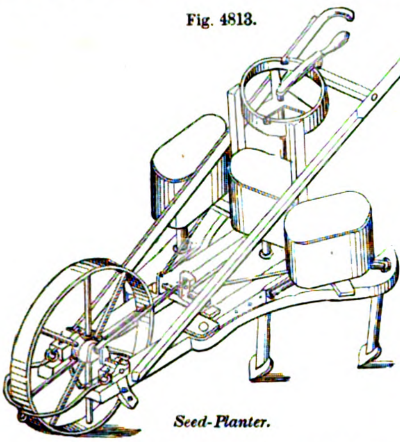
b is the modern Turkish plow.

c, the modern Arab plow.

Seed-plant'er. An implement for planting seed in hills.

Fig. 4813 is a hand implement, to be drawn by one horse. The seed-drill has a forward wheel, connecting by a crank and rod with the rod-shaft, which

Fig. 4813.



Seed-Planter.

communicates by rods with the seed-slides of the separate hoppers, which discharge into the seed-tubes of the shares. The side-bars are pivoted to the main frame, and are adjustable laterally by rack-bars and a central pinion.

Fig. 4814 is a machine for planting in check rows, so that the field may be cultivated both ways, in hills, instead of only one way, in drills.

The ground, having been marked out one way, is crossed by this machine, and as it reaches each intersection with the previous furrows, the lever is moved by the man who rides on the machine, and the seed is dropped. See Corn-planter, page 627.

Seed-sow'er. A machine for sowing grain, grass or clover seed, broadcast.

It is properly distinguishable from a grain-drill and a corn-planter, the former of which deposits the seeds and the latter the corn in hills. In *hill*, in *drill*, or *broadcast* are the three modes, and the latter is *sowing*. See Corn-planter; Grain-drill.

See'hand. (*Fabric.*) A fine muslin of a grade between nainsook and mull.

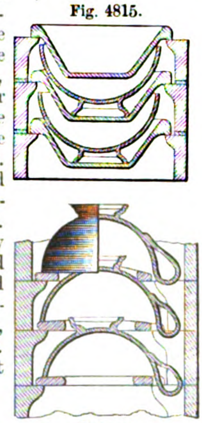
See'saw Pan. (*Sugar-manufacture.*) A rocking pan or boiler for evaporating saccharine juices. See Fig. 1890, page 813.

Seg'gar; Sag'gar. (*Pottery.*) An open box of clay, which receives articles of plastic clay or in the biscuit condition, and protects them while being baked in the kiln. The *seggars*, with their contents, are placed one above another in the kiln, the bottom of one forming the cover of the one below it. See Pottery-kiln.

The *seggars* vary in size and shape with the form and proportions of the contained ware.

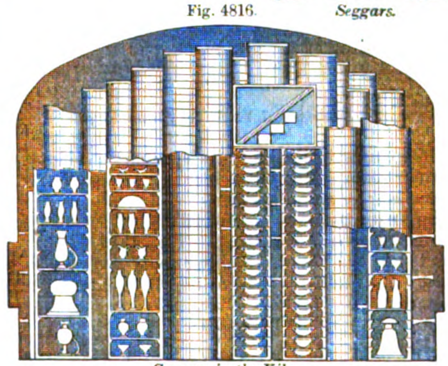
Seggars are made of fire-clay and old ground seggars molded into the shape required and baked. The articles are supported in the seggars by rings, ridges, or studs of fire-clay. In some cases the pieces rest one on another.

Fig. 4815.



Seggars.

Fig. 4816.



Seggars in the Kiln.

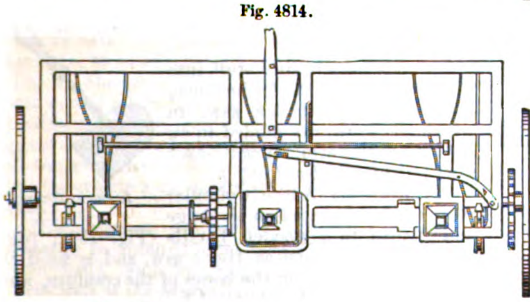
A kiln holds 30,000 average pieces inclosed in their seggars, a cylindrical pile of which is called a *bung*.

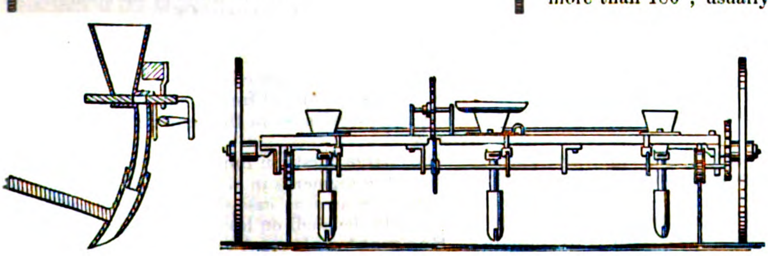
Fig. 4817 shows seggars for dishes and plates; they consist of a series of rings, and the plates rest on pins.

The term is one belonging to the potteries, and is variously spelt *seggar*, *saggar*, *segger*, *sagger*.

Seg-ment'al Arch. (*Architecture.*) One described from a center, and having less or more than 180°; usually less. The Washington aqueduct bridge, built by General Meigs, over Cabin John Creek, Maryland, consists of a single arch of this kind; it has a span of 220, a rise of 57 feet, and its span is exceeded by but one other stone arch in the world. See Stone Arch.

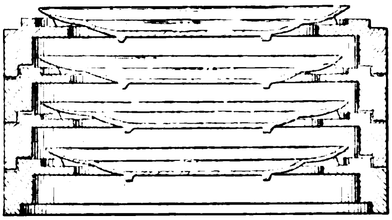
Fig. 4814.





Seed-Planter.

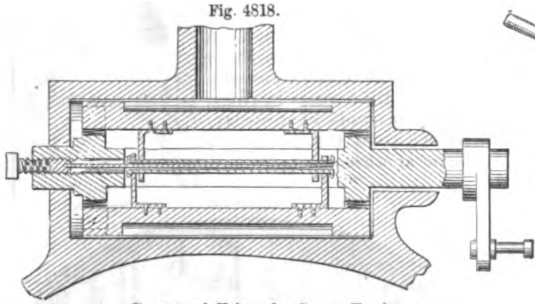
Fig. 4817.



Seggars.

Seg-ment'al Valve. A valve whose seating surface is a portion of a cylinder. In Fig. 4818, the segmental valves are connected by links which enter the slot of the stem. The links have rectangular holes traversed by tapering bars having a wedge between them which is swiveled in, and adjusted by a temper screw in the end of the stem to adapt them to their seats. The valve-blocks are also forced to their seats by spiral springs.

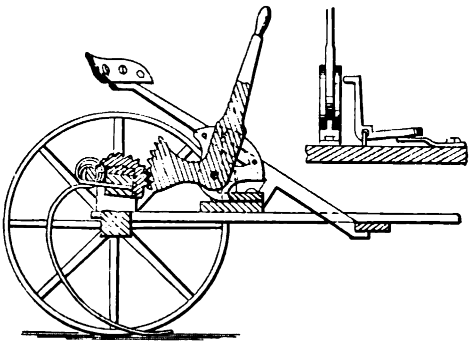
Fig. 4818.



Segmental Valves for Steam-Engine.

Seg'ment-gear. A curved cogged surface, occupying but an arc of a circle. Fig. 4819 shows it as applied to the hay-discharging apparatus of a sulky-rake. To discharge the rake, the operator presses his foot upon the stop and disengages it from the lever, which is then drawn backward by hand to raise the teeth.

Fig. 4819.

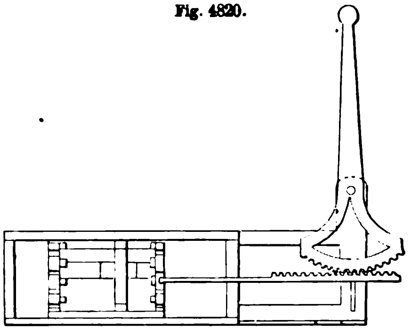


Segment Gear and Wheel.

Fig. 4820 shows a segment-rack applied to a rack on the staff of a dasher which reciprocates in a washing-box.

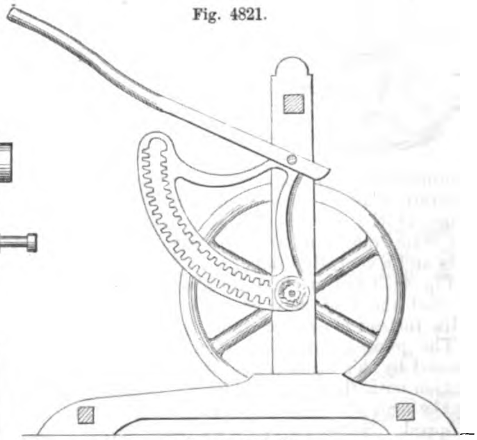
Seg'ment-rack. A cogged surface differing from the ordinary rack in being curved, so as to oscillate upon a center instead of reciprocating in slides or guides. In the example, the object is to convert the oscillating motion of one shaft into a continuous revolving motion of another shaft.

Fig. 4820.



Segment Gear and Rack.

Fig. 4821.

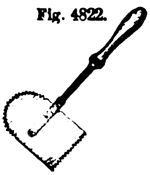


Segment-Rack.

Seg'ment-saw. 1. (*Wood-working.*) *a.* A *veneer-saw.* One whose active perimeter consists of a number of segments attached to a disk or hub. The invention of General Sir Samuel Bentham before 1800. See VENEER-SAW.

b. A saw which cuts stuff into segmental shapes; as, for instance, Sir Samuel Bentham's saw, in which the work was guided in an arc by a radius arm. A *chair-back* saw. It may be *band* or *jig.*

Fig. 4822.



Segment-Saw.

2. (*Surgical.*) A nearly circular plate of steel serrated on the edge and riveted to a wooden handle (Fig. 2502, page 1100). It is known as Hey's saw, and is used in surgical operations on the bones of the cranium, and the metacarpal and metatarsal bones.

Seg'ment-shell. (*Ordnance.*) An elongated projectile invented by Sir W. Armstrong.

The iron body is coated with lead, and contains a number of segments of iron in successive rings, leaving a hollow cylinder in the center for the bursting-charge.

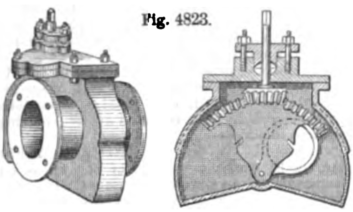
The charge bursts on impact or by a time-fuse, and scatters the segments in all directions.

It may be used as case-shot by arranging the fuse to explode the shell on leaving the muzzle.

Seg'ment-valve. A valve having a seating surface consisting of a portion of a cylinder. The valve

(Fig. 4823) for gas or water pipes is adjusted to the desired width of opening by means of a bevel-pinion

Fig. 4823.

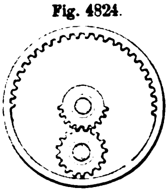


Segment-Valve.

working into a corresponding rack on the back of the valve. The case has a removable cover enabling the working parts to be taken out without disturbing the main pipe.

Seg'ment-wheel. A wheel a part of whose periphery is utilized. In the illustration, the wheel has two cogged segmental portions, which act alternately upon the pinion, giving a slow forward and quick reverse motion.

Fig. 4824.



Segment-Wheel.

Seg'ment-win'dow. (*Architecture.*) A window of segmental shape. A form of dormer or attic window, commoner aforetime than at present.

Seine. A large fishing-net.

Seine-boat. A fishing-boat from which the seine is cast.

Seis'mo-graph. An electro-magnetic apparatus for registering the shocks and undulatory motions of an earthquake.

Seis-mom'e-ter. An instrument for detecting earthquake shocks and recording their duration. The agitation or change of level of a mercurial column sets to work a delicate electric apparatus, which records the time of the first shock, the intervals between the shocks, and the duration of each; their nature, whether vertical or horizontal, the maximum intensity; and, in the case of horizontal shocks, the direction is also shown. The observatory established by the Italian government on the flank of Mount Vesuvius for watching the indications of threatened eruptions is provided with instruments of this class, which are sufficiently sensitive to be affected by any violent shocks occurring in the great Mediterranean basin. On the occasion of a late eruption in the Greek archipelago, Professor Palmieri was enabled to announce that a great disturbance had occurred long before the news of the event had reached Italy. Shocks occasioned by disturbances of Mount Etna are readily observable.

The eruptions are preceded by earthquakes, increasing in intensity and frequency for some days beforehand, and by irregularities in the diurnal variations of the magnetic needle.

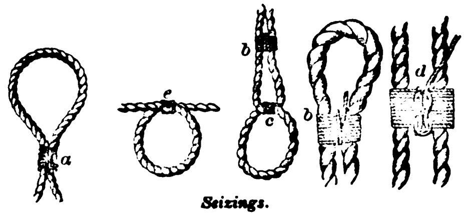
Seis'mo-scope. An instrument for recording the mensuration of the force and duration of earthquakes. A *seismometer*.

Seiz'ing. (*Nautical.*) *a.* The rope-yarn or stuff used for seizing.

a, eye seizing.
b, throat seizing.
c c, round seizing.
d, seizing secured with reef-knot.

b. Binding two ropes, or the two parts of the same rope, together, by means of smaller stuff.

Fig. 4825.



Seizings.

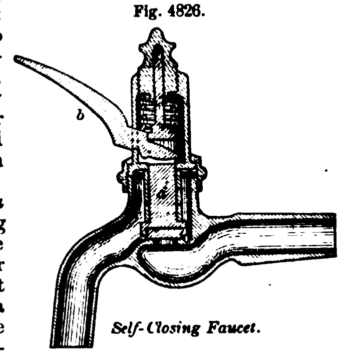
Self-act'ing Valve. One moved by the fluid, in contradistinction to one moved by the application of mechanical devices.

Self-clos'ing Bridge. A pivot bridge opened by canal-boats in passing. Made by Snyder Brothers, Williamsport, Pa. See patents: —

Schneider and Montgomery, September 4, 1860; Selfor, October 9, 1861; Winkler and Berndt, January 19, 1869; May 28, 1872; and October 8, 1872.

Self-clos'ing Fau'cet. A faucet having a valve which is held down to its seat by a spring to prevent the escape of liquid, and is raised by means of a lever when the liquid is to be drawn off.

Fig. 4826.



Self-Closing Faucet.

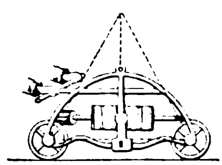
The valve *a* has an opening to receive the tail of the lever *b*, by which it is raised when a liquid is to be drawn; at other times it is held down by a spring.

Self-feed'ing Fur'nace. A magazine furnace in which fresh fuel from a hopper falls into the furnace as the coal is consumed.

Self-con-tained' En'gine. An engine and boiler attached together complete for working. Similar to the portable engine, but without traveling gear.

Self-re-cord'ing Lev'el. This machine is adapted for obtaining a *profile* or vertical section of a line of survey by passing over the track. A *grade-indicator.*

Fig. 4827.



Surveyor's Level.

The carriage traverses on wheels of known circumference, and one of these is geared to a drum, so as to rotate the latter at such a rate that a given length of the profile paper wrapped thereon will correspond to a certain distance traveled. The paper unwinds from one roller and wraps upon another, being subjected to the action of a pencil on the pendulum, which swings toward one end or the other of the drum as the carriage ascends or descends a hill, only maintaining a central position when traveling a dead-level. The drum can be shifted vertically to accord with any required scale.

Self-reg'is-ter-ing Ba-rom'e-ter. A barometer provided with devices for automatically registering variations of atmospheric pressure. See BAROMETROGRAPH; BAROGRAPH.

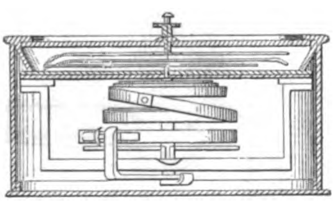
Self-reg'is-ter-ing Com'pass. An arrangement by which the compass prints a record of the

course in which the ship is steered. The compass carries on its under side a number of types, corresponding with the points of the compass. A strip of paper, moved by clock-work, passes under the card at that side which is next the bow of the vessel, and between the paper strip and the card itself is an inked type, which also travels slowly. At certain intervals the compass-card is tilted so as to bring the type which happens to be immediately above the paper strip at the time down upon the inked type, thus marking on the paper the course in which the vessel is being steered. The invention of Albini.

Another self-recording compass is that of Gordon, December 8, 1863, in which the course of a ship is recorded by dropping little pellets into boxes. It consists of a registering marine log and a compass divided into compartments for the reception of pellets, and an apparatus for dropping a pellet into one of said compartments whenever the vessel has made a certain distance, the delivering-tube or portion of the said dropping apparatus being so controlled as to always point in the direction in which the vessel is moving through the water. See MARINER'S COMPASS.

Self-reg'is-ter-ing Ther-mom'e-ter. One in which the indications of the instrument are recorded at regular intervals of time. The thermometer-needle is attached to a coiled metallic ribbon, whose expansion and contraction by change of temperature oscillate the needle. The independent needles are actuated by this one, and denote the extremes reached. These independent needles have thumb-burrs by which they may be turned. See THERMOMETER.

Fig. 4828.



Self-Registering Thermometer.

Sel'vage. 1. (*Locksmithing.*) The edge-plate of a lock through which the bolt shoots.

2. (*Nautical.*) A piece of very flexible rope, composed of yarns not twisted together, but laid parallel and bound with marline.

3. (*Fabric.*) The edge or list of cloth, woven so as to prevent raveling.

Sel'va-gee. (*Nautical.*) A rope or ring made by a number of spun yarns laid parallel and secured by lashings. It is sometimes used in place of rope, being less likely to slip, and is more elastic.

Sem'a-phore. An apparatus for conveying information by visible signs, such as oscillating arms or flags by daylight, and by the disposition of lanterns by night. The various combinations may serve to indicate the numbers corresponding to certain expressions in a tabulated code, or may be employed to represent the letters of the alphabet.

In the prophecy of Jeremiah (588 B. C.), chap. vi. verse 1, we find: —

"O ye children of Benjamin, gather yourselves to flee out of the midst of Jerusalem, and blow the trumpet in Tekoah, and set up a sign of fire in Beth-haccerem; for evil appeareth out of the north, and great destruction."

Homer, some 400 years before, had compared the aureola which surrounded the head of Achilles to the signals made in besieged cities, by fires at night and clouds of smoke by day; and Æschylus, more than a century after Jeremiah, using perhaps a poetical license, makes Agamemnon announce the fall of Troy to Clytemnestra by beacon-fires, whose rays, darting from the Asiatic shore to Lemnos, were repeated from Mount Athos, whence the grateful news was in like manner telegraphed to Argos. Fire-signals were prepared by Mardonius to notify his master, "the great king" Xerxes, then at Sardis, of the second taking of Athens.

At a later period, Polybius describes a semaphoric system improved by him, in which messages were transmitted by spelling out the words. The letters of the Greek alphabet were divided into five parts, which were inscribed on an equal number of boards affixed to upright posts between two walls. The number of the post and the number of the letter on each board was indicated by the successive exhibition of from one to five torches above the wall. The signal in each case, as in modern systems of semaphoric telegraphy, was repeated at the receiving-station, to guard against mistakes.

Æneas, who lived in the time of Aristotle, invented a method of telegraphing in which a number of the phrases most frequently occurring in war were written at various elevations upon an upright board on a float in a vessel of water. Each station was provided with one of these, and at a given signal the water was allowed to flow from the vessels at each station until the required message on the board was on a level with the top of the vessel at the transmitting station, when a second signal was made, and the flow of water stopped; as the apparatus at each was precisely similar, the same inscription would at this moment be exactly on a level with the top of the vessel at both stations.

Signaling by the waving of flags and lanterns is practiced on railroads, and has been embodied into a code capable of great variety of expression in the United States Signal Service.

The Chinese and the ancient Scythians were in the habit of communicating information by means of fires and smoke, and the same practice prevailed within comparatively recent times among the Scottish Highlanders and the inhabitants of the borders.

From existing indications, fire telegraphy must have been extensively employed by the ancient mound-building race which preceded the Indians who inhabited North America when it first became known to Europeans. Throughout the West, notably in the Scioto and Miami Valleys, mounds of earth thrown up in elevated positions are found which were evidently designed for this purpose. The permanent nature of the fortifications and the character of the entombed remains suggest that the region was at one time inhabited by a nation or nations more numerous and possessing a higher degree of political organization than their successors.

Fremont speaks of the signal-fires lighted by the Digger Indians and other aborigines inhabiting the margin of the great basin inclosed by the Rocky Mountains and the Sierra Nevada, to warn their neighbors of the progress of his party.

General Custer, in the "Galaxy" for July, 1874, thus describes the process: —

"First gathering an armful of dried grass and weeds, this was carried and placed upon the highest point of the peak, where, everything being in readiness, the match was applied close to the ground; but the blaze was no sooner well lighted and about to envelop the entire amount of grass collected, than Little Robe commenced smothering it with the unlighted portion. This accomplished, a slender column of gray smoke began to ascend perpendicularly. This, however, was not enough, as such a signal, or the appearance of such, might be created by white men, or it might take its rise from a simple camp-fire.

"Little Robe now took his scarlet blanket from his shoulders, and with a graceful wave threw it so as to cover the smouldering grass; when, assisted by Yellow Bear, he held the corners and sides so closely to the ground as to almost completely confine and cut off the column of smoke. Waiting but for a few moments, and until he saw the smoke beginning to escape from beneath, he suddenly threw the blanket aside, and a beautiful balloon-shaped column puffed upward like the white cloud of smoke which attends the discharge of a field-piece.

"Again casting the blanket on the grass, the column was interrupted as before, and again in due time released, so that a succession of elongated egg-shaped puffs of smoke kept ascending toward the sky in the most regular manner. This bead-like column of smoke, considering the hight from which it began to ascend, was visible from points on the level plain 50 miles distant."

During the Revolution, various methods were employed for signaling the movements of the enemy. Among others was a movable mast, having a barrel at top, a flag, and a cross arm from which a basket was suspended The various combinations to be effected by these means were capable of expressing a limited number of signals.

The Marquis of Worcester seems to have had in his mind an arrangement analogous to that of Polybius, the sight being aided by telescopes, then recently discovered. Such, at least, may be guessed of the very foggy description.

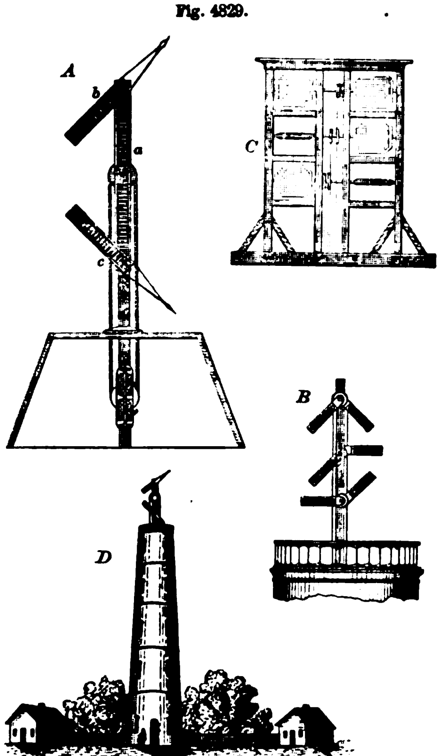
The learned and practical Dr. Hook followed in the same line, about twenty years afterward, and did not leave the matter in any uncertainty.

About 1700, Amontous exhibited a semaphore in operation, but the "Grand Monarque" was too busy with his Versailles and Marly to attend to it.

In the stirring times of the French Republic, when the National Convention was watching the Army of the North, Chappe constructed a semaphoric telegraph reaching from the Tuileries to Lisle.

As at present constructed, the Chappe telegraph (*A*, Fig. 4829) is composed of three pieces, — one large, called the regu-

Fig. 4829.



Semaphores.

lator, *a*, and two small, *b c*. The regulator is pivoted at its center, so that it may describe a vertical circle, and slides up and down a mast.

Its signaling positions are four: vertical, horizontal, right oblique, and left oblique, each of the latter forming an angle of 45°.

The indicators are pivoted to the ends of the regulator, and each may be placed in seven different positions, affording seven different signals in each position of the regulator; the various combinations which may thus be effected by changing the positions of the regulator and of the indicators are very numerous; in practice, however, no signal is made with the regulator in a vertical or horizontal position, so that the whole number is reduced to 196 simple and distinct signals, which, however, may be caused to succeed each other in such order as to form an indefinite number of combinations in accordance with a prearranged code.

Fig. 4830.

Semaphore.

The Prussian semaphore *B* consists of an upright mast having three wings on each side, pivoted in pairs one above the other, their combinations forming 4,096 signals.

In the English semaphore *C* an upright frame is divided into two compartments, each of which contains three octagonal panels turning on horizontal pivots.

Under the Emperor Nicholas I. a magnificent and expensive semaphoric system was introduced into Russia. The apparatus is placed on the summits of towers sufficiently high to overlook the tall pines with which the face of the country is covered, and placed at distances of five or six miles apart along the principal roads. This has succumbed to the less showy but more generally useful electric telegraph, and the lofty and conspicuous towers are now going to decay (*D*, Fig 4829).

Fig. 4830 shows a simple form of semaphore for railways. It consists of an upright post, whose top is adapted to receive a lantern, and having a pivoted arm which may be set in various positions by cords and levers below.

The basis of the signal system is simple. The three positions of the arm by day, and the three colors of a lamp by night, comprehend the alphabet and vocabulary of ordinary practice.

The arm horizontal, or a red light, intimates danger, and the necessary stoppage of the train.

The intermediate position of the arm, or a green light, enjoins caution, and a diminished speed.

The arm dependent or vertical, or a white light, implies that no obstruction exists, and that the train may proceed.

The value of carrier-pigeons was so plainly shown during the Franco-German war, that the French government has decided to erect a large house and to keep constantly in it for the next six years 5,000 pairs of pigeons for breeding purposes. Each fortress is to have a pigeon-house, with a capacity for 1,000 birds, and two general stations are to be established, with accommodations for 60,000 birds. The Germans, too, are breeding carrier-pigeons on a large scale for the use of the army.

Sem′i-cir′cle. A surveying instrument for taking angles. See DEMICIRCLE.

Sem′i-cir′cu-lar Arch. (*Architecture.*) One describing 180°. The versed sine is the radius of the describing circle.

Sem′i-grand Pi-a′no-for′te. A piano-forte having the shape and movement of a grand, but possessing only two strings to a note.

Sem′i-lor. A brass for cheap jewelry, etc. Copper, 5; zinc, 1. See ALLOY.

Sem′i-steel. A grade of steel. Puddled steel. Metal worked in the puddling-furnace, and the process terminated before all the carbon has been removed. See STEEL.

Sen′dal. (*Fabric.*) A thin kind of silk.

Sen′e-ca-oil. *Rock-oil.* The former name of petroleum or naphtha when it was collected from springs by the Seneca Indians and sold as a liniment. See PETROLEUM.

Sen′i-cal Quad′rant. An old form of quadrant consisting of several concentric quadrantic arcs, divided into eight equal parts by radii with parallel right lines crossing each other at right angles. It was made of brass or wood, with lines drawn from each side intersecting one another, and an index divided by sines also, with 90° on the limb, and two sights on the edge to take the altitude of the sun. It was in great use among French navigators. — ADMIRAL SMYTH.

Fig. 4831.

Sennit.

Sen′nit. 1. Braided cordage made by plaiting three or any odd number of ropes together (Fig. 4831).

2. A coarse hempen yarn.

3. Plaited straw or palm-leaf slips for hats, etc.

Sen′no-type. (*Photography.*) Another name for HELLENOTYPE (which see).

Sen′si-tive Pa′per. Paper prepared for photographic purposes. See next article. See also PHOTOGRAPHY.

Sen′si-tiz′ing. (*Photography.*) Applied to paper or to films.

The production on or in a surface or film of an insoluble salt of silver, generally chloride, iodide, or bromide of silver, which, under the actinic action of light, becomes colorably changed, or experiences such a change in its molecular constitution that, by a subsequent process of development, colorable changes are made to appear. In the former case, the image is at once *apparent*; in the latter, it is *latent* till the subsequent process has taken place. The process generally depends upon a double decomposition. For instance, paper charged with chloride of sodium being floated upon a solution of nitrate of silver, a film of chloride of silver, plus an excess of nitrate of silver, is formed upon the paper, the metal sodium uniting with nitric acid and passing into the bath. Or, in the case of the collodion film upon glass, the glass is floated with collodion containing bromides and iodides of the alkaline metals in solution, and the collodion "sets" upon the glass as a gelatinous film. It is then plunged into a bath of nitrate of silver, when a similar decomposition takes place, resulting in the production of insoluble bromides and iodides of silver, which become entangled in the film, while

the nitrates of the alkaline metals pass into the bath. The collodion film thus prepared is sensitive to light.

There are two exceptions where the double decomposition does not take place: —

1. In daguerreotyping. The production of a sensitive surface upon the plate by the action of the free vapors of iodine or bromine upon the surface of a clean metallic silver plate.

2. In the sensitizing of organic matter, such as gelatine, albumen, or gum, by the direct addition of salts of chromium, usually bichromate of potash.

Sen'si-tiz'ing-box. A dark chamber in which the operations described in the preceding article may be performed. See Hudson's patent, January 2, 1866.

Sep'a-rat'ing-sieve. A compound sieve used in powder-mills for sorting the grains according to their different sizes.

Sep'a-rat'ing-weir. A weir of masonry so contrived as to allow the waters to flow away during floods, but having an intercepting channel along the face of the weir to collect the water in medium stages.

Sep'a-ra'tor. 1. (*Husbandry.*) *a.* A machine for thrashing grain in the straw. See THRASHING-MACHINE.

b. A machine for clearing grain from foul, — dust, seeds, and chaff. See FANNING-MILL, page 825; WINNOWING-MACHINE; GRAIN-SCREEN, page 1007.

2. (*Metallurgy.*) *a.* A large pan set below the amalgamating pan in a mill. See SETTLER; SILVER-MILL.

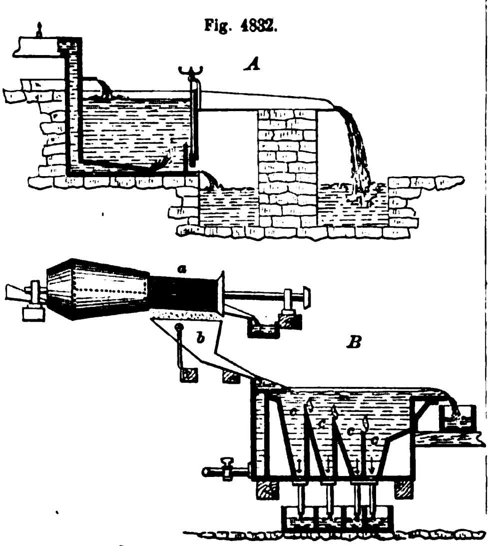
b. An ore-sorting apparatus in which an ascending current of water is directed against a descending shower of the comminuted ore, floating off the lighter and worthless portions, while the metalliferous matters sink to the bottom.

It will be observed that the resistance they experience while descending through water will be in proportion to the surface exposed; and, as the volumes of bodies vary according to the cubes of their relative dimensions, while the surfaces only vary as the squares of their measurements, it will be seen that the *force* of movement animating them is regulated by their *cubes*, while their *resistance* is in proportion to their *squares*.

In Wilkin's separator (*A*, Fig. 4832), the slimes and water are carried into a cistern from a trough above; a jet of water entering the bottom of the cistern carries the finer portions upward, where they are discharged, the heavier parts passing off through an opening below.

In another apparatus *B*, the slimes passing through a perforated trommel *a* are conveyed by a chute *b* into a cistern divided by partitions *c c c* into several compartments having apertures beneath. A pipe with a cock for regulating the flow of water enters the cistern at one end near the bottom, causing a longitudinal current therein; the particles, according to size, settling in the different compartments, pass out through the apertures in the bottom, the surplus water and finest portions being carried off at one end of the cistern. See also SIZING-CISTERN; LEAD-BATH, page 1269; CONCENTRATOR.

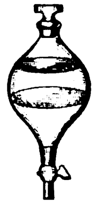
Fig. 4832.



Separators for Metallurgic Slimes.

3. (*Weaving.*) An instrument used by a weaver in spreading the yarn threads uniformly upon the beam of the loom. It resembles a comb, having teeth projecting from a head, and is of a length equal to the width of the web. The yarn threads pass between the teeth, and are maintained in the order in which they were disposed by the *warping-mill*. The instrument is also known as a *ravel*.

Fig. 4833.



Separator.

The *separator* or *ravel* is also used in spreading sized yarn upon the *balloon*; a large reel on which they are dried by rapid rotation in a steam-heated chamber.

4. A device for separating essential oils which are heavier than water from the water which comes over with them in the process of distillation. It consists of a bulbous glass vessel having a close-fitting stopper and an opening at bottom, provided with a stop-cock, by which the oil is drawn off, leaving the water remaining in the vessel.

5. A device or process for separating animal and vegetable fiber. The processes are usually destructive of one or the other. See, —

English patent, 2,621 of 1854. Animal matters dissolved by caustic alkali; or vegetable matters by acid.

105 of 1856. Sulphate of zinc, sulphuric acid; followed by washing in water, alkaline soap, etc.

970 of 1858. To destroy and separate the vegetable, sulphuric acid, and wash. To destroy the animal, potash or soda, sulphuric-acid solution. Rinse. Boil in chloride of lime and potash.

2,977 of 1859. Acid bath; press; wash; mechanical means. See Sykes, United States patent, No. 56,291, July 18, 1866. The wool is treated with diluted sulphuric acid, and the acid neutralized by lime-water, and the wool dried.

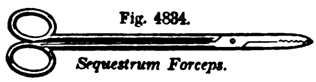
Sep'a-ra-to'ri-um. (*Surgical.*) An instrument for separating the pericranium from the skull.

Sep'a-ra-to-ry Fun'nel. A vessel of globular or spindle shape, having a narrow mouth, closed by a stopper, and terminating in a downwardly tapering pipe, frequently provided with a valve. It is often tubulated, and sometimes provided with two handles like a vase. It is used for separating chemical mixtures. See Fig. 4833.

Se'pi-a. A pigment prepared from the dark-brown secretion of the cuttle-fish.

Se'ques-trum For'ceps. (*Surgical.*) An instrument for removing portions of necrosed or exfoliated bone.

Fig. 4834.



Sequestrum Forceps.

Ser'aph-ine. (*Music.*) An enlarged form of the accordeon, introduced by Green. It was an organ with free-reeds, a key-board, and bellows worked by a pedal. It was the progenitor of the parlor organ, and has suffered a number of names, — *æolophon*; *physharmonica*; *æolomusicon*; *poikilorgue*; *harmonium*; *melodeon*; *symphonium*.

Serge. (*Fabric.*) *a.* A coarse-twilled woolen stuff, used for lining gig-saddles, etc.

b. A light silken stuff, twilled on both sides.

Ser-gette'. (*Fabric.*) A thin serge.

Ser'pent. 1. (*Music.*) A wooden wind-instrument covered with leather. It serves as bass to the horns and cornets, and has the same compass as the bass ophicleide, with rather more agility, pre-

cision in tone, and sonorousness. Its compass is three octaves and one note. It has three parts, — a mouthpiece, neck, and tail.

The *bassoon* is a low instrument of the serpent kind. It is written on the bass clef, and has a compass of from D below to A♭ above the clef.

Fig. 4835.

Serpentone (*from Bonanni*).

Fig. 4835 represents an instrument, Plate XXVI. of Bonanni's "Description des Instrumes Harmoniques," Rome, 1776. It is described as an instrument of very low tone, made use of in France and Germany as a bass to flutes and hautboys. It is hung from the neck of the performer, and would, if straight, be about six feet long. It has six holes for the fingers of the player.

2. (*Pyrotechny.*) A small paper tube filled with mealed powder or rocket composition, not very compactly driven. Serpents are used for filling paper shells or the pots of rockets, and pursue a wavering serpentine course through the air when ignited.

Ser′pen-tine. 1. (*Stone.*) A hard spotted or veined rock. It has many colors variously disposed. Greens and reds are prominent.

2. (*Ordnance.*) An old form of cannon of seven inches bore. The handles represented serpents.

Ser-pette′. A curved pruning-knife.

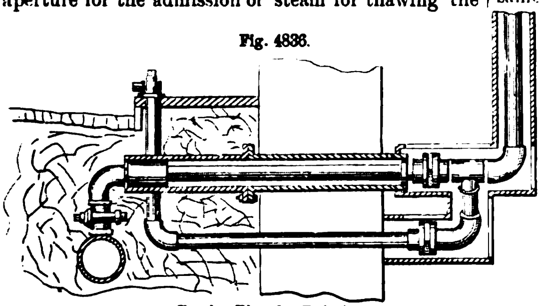
Serre-fine′. (*Surgical.*) A small clip used to compress a severed artery pending the farther conduct of the operation.

Serre-nœud. (*Surgical.*) An instrument used to tighten ligatures. See LIGATURE-TYER.

Ser′vice-pipe. One for conducting gas or water from the main into a building.

Fig. 4836 shows one arrangement. The pipe conveying water from the main is surrounded by a casing forming a chamber around the pipe. This casing extends to the inside of the building, and has an aperture for the admission of steam for thawing the

Fig. 4836.



Service-Pipe for Buildings.

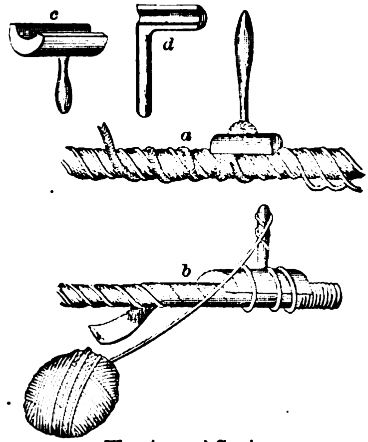
pipes. A wooden casing covers the pipes and their connections on the inside of the building, and has doors opposite the union and elbow joints.

Serv′ing. (*Nautical.*) Filling the interspaces between the strands of a rope by winding a smaller cord around it, as shown at *a*, Fig. 4837, is termed *worming*. The rope is then *parceled* by winding around it old canvas well tarred, the edges overlapping, to prevent water from penetrating, and is finally *served* by wrapping closely with spun yarn, to prevent chafing, as shown at *b*. In this process the *serving-mallet c*, or, for small jobs, the *serving-board d*, is employed.

Serv′ing-board. (*Nautical.*) A flat board used in serving ropes.

Serv′ing-mal′let. (*Nautical.*) A mallet-shaped tool used for wrapping spun yarn tightly around a rope. Several turns of the stuff are taken around the mallet, and as the mallet is rotated around the

Fig. 4837.



Worming and Serving.

rope which lies in the hollow, the stuff is tightly and closely wrapped around the rope. See *c*, Fig. 4837.

A *serving-board* is a flat piece of hard wood, with a handle, for similar duty on small ropes.

Set. 1. (*Machinery.*) *a.* A tool used to close plates around a rivet before upsetting the point of the latter to form the second head.

b. The lateral deflection of a saw-tooth, to enable it to free itself, by cutting a *kerf* wider than the blade.

This is done by a SAW-SET, which see.

c. An iron bar, bent into two right angles on the same side, used in dressing forged iron.

2. (*Locksmithing.*) A device for preventing the opening of a lock without its proper key.

3. (*Plastering.*) Or *setting-coat.* The last coat of plaster on walls for papering.

The last coat, for painting, is called *stucco.*

Set-fair indicates a particularly good troweled surface.

4. (*Metal-working.*) When metal is subjected to any strain, either tensile or compressive, the material is lengthened or shortened in proportion to the force exerted. When released from the strain it resumes its original length, unless the force exerted exceeded its limit of elasticity. If this occurs, the material receives what is called a *permanent set.*

5. (*Saddlery.*) The filling of deer's hair or other stuffing beneath the *ground seat* of a saddle, to bring the top seat to its shape.

6. An arrangement or combination of tools or machines acting in concert.

In the large saw-mills of Ottawa, Canada, at the Chaudiere Falls, a *set* consists of a *slabbing-gang* and *stock-gang* for the large logs; a *Yankee-gang* for the logs of 21 inches diameter and under; a *double-edger* for squaring the edges of the boards, and a *double-butter* for squaring the ends of the same. See SAW-MILL.

Set-bolt. (*Shipbuilding.*) *a.* One used as a *drift*, to force another bolt out of its hole.

b. A bolt used to bring a plank to its bearings. A *bringing-to* bolt.

Set-ham'mer. A hammer in which the handle is merely *set* in, not wedged; so as to be readily reversed.

Set-off. 1. (*Building.*) The part of a wall which forms a horizontal ledge when the portion above is reduced in thickness.

2. (*Printing.*) The accidental transferrence of ink from one recently printed sheet to another.

Se'ton-nee'dle. (*Surgical.*) A needle by which a number of threads of linen, silk, or cotton are introduced beneath the skin to keep up an irritation and discharge.

Set-pot. A copper pan, used in varnish-making. It is heated by a spiral flue which winds around it, and is used for boiling oil, gold size, Japan, and Brunswick black, etc.

Set-screw. (*Machinery.*) A screw employed to hold or move objects to their bearings. As the bits in a cutter-head, or brace.

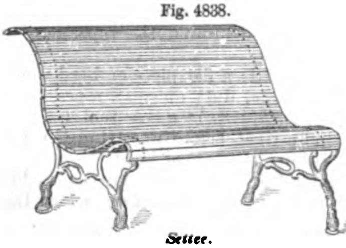
Sett. (*Piling.*) A piece forming a prolongation of the upper end of a pile when the latter has been driven beyond the immediate reach of the hammer.

Set-tee'. 1. (*Nautical.*) A Mediterranean vessel with a single deck, two masts, and lateen sails.

2. (*Household.*) A long-backed seat, for four or more persons. It is not upholstered; occasionally has rockers.

In Fig. 4838, the frame is of metal, to which longitudinal slats of wood with ventilating openings between are secured by rivets or bolts and nuts.

Fig. 4838.

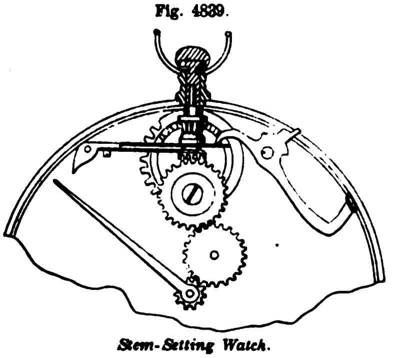


Settee.

Set-tee'-sail. (*Nautical.*) A sail intermediate in shape between a *lug-sail* and a *lateen*; that is, it has a weather leech of small hight.

Set'ter. (*Porcelain.*) A *seggar* adapted and shaped to receive an article of porcelain biscuit, for firing in the kiln. *Seggars* proper contain a pile of plates or other articles, but *setters* are specifically adapted for a single article of porcelain. Like *seggars*, they are made of a marly clay, and have lids, or each forms a lid for the one below it, when they are reared in *bungs* in the kiln. A *bung* is a pile of *seggars* or *setters* in place.

Fig. 4839.



Stem-Setting Watch.

Set'ting. 1. The sharpening of a razor on a hone. An intermediate process between *grinding* on a stone and *strapping*.

2. Displaying laterally the teeth of a saw in alternate directions, so as to increase the width of the kerf and allow the blade to move freely without rubbing and heating. See SAW-SET.

3. (*Masonry.*) *a.* Fixing stones in position in a wall.

b. The hardening of mortar, concrete, or plaster.

4. (*Plastering.*) A finishing coat of *fine-stuff*, laid on by a trowel; it is alternately wetted with a brush and smoothed with a tool until a fine surface is obtained.

5. (*Watchmaking.*) *a.* The jewel which is clasped by the bezel; or one which serves as a bushing for an arbor or pivot.

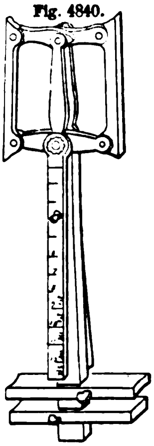
b. The adjustment of the hands.

Fig. 4839 shows Lange's plan for setting the hands by means of the stem.

Set'ting-coat. (*Plastering.*) The finishing coat of plastering which is laid upon the *floating* coat. The latter overlays the *rendering* coat. The setting-coat is of *fine* stuff, the others of coarse stuff.

Set'ting-gage. An apparatus for setting axles of wheels. By adjusting the graduated arms of the instrument in accordance with the dish and hight of the wheel, the pitch of the axle-arm may be readily determined; the object being to avoid the geometrical calculations usually involved. See also AXLE-SETTER, page 202; and AXLE-GAGE, page 201.

Fig. 4840.



Axle-Setter.

Set'ting-ma-chine'. (*Spinning.*) A machine for setting wire teeth in cards for carding-machines.

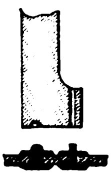
Set'ting-out Rod. (*Joinery.*) A rod used in setting out frames, as windows, doors, etc.

Set'ting-pole. (*Nautical.*) *a.* A pole by which a boat or raft is pushed along, one end resting on the bottom, and the other usually applied to the shoulder, while the man walks the length of the deck.

b. A pole driven into the bottom, and used for mooring a boat in fishing, etc.

Set'ting-punch. (*Saddlery.*) A punch with a tube for setting down the washer upon the stem of the rivet, and a hollow for riveting down the stem upon the washer.

Fig. 4841.



Setting-Punch.

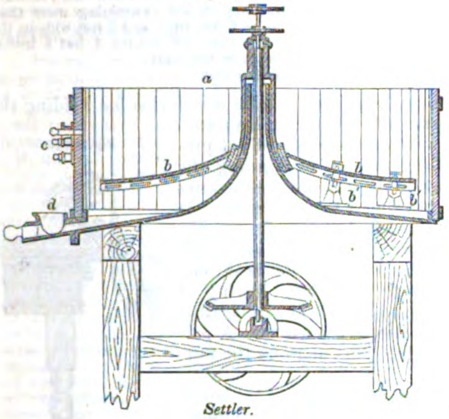
Set'ting-rule. (*Printing.*) A smooth piece of brass, the width of the *measure* of the column, and the hight of the type. It is used in the composing-stick, being withdrawn from beneath each completed line and laid above it to commence a fresh line.

Set'ting-up Ma-chine'. (*Coopering.*) A machine in which the staves of a cask are set up in order and held for hooping.

Set'tler. (*Metallurgy.*) An apparatus for extracting the amalgam from slimes received from the amalgamating-pan. It consists of a tub *a*, in which a series of sweeps or stirrers *b* provided with shoes *b' b'* are caused to rotate, imparting a centrifugal motion to the slimes, the lighter portions being drawn off through sluices *c* at various hights. These

are opened in turn from above downward, so as to draw off the lightest slimes first. The mercury and silver, sinking to the bottom, are received in an

Fig. 4842.



Settler.

annular trough, whence they pass into the cup *d*. The sweeps are adjustable as to hight by means of a screw. Also called a *separator*. See SILVER-MILL.

Set-up. 1. (*Metal-working.*) The steam-ram used in the squeezer which operates on the *loup* or ball of iron from the puddling-furnace. The action is to *up-set* or condense longitudinally the bloom, previously elongated by the action of the squeezer which ejects the cinder.

2. (*Bakery.*) One of the beech scantlings which form a frame around the congregated loaves in the oven and keep them in place.

Set-work. (*Plastering.*) Two-coat plastering on lath. *Laid and set.*

Sev'er-y. (*Architecture.*) A bay or compartment of a vaulted ceiling.

Sèvres Por'ce-lain. Porcelain of fine quality, made at the French government works, at Sèvres. It is principally of a peculiarly fine and delicate quality, for ornament rather than use.

Berlin, Dresden, and Munich have national ceramic works.

Sew'age. The surface drainage, slops, excrementitious matter, and other filth carried off by sewers.

Sewerage is a term applied to the sewers and drains of a town collectively.

When the sewers merely receive the street drainage and the liquid refuse from kitchens, etc., the disposition of this comparatively innocuous matter presents but little difficulty; it is discharged into the nearest running stream without danger of contamination.

Where, as is the case in densely populated cities and towns, water-closets empty into the sewers, the sewage not only tends to seriously contaminate the water into which it is discharged, but the foul gases generated therefrom, especially where the mouths of the sewers are wholly or partially closed at high water, are forced back into the houses, and prove very detrimental to health. This may, to some extent, be obviated by pipes leading from the soil-pipe to the highest part of the building, and open at top. This allows access of air to the drain, prevents the accumulation of gases, and facilitates their escape.

As the matters carried off by sewers contain a large proportion of fertilizing material, it has been proposed to collect and utilize them. The average value assigned by the English Rivers Pollution Commission is \$4 10 per 100 tons. The sewage of London is estimated at 260,000,000 tons yearly, worth over \$10,000,000.

To deodorize this and render it available for manure, various processes have been tried or suggested.

The lime process consists in mixing the sewage with milk of lime and agitating it. On settling, a putrescible mud subsides, and the comparatively clear liquid flows off. This process was not successful in England, the mud becoming very offensive in drying, and containing but a small proportion of valuable ingredients.

In Blyth's process, it was attempted to recover the ammonia from the sewage by the employment of superphosphate of lime and a salt of magnesia, to form an insoluble phosphate of magnesia and ammonia. The Sewage Commission considered this as ineffectual and costly.

In Holden's process, sulphate of iron, lime, and coal-dust are mixed with the sewage. The product is worthless as a manure.

In what is known as the *A B C* process, alum, blood, clay, and charcoal, mixed with water, are run into the sewage in a continuous stream. The results are said to be good.

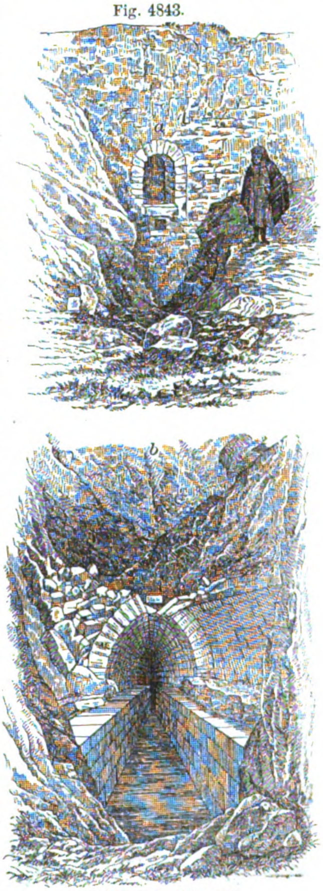
Dr. Morfit employs the mother water derived from the precipitation of pure phosphates of lime from hydrochloric solutions of mineral phosphates of lime, as practiced in his process for preparing fertilizers.

For deodorizing cesspool deposits, the dry-earth process is very efficacious; the earth, thoroughly dried and pulverized, is mixed with the contents of the cesspool, which may then be used at once as a fertilizer, or dried and kept until wanted, without giving out an offensive odor.

The cesspools of Paris, called *fosses d'aisances*, are usually, in interior dimensions, about 9 feet 10 inches × 5 feet 7 inches × 4 feet 11 inches, made of stone, and plastered inside, to prevent filtration, and provided with a manhole at the top, which is arched. They must undergo a municipal inspection before being used. The contents, when sufficiently fluid, are removed by pumping. More recently, removable air-tight tubs, termed *fosses mobiles*, which are placed in vaults made as nearly air-tight as possible, have been introduced into houses of the better class.

The contents of the cesspools are drawn off into air-tight wrought-iron vessels, termed *tinettes*, and conveyed by carts to two large elevated reservoirs at Montfaucon; these have an area of about $2\frac{1}{2}$ acres, and are apparently 12 feet deep; one being filled as the other is emptied. An overflow drain with sluice-gates at each end allows the liquid matter to run off into a basin at a lower level, where it deposits matters which may be held in mechanical suspension. On its banks are sal-ammoniac works, which are supplied from this source by pumping. The surplus liquid flows by a central sluice into two smaller reservoirs, where it is allowed to deposit its more easily precipitated matters, undisturbed by the pumps, the remainder flowing into four smaller basins, where the fertilizing materials still in solution are precipitated by straw, dead leaves, etc., and the water, now comparatively pure, is let off into the main sewer, which empties into the Seine, below Paris. In one plan the cesspools are emptied by exhausting the air from the carts which are made of boiler-plate iron; the liquid mass being forced into the cart through a pipe by atmospheric pressure.

Fig. 4843.



Sewers in Nineveh.

Sew'er. An underground channel for carrying off the surface water and liquid refuse matter of cities and towns.

Sewerage appears to have been carried to

a high degree of perfection at a very remote period of antiquity, those of Nineveh and Rome being among the best preserved remains of those ancient cities.

The most remarkable sewer of Rome was (and is) the Cloaca Maxima of Tarquinius Priscus, 588 B. C., formed to carry off the waters brought down from the adjacent hills to the Velabrum and Valley of the Forum. It had 3 concentric arches, the inner one a semicircle of 14 feet diameter, formed of hewn blocks, without cement. The whole sewer was 32 feet high, having a sectional area of 448 feet. (See Cresy's "Dictionary of Civil Engineering"; Smith's "Dictionary of Grecian and Roman Antiquities") Agrippa sailed through this sewer in a boat, and Nero caused some of his victims to be thrown into the sewers. So numerous were they that Pliny terms Rome *urbs pensilis*, a city supported on arches.

The arch has long been supposed to be of Roman origin; but this is abundantly disproved by remains in Egypt, Assyria, and Ethiopia. (See ARCH.) The Romans were the first to give it prominence in architecture, the Egyptians using it sparingly and hiding it, as it was not considered appropriate to their style: neither was it. The oldest arch in Europe is the Cloaca Maxima.

Fig. 4843 shows (*a*) an Assyrian arched drain of the Northwest palace Nimroud, and (*b*) one of the Southeast palace on the same old site. All the arches yet discovered are of brick, made of voussoir shape for the purpose. Some are sun-baked, and others kiln-burned. The greatest span found is 15 feet. They are usually semicircular. The only exception is that shown at *b*, in which ordinary bricks are used, the extrados being gained by wedges of mortar.

In no modern city, perhaps, is the system so complete as in Paris. Its origin dates back as far as the year 1412. The excavations made in order to obtain the limestone of which the city is largely built, and the catacombs, were subsequently made available for sewerage purposes, and now few streets are without these subterranean channels. The principal ones convey both foul and clean water, the former flowing along a trench at the bottom and the latter through pipes supported on brackets. They have one set of openings from the street to receive the drainage, another for the ingress and egress of the workmen, and a third for ventilation.

The *egout Rivoli*, under the street of that name, is probably the largest and most imposing. It has broad, neatly kept footpaths, and a railway along which visitors are conveyed in trucks pushed by men until its junction with the main sewer, when they are transferred to boats which convey them to the Place de la Madeleine, where a winding iron staircase leads to the street above.

Intermediate between this and the house drain are ten sizes of sewers, all except the two smallest having footways for the passage of the scavengers.

Telegraph lines, insulated with gutta-percha, and a pneumatic tube for the conveyance of parcels, are led through this sewer, and at intervals are vertical shafts provided with iron ladders through which the workmen can escape when it becomes flooded by rains. See SUBWAY.

The main sewer is cleaned by means of large barges having in front an iron plate which nearly fills the channel, and has three openings at its lower edge; as the barge is drawn up stream, the solid matter is forced through these and collected in a receptacle. Those that are too narrow for barges are cleaned by a similar device attached to a truck running upon rails on the footpath.

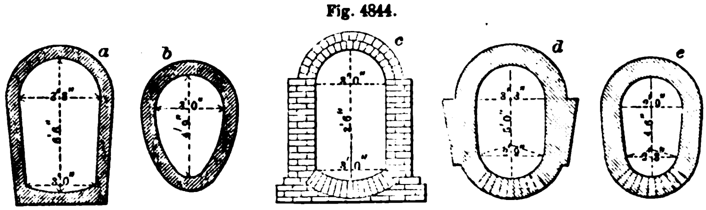
Up to the commencement of this century, the sewers of London were used exclusively for carrying off the surface-water and slops; cesspools, the contents of which were carried away in carts, being used for the reception of excrementitious matters. Subsequently these were diverted into the sewers, which discharge into the Thames. These were enlarged in 1855, but it was found that those receiving the drainage of the lower parts of the city were closed by high tides, forcing the filth and noxious gases back through the drains into the streets and houses. To remedy this, attempts at disinfection were made, but their want of success led to the adoption of a plan for intercepting the sewers by tunnels back from the river, and conveying their contents to a reservoir eight miles below the city, where they are deodorized, the liquid matter drawn off into the Thames, and the solid sold for agricultural purposes.

In Fig. 4844, *a* illustrates the shape and dimensions of a sewer employed in some of the London districts. In Paris, the form *b* is generally employed. *c* is used in the Westminster district, London. This form is not calculated to give the greatest strength, and in some instances the sides have been crushed in by the pressure.

An oval form *d e* is adopted by the Holborn and Finsbury Commission. Sewers draining streets containing more than 200 houses are required to be 5 feet high and 3 feet wide in the clear; those for streets of less than 200 houses, 4 feet 6 inches high, and 2 feet 6 inches wide in the clear.

London has 1,000 miles of sewers.

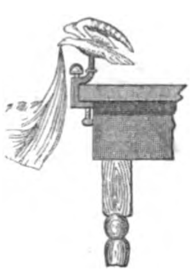
Fig. 4844.



Sewers (London and Paris Patterns).

Sew'ing-bird. This is a device for holding the work while sewing, and is a substitute for the old and yet prevailing custom of pinning the work to the dress above the knee in running a hem or seam. It has assumed many forms, the bird being ornamental and holding the work in its beak, one part of the bill having a spring to keep it closed against the stationary portion. A pair of spring jaws answers the purpose.

Fig. 4845.

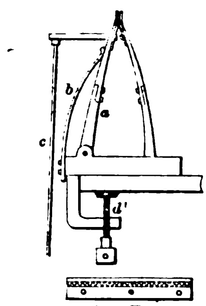


Sewing-Bird.

Sew'ing-box. A lady's work-box for sewing materials.

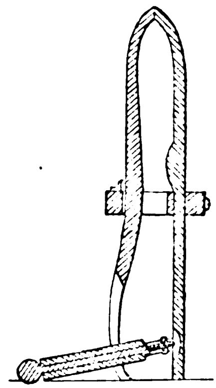
Sew'ing-clamp. (*Leather.*) A device for holding a piece of work while being stitched. In that illustrated, the movable jaw *a* is held to the leather by the spring *b*, and is thrown back by a rod or rope *c*, connected to a treadle. A screw *d* secures the clamp to a work-bench. The jaws may be serrated to take better hold of the work.

Fig. 4846.



Sewing-Clamp.

Fig. 4847.



Sewing-Horse.

Sew'ing-horse. (*Leather.*) A harness-maker's clamp for holding leather while being sewed. In the example, the clamping jaws of the horse are extended below the seat, and are provided with a treadle-lever, which is adjustable to suit varying thicknesses of articles to be sewn.

Sew'ing-ma-chine'. 1. Sewing-machines for fabric are of several classes: —

a. Those in which the needle is passed completely through the work, as in hand-sewing.

b. Those making the *chain-stitch*, which is wrought by the crochet-hook or by an eye-pointed needle and auxiliary hook.

c. Those making a fair stitch on one side, the up-

per thread being interwoven by another thread below.

d. Those making the *lock-stitch*, the same on both sides.

The last is the latest and best. See also *infra*, SEWING-MACHINE (for books), page 2119, and SHOE-SEWING MACHINE, Plate LIX.

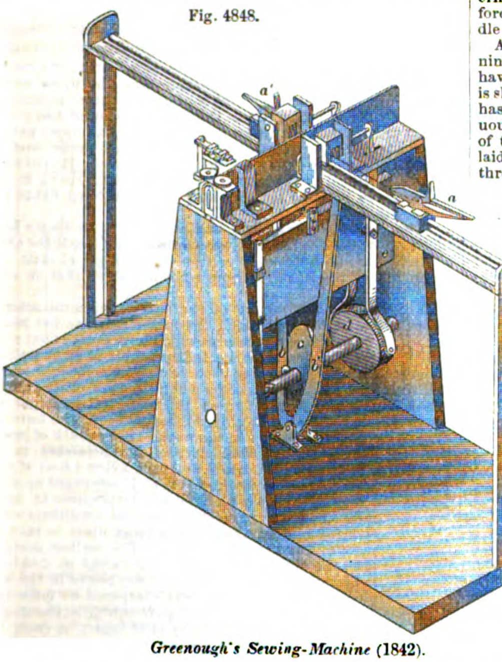
a. The stitch made by passing the needle completely through the goods, in the manner of hand-sewing, was the first performed by machinery. Such are classed as *short-thread machines*.

The needle with two points and an eye at midlength was patented in England in 1755. The embroidering-machine of Heilmann, patented (to Bock) in England, May 2, 1829, No. 5,788, for that purpose, was for a machine in which a large number of needles, each with an eye in the middle and a point at each end, or tambour-needles, are simultaneously actuated over a moving web of cloth, so as to repeat the patterns at various points from one "governing design" and on a more minute scale if desired. See also English patent, No. 6,931, of 1835.

Of Lye's sewing-machine, patented in the United States in 1826, no record exists. The fire of 1836 consumed all the records, and but few comparatively were restored, by means of recopying from the patents returned for that purpose.

J. J. Greenough's patent of February 21, 1842, had a similar needle, which was passed through and through the material by means of pinchers traveling on a track, and opened and closed automatically. The machine was specially designed for leather and other hard material, and the needle was preceded by an awl which pierced a hole. The material to be sewed was held between clamps provided with a rack, which was moved both ways, alternately, to produce a *back-stitch*, or continuously forward to make the shoemaker's stitch. The material was fed automatically at a determinate rate, according to the length of stitch required. The machine had a weight to draw out the thread, and a stop-motion to arrest the machinery when a thread broke or became too short. The needle was threaded with a length of thread, and required refilling. The feed was continuous to the length of the rack-bar, and then it had to be set back. The machine was not specifically useful, but possessed some valuable points. It holds a creditable place in the history.

Fig. 4848.



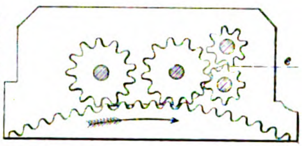
Greenough's Sewing-Machine (1842).

Fig. 4848 is a perspective view of the machine. One of the pincher-heads *a* is seen on the track, the other *a'* is nearly hidden by other portions of the machine. The levers *b b'* work the nipper-heads by means of cords, and are moved by cams *c c'* on the revolving shaft. A cam *d* on the shaft works the lever *e*, which reciprocates transversely and works the feed. The motions were all obtained from the revolution of a crank like the machine of Saint, 1790. That of Thimonnier, 1830, had a vertical needle worked by a treadle motion to depress the lever by a direct downward pull. Each of the machines mentioned was, however, much nearer to the type of the present machine than that of Greenough. The overhanging arm, vertically reciprocated needle, continuous thread, and automatic feed were patented in England fifty-two years before Greenough's, and sixty years before the Singer attained its excellence, as we shall have occasion to show presently.

The Corliss machine, patented in the United States December 27, 1843, No. 3,389, was of the same general mode of operation as the Greenough. It had eye-pointed needles reciprocated in horizontal paths through holes previously made by awls in the material fastened between clamps and fed in front of the needles. The feed was automatic, the length of the holding clamp. The motions were derived from peculiarly shaped cams on a revolving shaft. Many other details are worth enumerating would space permit.

An early form of sewing-machine, perhaps the earliest, was that employed for sewing lengths of calico together previous to the processes of bleaching, dyeing, and printing. The edges of the pieces being laid together and passed between fluted rollers, were thereby doubled or crimped and pressed on to the needle, which was held stationary in a horizontal position. See English patents No. 10,134 of 1844; also running stitch machine, No. 11,025 of 1846; No. 12,752 of 1849. The same feature is also seen in the United States patents, Smith and Chadbourne, April 16, 1850, and in No. 3,672, July 22, 1844, and shown in Fig. 4849. The cloth is crimped and forced on to the needle *e*.

Fig. 4849



Rodgers's Running-Stitch Machine.

Fig. 4850 is another form of the same kind of machine. The hand-crank works the feed-rollers and also the toothed rollers, which crimp the cloth and force it on to the needle *c*.

Another form of running-stitch machine having a curious analogy to the spiral needle for staphylorаphy is shown in Fig. 4851. This machine, patented November 3, 1874, has a spiral needle, shaped like a corkscrew, and with a continuous groove, in which the thread lies, being secured at the point of the needle by a spring. The edges to be sewed together are laid in the track of the needle, which is revolved, and passes through both edges once at each revolution. A bag is shown at *b*. See also Bean's patent, March 4, 1843, which used a common sewing-needle, and corrugated the cloth by means of gear-wheels, and forced it on to the needle.

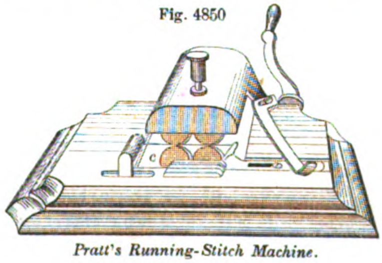
b. The *chain-stitch* or *tambour-stitch* is one consisting of a series, the bight of the thread being thrust through a former loop, and leaving a loop which in turn is enchained by the next-formed bight; and so on. There are several modes of making it, and while it was perhaps the first successful in a machine, it has been to a large extent superseded by other stitches. Several cheap forms of machines yet use it, and one kind, which has many friends, the "Willcox and Gibbs."

It may be made by a crochet needle and looping-hook, or by an eye-pointed needle and detaining-hook. It was the first machine-stitch in which the thread was continuous, the previous attempts having all been in imitation of hand-sewing, with a certain length of thread, threaded in the needle.

The first sewing-machine to make the chain-stitch is described in the English patent of Thomas Saint, July 17, 1790, which will be referred to presently. It is not known that working machines were ever made on this plan, but it cannot be ignored in a history which deals with records. Explicit notice is deferred for reasons explained farther on. Fig. 4854.

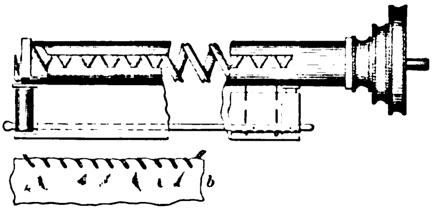
Next in order of date, making the chain-stitch, is Duncan's machine, English, No. 2,769, of 1804. It had a number of hooked needles, which passed through the

Fig. 4850



Pratt's Running-Stitch Machine.

Fig. 4851.



Garland's Spiral Needle for Sewing Bags.

cloth, then each was supplied with thread by a feeding-needle, which passed the thread around the crochet-needle and under the barb. As the needles receded, each drew a loop through the loop previously drawn by it through the cloth. The cloth was stretched between two cylinders placed parallel to each other in an oblong frame, which slid horizontally in another frame. Thus, either a horizontal or a vertical motion might be given to the cloth, or, by a combination of motions, an oblique direction. See also English patent, No. 10,102 of 1844.

Of the same class as the last two cited was the machine of Thimonnier, patented in France in 1830, and used for years in making army clothing. A fuller description of this machine is deferred so as to bring it into more immediate contact with the really valuable machines, of which it was, in many important respects, the forerunner. It had a thread-carrier beneath the goods, a crochet-needle which descended through the goods from above and caught up a loop which enchained the previous loop. Here we first see the presser-foot. This feature of a lower thread-carrier and hook needle is to be seen in the most valuable shoe-sewing machines of the present day.

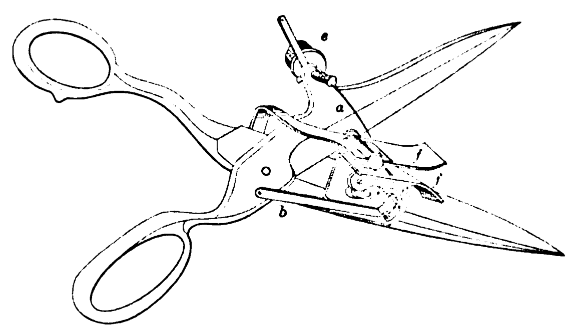
Sneath's machine was for producing *chain*-stitch ornaments on bobbinet in the process of making. It had a *curved needle with two eyes* for introducing a thread through the lace, and leaving a loop thereof; a pair of barbed points carried the loop over to the place where it was entered by the needle on its next stroke.

The eye-pointed needle is found in Newton and Archbold's English patent, No. 8,948 of 1841. This was some years after Walter Hunt's machine, and several years before Elias Howe applied himself to the task. We shall refer to this presently. In the English patent, No. 8,948, the eye-pointed needle carried a thread through the fabric and left a loop, which was caught by a hook and drawn lengthwise over the spot where the needle would pass through it on its next stroke. These features were afterward shown in the Johnson and Morey patent, February 6, 1849, and are yet extant in some machines of approved quality, though not of the highest class.

While considering this class of machines, it may be as well to adduce two rather amusing instances of the *chain*-stitch machines.

Fig. 4852 is a sewing-machine attached to a pair of scissors. The needle *a* is attached to the upper member of the scissors, as is also the bar *b* attached to the loop-check *c*, which is pivoted on the lower member of the scissors. *e* is the spool. The

Fig. 4852



Cutting and Sewing Machine.

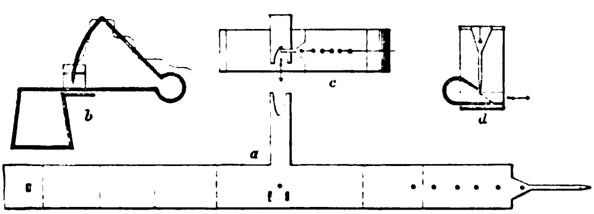
cloth passes between the plates *f f*, and the rate of sewing depends upon the length of the cut at each closing of the scissors, each stroke making a stitch. The eye-pointed needle carries the thread through the cloth, and leaves a loop on the hook; the next descent carries the thread through the former loop, making a chain-stitch.

Fig. 4853 is a sewing-machine made of a single slip of sheet-metal, and designed to make the chain-stitch.

a is the strip of metal, which is bent into the forms shown in the other figures, which are respectively, a side (*b*), top (*c*), and end (*d*) view. The thread is rove through the holes of the needle-holder and the eye of the needle, and, on being pressed through the cloth, pushes back the feeder. On rising, it leaves a loop on the under side, and, the feeder advancing, pushes the cloth along and the loop beneath it; the next time the needle comes down it passes through the former loop, and so on continuously.

c. The looping of one stitch by the loop of another is shown in Fisher and Gibbon's English patent, No. 10,424, of 1844. One thread is on a lower curved eye-pointed needle, which passes upward through the fabric, whereupon the upper eye-pointed needle enters between the former one and its thread; the curved needle, descending, leaves a loop upon the upper

Fig. 4853.



Sewing-Machine made of a Single Slip of Metal.

needle, the fabric being fed the length of a stitch; the curved needle again ascends, and, at the same time, the upper needle is moved in such a manner that it passes its thread around the curved needle and then retires through the loop of the needle thread previously upon its stem. After this, the upper needle, again advancing, enters between the curved needle and its thread, as before, and the movements are repeated. The enchaining of one thread by the loop of another thread is shown in several forms in Plate LVII. See also the Grover and Baker machine, Fig. 4863.

d. The last in order of date, and the best, is the simple lock-stitch, in which one thread is passed through a loop in the other one, and then both drawn so as to pull the bight of each into the middle of the fabric, making a fair line of stitches on each side.

In considering this section of the subject, we must refer to one or two inventions in which the lock-stitch was not made, but which possessed some features which have proved their right to live, and which seem to be indispensable in every well-ordered machine.

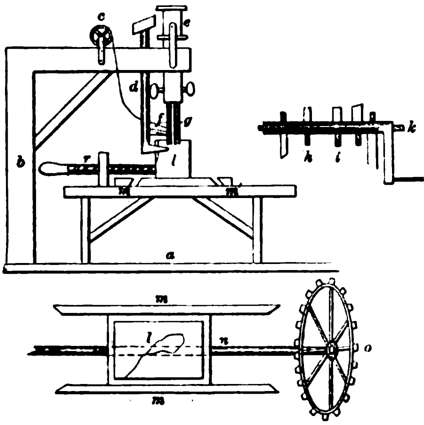
Ultimate success is attained by a multitude of efforts, and it is not fair, in our admiration of the perfected, to forget the weary, ill-appreciated, and unpaid efforts of those who have the earliest devoted themselves to the work. The growth of invention is in the direction of simplicity, but it is necessary, in the first place, to conceive the needs, and then follow a host of temporary expedients, — mere patchwork, as it afterward appears. In the course of time rises a reorganizer who proposes to devise means adequate to meet the changed conditions which supervene when a machine is called upon to take the place of the human operator. The earliest machine used the needle and needleful of thread in making a running-stitch. Then the eye was placed in the middle of the needle, which was sharpened at both ends to save turning it about when returning it, the needles being pushed and drawn by steel fingers on each side of the goods. The invention was as yet an implicit copying of the human manipulation, and the next change merely shifted the mode from the stitch of the *seamstress* to that of the *tambour-worker*. The needle was passed through the goods and returned, leaving a loop, which was detained, so as to be entered by the needle at its next descent, leaving another loop, and so on. A modification has been mentioned, consisting of a crochet-hook passed through the goods, bringing back with it a loop of thread from below, and enchaining it with the previous loop. This is all the small-beer of invention; the imitation of hands to use the familiar needle or the crochet-hook. There may be sedulous application and a certain merit in it, but there is no genius. The man of mark will find a new departure. He must devise new modes of procedure adapted to the needs of the new steel man, who is automatic but unskillful, and one of whose principal requirements is continuity of motion. If one must stop and thread his needle, he might as well return from the click and hum of the metal to the clatter of tongues which need no oiling.

The new elements were not invented all at once. One of the most important was overlooked for fifty years after it had been patented. Another was invented, made, and exhibited, and then slept a profound sleep of twelve years. Another was invented and patented, but was in a useless shape, and lay dormant until really valuable inventions were made, when it arose and claimed them as mere adaptations.

There is no important machine for sewing fabrics, now manufactured, that does not use all of the three elements mentioned, — the continuous thread, the eye-pointed needle, and the continuous feed, — but the former two of these had been in existence for sixty and twenty years respectively before they were united with the latter one, which, coming in the fruition of time, was more quickly recognized as a necessity.

Precedence in time is one of the governing elements in apportioning merit in invention. Some things may be perfectly invented, before assuming any concrete form in wood or metal. A man may be his own draftsman, or may call in his assistant to make the working drawings for a given kind of compound engine or a balanced valve. The workmen are the mere agents, and the engine or apparatus stands as the work of the designer. The ideas of a practiced engineer are concrete in the mind, as the attributes and accessories are all present in the conception of the thing; but with essayist and experimentalist the relations are different. With him the figure assumed in the mind is as yet untried, and unascertained conditions are yet to be provided for as they occur. With all allowance for the probable fact that no more than an experimental machine was actually made, yet the sewing-machine described in the English patent of Thomas Saint, No 1,764. and dated July 17, 1790, must still be regarded as a very remarkable link in the historical chain. It was intended for "quilting, stitching, and sewing, making shoes, and other articles by means of tools and machines." It possessed (1) a *horizontal cloth-plate;* (2) an *overhanging arm*, on the end of which was

Fig. 4854.



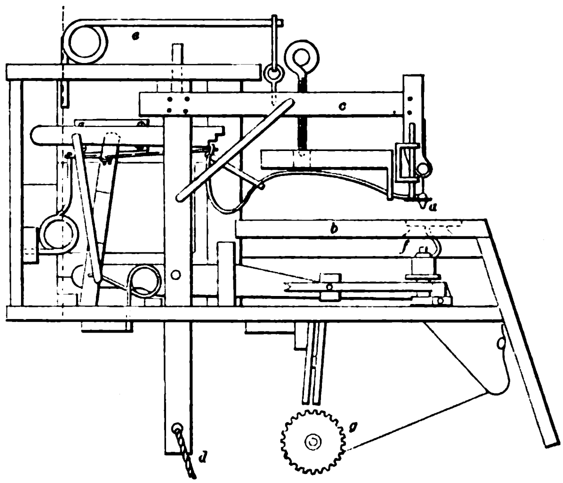
Saint's Sewing-Machine (1790).

(3) a *vertically reciprocating straight needle*, and on the top of which was (4) a *thread spool, giving out its thread continuously;* (5) an *intermittent automatic feed* between stitches; made the *chain-stitch;* and had thread tighteners above and below. This is marvelous. Its parallel is to be found in the sixteenth-century revolvers and repeating fire-arms in the European museums; weapons that were made before the voyage of Columbus.

The machine consisted of a bed-plate *a* with a post *b*, having a projecting arm on which was the thread-spool *c*; a shaft, rotated by a hand-crank and carrying cams by which all the motions of the machine were obtained; the same overhanging arm carried a spindle *d* for tightening the stitch, and a needle and awl-carrier *e*, into which a needle *f* and awl *g* were secured by set-screws, and moved by cams *h i* on the shaft *k*. The needle was notched at its lower end to push the thread through the hole made by the awl, and thus form a loop. The work was supported on a box *l* sliding between guides *m m* and advanced by a screw *n* turned by a toothed wheel *o*, which was engaged by a projection from an arm depending from the shaft *k*, at each revolution of the latter. A looper was operated by the bent point of the spindle *d* in a manner still employed in some of the chain-stitch machines. The screw *r* served to adjust the box *l* on the guide-plate, and provision was made for varying stitches for different kinds of work. The drawing has the peculiar features which should indicate that it was copied from a roughly made machine. The stiffening of certain parts of the frame was an incident of its making, and would not be necessary in a mere drawing. The overhanging arm would stand well enough, in a drawing, without the brace.

In 1830, Barthlemy Thimonnier patented a sewing-machine in France, which was so far successful that, in 1841, eighty of them, made of wood, were in use for sewing army clothing at a shop in Paris. They were destroyed by an ignorant and infuriated mob, just as the Jacquard loom and the Hargreaves spinning-jenny had been years before. Thimonnier escaped with his life, and again set to work. The Revolution of 1848 found him with another set of machines, capable of making 200 stitches per minute, and sewing and embroidering any material, from muslin to leather inclusive. Again the mob defeated his project and periled his person. He was in very straitened private circumstances, and the repeated destruction of the machines, built with money solicited from his friends, wearied at last even the admirers of his genius and energy.

Fig. 4855.



Thimonnier's Sewing-Machine (1830).

His machine was, like that of Saint, just described, in the form which subsequent experience has justified; that is, it had a vertical needle descending from the end of an overhanging arm *c* and piercing the goods, which was fed beneath upon a flat table *b*. The feed was by hand. Contrary to the machine of Saint, whose motions were derived from a crank, the needle in the Thimonnier machine was depressed by a treadle and cord *d*, and returned by a spring *e*. The Saint machine had a *forked* needle to push an *upper thread* through a hole previously made in the goods, when it was caught by a loop-check and detained, so that the again descending thread was enchained in the former loop, making a *chain-stitch*, consisting of a *series of loops on the under side*. The Thimonnier machine had a *crochet* or barbed needle which plunged through the goods and caught a *lower thread* from a thread-carrier and looper *f* beneath, and brought up a loop, which it laid upon the upper surface; descending again, it brought up another loop and enchained it with the one last made, making a *chain-stitch*, consisting of a *series of loops on the upper side*. Their points of similarity were those in which they resemble the best modern machines, — the flat cloth-plate, vertical post, and overhang-arm, the vertically reciprocated needle, and the continuous thread *g*. A nipple *a* sleeved upon the stem of the needle rested upon the goods during the descent of the needle, and was lifted when the needle was clear of the goods: the latter was then moved a distance equal to the length of a stitch, the needle and presser-foot (as the nipple *a* may be called) descended again, in its ascent carried another loop of thread through the loop previously made, and so on. Thimonnier died in poverty in 1857.

The Thimonnier machine, patented in France, August 5, 1848, and in the United States September 3, 1850. No. 7,622, had some advantages over his French machine of 1830, but retained its main features. The needle-bar was still worked by treadle and spring. See for his French patents Brevets D'Invention, Tom. V. page 168, and Plate XXVIII.; Tom XIV. page 71, and Plate XIV.

Between 1832 and 1834, Walter Hunt, of New York, made and sold sewing-machines which embraced a *curved eye-pointed needle* at the end of a vibrating arm, and a shuttle, making what is known as the *lock-stitch*. He neglected to pursue the business, which consequently attracted little attention at the time. His extreme versatility prevented success; his inventions absorbed his time, and he seemingly had none left for se-

curing the pecuniary results of his genius. He just missed, and by mere inattention, one of the grandest opportunities of the century. The main features of his machine had been patented, eight years previous to Hunt's application, to another inventor, — Elias Howe. When Hunt applied for a patent in 1854, it was refused him on the ground of abandonment.

The name of Elias Howe is indissolubly associated with the history of the sewing-machine. With inventive abilities inferior to those of Walter Hunt, he had an adaptedness to follow out a single object persistently, and he reaped the field. His patent was dated September 10, 1846, and was extended for seven years in 1860. In his petition to Congress, July 15, 1867, for a second extension of his patent, he acknowledged having received about $ 1,185,000, but considered that his invention was worth $ 150,000,000. If he had received the latter sum he would have been still more certain that it was worth $ 1,000,000,000, and so on.

The sewing-machine is no exception to the ordinary rule that an invention is a growth rather than an inspiration. The original machine, as we have seen, had a simple needle, and made a *running* stitch; next we see a machine which made a succession of loops, forming a *crochet* stitch; here the machine paused awhile. A score of years was passed in devising modes of feeding, continuous or intermitting, by various arrangements of parts. The greatest advance up to that time was the *lock-stitch*, invented by Hunt, and made by passing a shuttle containing a lower thread through the loop of an upper thread carried down through the cloth by an eye-pointed needle. This was also the feature of the Howe machine.

Howe was very properly declared the first inventor, technically, as the *laches* of Hunt had placed him outside of the protection of the law. This was framed (as determined by the decisions of the courts, which have so construed the law as to make distinct the point, which was, at best, indefinite) for the reward of inventors who make public their improvements. The legal point was with Howe, and bitterly Hunt rued his carelessness. He declared he would invent imitation stitched work more accurate than the original: the result was the paper collar with imitation stitching.

The original Howe machine had a curved eye-pointed needle attached to the end of a vibrating lever and carrying the upper thread. (See Fig. 4856.) The shuttle, carrying the lower thread between the needle and the upper thread, was driven in its race by means of two strikers carried on the ends of vibrating arms worked by two cams. The cloth was suspended by pins from the edge of a thin steel rib called a baster-plate, which had holes engaged by the teeth of a small intermittingly moving pinion. This was the feed, and clumsy enough. The invention soon fell into the hands of mechanicians of great ability, who timed the movements, proportioned and adjusted the parts, and added new features, without which the invention must have languished and failed of any remarkable success.

Elias Howe seems to have set himself to the problem in 1843; in 1844 he devised the curved needle and interlocking shuttle; in May, 1845, he had a machine at work. In 1846 it was patented. Thereafter the struggle in the United States and in England was to obtain funds for manufacture, and many weary, hungry days were passed by the indomitable inventor. He sold various shares of his invention from time to time, but when the tide turned in his favor he repurchased the rights, and soon made a compact property of it. It was not all smooth sailing even then, but the parties disposed to dispute his broad claims were induced to come under agreements of tribute or of neutrality. It was very well done. The original claims which concerned the eye-pointed needle and shuttle gave coherence to the confederate parties. The bond of union has since been the mode of feeding. A. B. Wilson's four-motion feed is so superior to all others, that but few first-class machines are made without it. This patent expired in 1873, and the dominant claim now is the Bachelder patent, which had no particular value in itself, but was, perhaps, really the first continuous feed, and so gained an utterly unexpected prominence and a lease of life for three terms, in all twenty-eight years, ending in 1877, although the device was but the substitution of a continuous spiked band for the plate of limited length. It is not true that Bachelder was the first to *horizontalize* the machine; that was done nearly sixty years previous. It had an endless band or cylinder studded with a row of points which carried the fabric to and past the needle. It was a decided improvement on Howe's baster-plate, which had to be run back for each length of sewing.

Without impugning the genius of the earlier inventors, it may fairly be said that the present proximate perfection of the machine is due to the men who took up the work where Howe left it, — to Singer, A. B. Wilson, and others.

Furthermore, the machine is much indebted to the skill and enterprise of the mechanics and tradesmen in whose hands it has grown to the wonderful proportions it now exhibits.

The Wilson shuttle, reciprocating in a curved race, was patented in 1850.

Lerow (1850), reciprocating eye-pointed needle and a shuttle traveling in an endless shuttle-race.

Robinson (1851) had two curved needles with notches or eyes and two thread-guides. Produced either the ordinary or the *back stitch*.

Singer's machine (1851) had a vertical needle-movement and a roughened feed-wheel extending through a slot in the table. A spring presser-foot alongside the needle held down the work. Motion was communicated to the needle-arm and the shuttle by gearing.

Grover and Baker (1851) used two needles and a shuttle carrying a filling-thread to form a double-loop stitch. The upper needle passed through the fabric and made a loop through which the lower needle passed horizontally, forming a second loop. See 13, Plate LVII.

The A. B. Wilson four-motion feed (1852) and the Wilson rotating hook (1851), which catches the loop of the upper thread and drops a bobbin through it, are features of the Wheeler and Wilson, — one of the most admired machines. As has been said, no substitute has been found for the four-motion feed. The shuttle has, however, more friends than the rotating hook.

Johnson's machine of 1853 made a double-loop stitch by two needles carrying continuous threads, and passing, by a horizontal thrust, through the cloth, which was suspended by clamps between them.

In Singer's chain-stitch machine (1854), the loop of the needle-thread was carried over a retaining pin by a hook and held until the next loop was formed, which was received by the looper and passed through the former one. Thus, a loop was passed through a loop, instead of, as in the tambour-stitch, passing the needle-thread and needle through the former loop. The feed in this machine was by the presser-foot, which had a rough under surface.

In Avery's machine (1854) (10, Plate LV.), the stitch is formed by interlooping threads from two needles, the lower one working at an angle of 45° with the upper one.

Noyes (1872), a lock-stitch with two commercial spools, the loop being made around the lower spool by a revolving hook.

Plates LV., LVI. show the principles of action of the sewing-machines. The numbers correspond with those on the Plates.

Description of Plates.

Single-Thread Chain-Stitch Machine.

1. The bearded needle pierces the cloth and draws up the loop from below; the cloth is then fed, the needle retaining the loop and descending through the cloth for a new loop, which enchains the thread.

2. The loop formed by the eye-pointed needle is seized and distended by a reciprocating loop-taker until penetrated by the needle at its second descent.

3. Similar to the above, excepting that the loop-taker vibrates.

4. The loop-taker *a* rotates. The Willcox and Gibbs pattern.

5. The looper is operated by the pressure of the needle, retreating before it and seizing the loop as the needle returns.

6. Needle-loop caught by a stationary hook that detains the loop as the cloth is fed, the next descent of the needle passing through the loop.

7. Latch-needle for enchaining or knitting the loop. See Stitch 6, Plate LVII.

Two Threads.

8. The loop of the needle-thread is caught by a thread carried by a reciprocating looper *a*. See Stitch 13, Plate LVII.

9. Similar to the above, but having a vibrating looper *a*.

10. Two needles penetrating fabric from opposite sides, and making Stitch 16, Plate LVII.

Lock-Stitch by Shuttles.

11. The loop of the needle-thread interlocked by the thread of the reciprocating shuttle *a*. Singer pattern, Stitch 19, Plate LVII. Florence, Howe, Wilson, Weed.

12. Similar as to the needle-thread; shuttle vibrates in an arc of a circle. "Domestic" pattern.

13. The loop of the needle-thread is taken by a rotating shuttle *a*.

14. The shuttle *a* is stationary, and the loop of the needle-thread is passed over it by a vibrating arm *b*.

Lock-Stitch by Revolving Hooks.

15. The rotating looper *a* enters the loop of the needle-thread and carries it around a loose disk-bobbin *b* on the face of the hook. Wheeler and Wilson pattern.

Leather-sewing Machine.

16. A waxed-thread machine. A hook-needle *a* below the cloth takes thread from a thread-carrier *b* above the cloth, draws down the thread, and enchains it below. An awl *c* perforates the leather for the passage of the needle; a cast-off *d* discharges the loop.

Sole-sewing Machines.

17. Machine for making "turned" shoes. The shoe and last are carried on a jack *a*. A chain-stitch is formed by a hooked needle, which passes through the sole and upper, and takes its thread from a thread-carrier. The awl *b* perforates the material for the passage of the needle. Dunham's patent, September 9, 1862.

18. The shoe is supported on a horn provided with a thread-carrier. A hooked needle penetrates the sole and upper, and takes the thread from the thread-carrier and forms the chain portion of the stitch in a channel cut in the outer face of the

CLASSIFICATION OF SEWING-MACHINES

Patented in the United States.

The figures in parentheses refer to corresponding figures on Plates LV., LVI.

CLASS A. MAKING CHAIN-STITCH.

1. *One thread*.....
   - *a.* Bearded needle (1).
   - *b.* Reciprocating loop-taker (2).
   - *c.* Vibrating loop-taker (3).
   - *d.* Rotating loop-taker (4).
   - *e.* Loop-taker operated by needle (5).
   - *f.* Stationary hooks or guides for holding loop in path of needle (6).
   - *g.* Latch-needle for enchaining loop (7). See also C, 1, 3, and 4; also E, 1; also F, 14 and 20.
2. *Two threads*....
   - *a.* Reciprocating under-thread carrier (8).
   - *b.* Vibrating under-thread carrier (9).
   - *c.* Rotary under-thread carrier.
   - *d.* Two needles, each penetrating fabric (10). See also E, 2.
   - *e.* Two or more kinds of stitches.

CLASS B. MAKING LOCK-STITCH.

1. *By shuttle*......
   - *a.* Shuttles reciprocate (11).
   - *b.* Shuttles vibrate (12).
   - *c.* Shuttles rotate (13).
   - *d.* Stationary shuttles (14).
   - *e.* Shuttle carries commercial spool.
2. *By revolving hooks*........
   - *a.* Wheeler & Wilson pattern (15).
   - *b.* Commercial spool for under-thread.
   - *c.* Hooks of various other patterns, making chain and lock stitch.

CLASS C. SEWING LEATHER.

1. *Machines* (16).
2. *Waxing devices.*
3. *Hose sewing.*
4. *Sole sewing*....
   - *a.* Curved needle (17).
   - *b.* Straight needle (18).

CLASS D. FEEDING.

1. *Needle.*
2. *Wheel or band.*
3. *Reciprocating surface above cloth*
4. *Reciprocating surface below cloth.*
5. *By movement of table.*
6. *By pressure against thread.*

CLASS E. BUTTON-HOLE.

1. *One thread* (19).
2. *Two threads* (20).
3. *Attachments for ordinary sewing-machines.*

CLASS F. MISCELLANEOUS PARTS.

1. *Bobbin-winders* (21).
2. *Cloth and slide plates.*
3. *Cutting and trimming fabrics on machine* (22).
4. *Lifting presser-foot.*
5. *Mounting machines on table.*
6. *Needles.*
7. *Needle-sharpener* (21).
8. *Needle setters and threaders* (23).
9. *Oil-can holder.*
10. *Oiling thread.*
11. *Presser-foot.*
12. *Quilting.*
13. *Regulating speed.*
14. *Running-stitch* (24).
15. *Sewing hats.*
16. *Sewing on buttons.*
17. *Sewing straw braid.*
18. *Sewing knitted goods.*
19. *Sewing umbrellas.*
20. *Short thread.*
21. *Shuttles.*
22. *Spools and bobbins.*
23. *Stitches.* See Plate LVII.
24. *Take-up.*
25. *Tension devices.*
26. *Thread-cutters.*
27. *Miscellaneous.*

CLASS G. ATTACHMENTS.

1. *Binders.*
2. *Braiders.*
3. *Corders.*
4. *Embroidering.*
5. *Guides.*
6. *Hemmers.*
7. *Rufflers and gatherers.*
   - *a.* Tension-plates.
   - *b.* Reciprocat'g blades
8. *Tuck creasers and markers.*
9. *Tuckers and plaiters.*
10. *Welt-guides.*
11. *Variety of work.*

CLASS H. TABLES AND STANDS.

1. *Tables.*
2. *Cases and cabinets.*
3. *Covers*
4. *Trays.*
5. *Lamp-brackets.*
6. *Work-holders*
7. *Aprons, guards*, etc.
8. *Chair.*
9. *Casters.*

CLASS I. MOTORS.

CLASSIFIED LIST OF SEWING-MACHINES AND ATTACHMENTS

Patented in the United States from Feb. 21, 1842, to March 9, 1875.

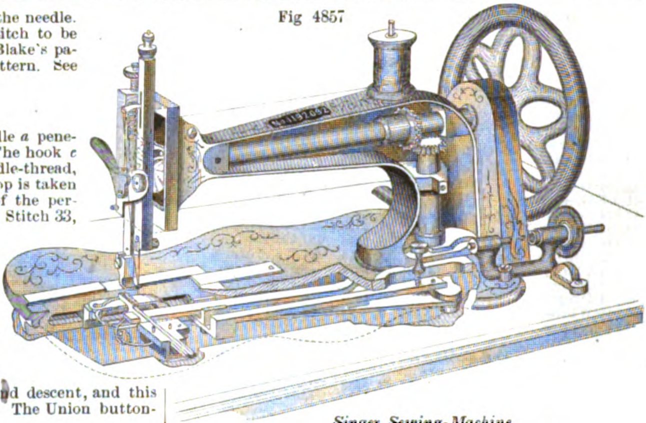
sole. A cast-off works in connection with the needle. The horn is so shaped as to allow the stitch to be formed near the shoe around the shoe. Blake's patent, July 6, 1858 McKay Association pattern. See SHOE-SEWING MACHINE, Plate LIX.

Fig 4857



Singer Sewing-Machine.

Button-hole Machines.

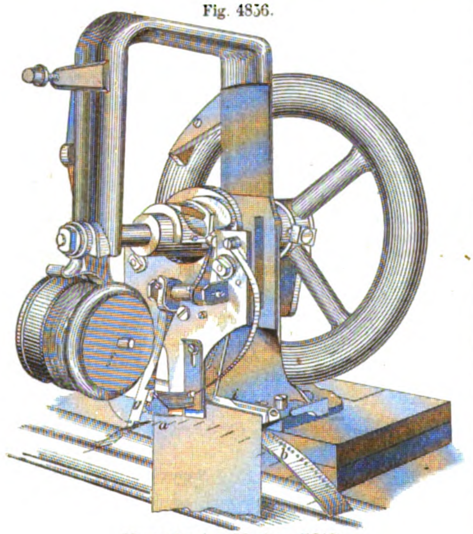
19. A single-thread machine. The needle *a* penetrates the fabric back from the edge. The hook *c* passes over the edge, takes the loop of needle-thread, draws it up over the edge, and then the loop is taken by the hook *b* and spread in the path of the perforating needle in its next descent. See Stitch 33, Plate LVII.

20. A two-thread machine. A hole is cut in the goods for the button-hole; the material is held in a clamp, which is moved under the needle, so that the latter makes a circuit of the button-hole a short distance from the edge. The needle descends alternately through the material back from the edge and then over the edge; the loop formed by the first descent is interlocked by the loop formed at the second descent, and this second loop is secured by a looper-thread. The Union button-hole machine of Boston.

Miscellaneous Parts.

21. A winder for shuttle-bobbins, which are held between the

Fig. 4856.



Howe Sewing-Machine (1846).

two heads and rotated by the contact of the friction wheel *a* with some rotating portion of the machine. *b* is an emery-wheel for sharpening needles.

22. A knife attached to the needle-bar to cut material parallel to the seam. In other instances a rotating cutter is attached to the cloth-plate.

23. A needle setter and threader. A device for placing the eye of the needle at the proper distance from the end of the needle-bar and for drawing the thread through the eye of the needle.

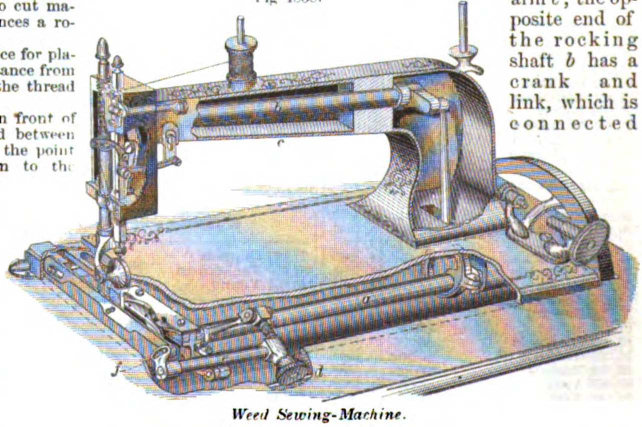
24. The material is raised and lowered in front of an ordinary sewing-needle, which is held between rollers that act to draw the material on to the point of the needle and off at the heel and on to the thread.

Fig. 4856 is the Howe sewing-machine, patented in 1846. It used a grooved and curved eye-pointed needle *a* carried by a vibrating arm *g*, the needle being supplied with thread from a spool *f*. The loops of needle-thread were locked by a thread carried by a shuttle *i*, moved through the loop by means of reciprocating drivers. The cloth was suspended in a vertical position, impaled on pins projecting from a baster-plate *b* moved intermittingly under the needle by means of a toothed wheel. The length of the seam depended upon the length of the baster-plate, and the seams were necessarily straight. On reaching the end of the length, the machine was stopped, the baster-plate returned to its original position, and the cloth again attached.

The Singer machine was patented in 1851 and subsequent years. The machine makes a lock-stitch by means of a straight eye-pointed needle and a longitudinally reciprocating shuttle. The needle-bar derives its motion from a pin on the end of the rotating horizontal shaft, the pin entering a heart-shaped groove in a block attached to the needle-bar. A bevel-wheel on the main shaft engages a bevel-wheel on the vertical shaft, provided at its lower end with a crank, connected by link with the shuttle driver or carrier. The four-motion feeding-dog is operated through the horizontal lever actuated from the vertical shaft. The feed is adjusted through a movable fulcrum, controlled by a set-screw. A take-up lever controls the thread between the tension device and the eye of the needle.

The Weed machine, as improved by G. A. Fairfield, and made under his patents, is shown in Fig. 4858. It makes a lock-stitch with a straight eye-pointed needle and reciprocating shuttle. The needle-bar is actuated from an eccentric on the main shaft *a*, which is connected by means of a link with a rocking shaft *b* in the goose-neck or overhanging arm *c*; the opposite end of the rocking shaft *b* has a crank and link, which is connected

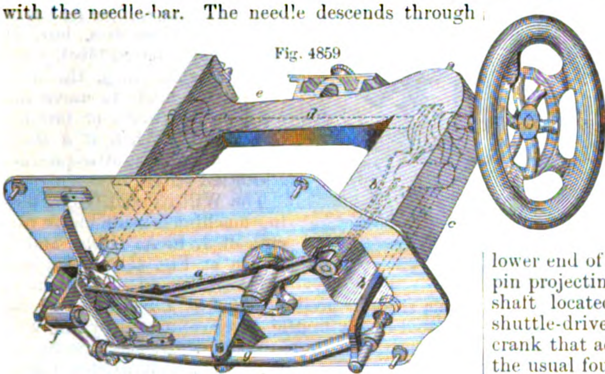
Fig 4858.



Weed Sewing-Machine.

with the needle-bar. The needle descends through

Fig. 4859



"*Domestic*" *Sewing-Machine.*

the cloth, rises sufficiently to form a loop to receive the point of the shuttle, then descends to slightly slacken the thread, and when the shuttle has passed completely through the loop, the needle rises to complete the stitch; a vibrating take-up, carried by the needle-bar and actuated through links, as shown, assists in tightening the stitch. A second eccentric on the main shaft is connected by means of a link with the shuttle-carrier, and another eccentric on the same shaft operates the feeding device.

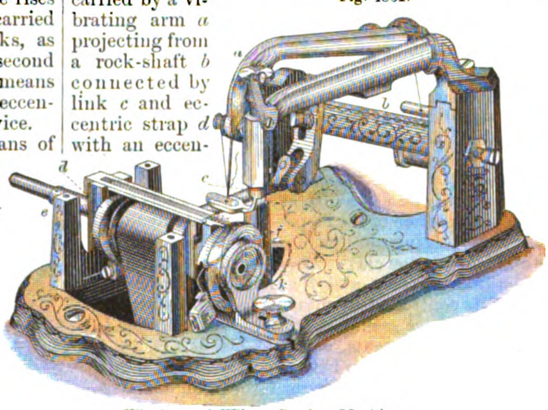
The length of the stitch is varied by means of the thumb-nut *d*, shaft *e*, and slotted cam *f*.

The "Domestic" sewing-machine, made under Mack's patents, is shown in Fig. 4859. It makes a lock-stitch with a reciprocating straight needle and a shuttle supported at the end of a horizontally vibrating shuttle-lever *a*, forked at one end to receive the ball-like end of a vertical lever *b* pivoted to the standard *c*, and forked at its upper end, so as to embrace a cam or eccentric on the main horizontal rotating shaft *d*, supported in bearings in the overhanging arm *e*, the shaft *d* having at its outer end a crank-pin to enter a curved slot in a block attached to the needle-bar, the pin and block reciprocating the needle-bar. The feed is of the four-motion class, deriving its motion from a bell-crank *f*, actuated by a horizontal lever *g*, moved by a vertically reciprocating connecting-rod *h*, driven by an eccentric on the main shaft *d*.

The Wilson sewing-machine (Fig. 4860) makes a stitch by a vertically reciprocating straight needle and a longitudinally reciprocating shuttle. The needle is moved by the action of a vibrating arm *a* pivoted to an upright *b* rising from the bed-plate. The lower end of the bent arm is slotted, and receives a pin projecting from a crank or disk on a short cross-shaft located directly under the upright *b*. The shuttle-driver is connected by link with the disk or crank that actuates the needle-arm. The feed is of the usual four-motion class, and the take-up *c* is a slotted arm actuated by means of a pin projecting from the needle-bar.

The Wheeler and Wilson sewing-machine (Fig. 4861) makes a lock-stitch by means of a curved eye-pointed needle carried by a vibrating arm *a* projecting from a rock-shaft *b* connected by link *c* and eccentric strap *d* with an eccen-

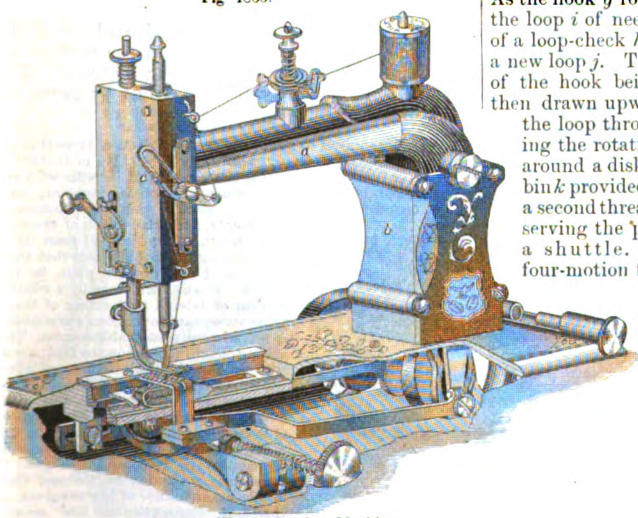
Fig. 4861.



Wheeler and Wilson Sewing-Machine.

tric on the rotating hook-shaft *e*, this shaft having at its outer end the hook *f*, provided with a point *g* (see Fig. 4862) adapted to enter the loop of needle-thread. As the hook *g* rotates, it passes into and draws down the loop *i* of needle-thread, which is held by means of a loop-check *h*, while the point of the hook enters a new loop *j*. Then the old loop *i* is cast off, the face of the hook being beveled for that purpose, and is then drawn upward by the action of the hook upon the loop through which it is then passing. During the rotation of the hook each loop is passed around a disk-bobbin *k* provided with a second thread and serving the part of a shuttle. The four-motion feed is

Fig 4860.



Wilson Sewing-Machine.

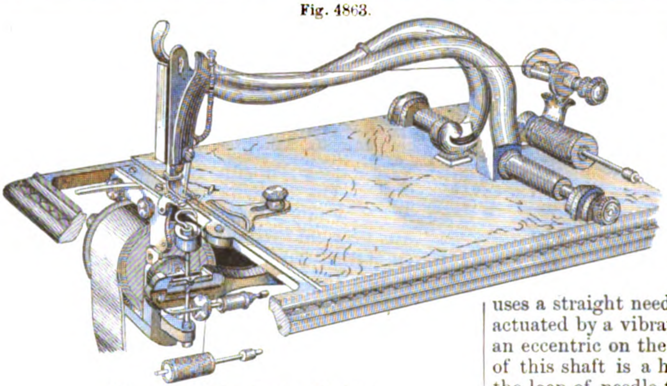
Wheeler and Wilson Hook.

Fig. 4863.



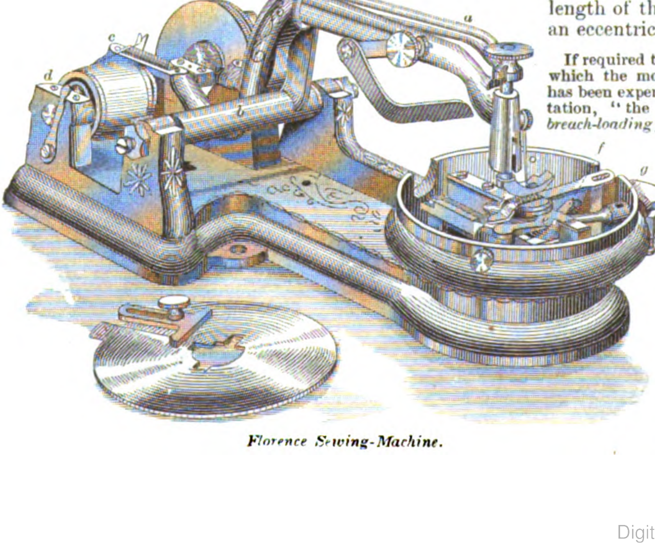
Grover and Baker Sewing-Machine.

the invention of A. B. Wilson, and is actuated in this machine by means of cams on the hook-shaft *e*. See also TAILORING-MACHINE.

The Grover and Baker machine (shown at Fig. 4863) makes the double-loop stitch (see Plate LVII.). It uses a curved eye-pointed needle and a rotary reciprocating curved thread-carrying looper *g*. The needle is carried at the upper end of a ⊃-shaped arm, slotted at its lower forward end, to receive an actuating pin upon a disk connected with the main shaft. The vertical looper-shaft has a spiral portion embraced by a slotted plate at the end of the ⊃-shaped arm, and as the latter vibrates it acts upon the spiral portion of the looper-shaft, and imparts to it a reciprocating rotary motion. The feed is of the usual four-motion class. The threads are contained on ordinary spools, and the slack of the needle-thread is controlled by means of a spiral spring.

The Florence sewing-machine is made under L. W. Langdon's patents, and is shown at Fig. 4864. It makes a lock-stitch by means of a curved needle carried by a vibrating arm or lever *a*, on a shaft *b*, which has a backward extension-yoke *c*, embracing an eccentric on the main shaft *d*. The shuttle-driver is actuated by the shaft *d* by means of a link. The needle and shuttle have constant motion, not having periods of rest, as in other machines. The slack of the shuttle-thread during the backward movement of the shuttle is taken up by means of a vibrating arm *e*. The feed is of the four-motion class, but, by means of a grooved block *f* and an adjustable pin *g*, the feed-bar may be made to move forward or backward, or brought to a stand. When at a stand the needle and shuttle produce a knotted stitch.

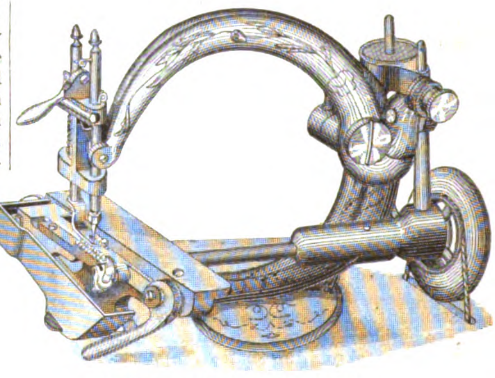
Fig. 4864.



Florence Sewing-Machine.

The Willcox and Gibbs sewing-machine is made under patents of J. E. A. Gibbs, and is shown at Fig. 4865. The machine makes a chain-stitch; uses a straight needle carried by a reciprocating bar actuated by a vibrating lever connected by link with an eccentric on the main shaft. At the forward end of this shaft is a hook, which, as it rotates, carries the loop of needle-thread, distends and holds it expanded while the feed moves the cloth, and until the needle at the next stroke descends through the loop so held. When the needle descends through the first loop, the point of the hook is again in position to catch the second loop, at which time the first loop is cast off and the second loop is drawn through it, the first loop being drawn up against the lower edge of the cloth, forming a chain.

Fig. 4865.



Willcox and Gibbs Sewing-Machine.

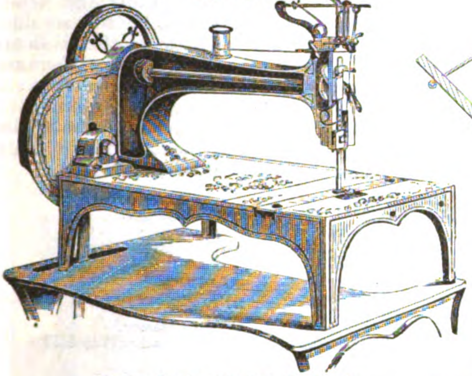
An eccentric on the main shaft, back of the rotating hook, enters a slot in the feeding-bar and gives it the usual four motions. The length of the stitch is governed by means of an eccentric lever.

If required to name the three subjects of invention on which the most extraordinary versatility of invention has been expended, the answer should be without hesitation, "the *sewing-machine*, *reaping-machine*, and *breach-loading fire-arm*." Each of these has thousands of patents, and, while each of them is the growth of the last 40 years, it is only during the last 25 years that they have filled any notable place in the world. It was then only by a combination of talents that either of these three important inventions was enabled to achieve any remarkable success. The sewing-machine previous to 1851, made without the admirable division of labor which is a feature in all well-conducted factories, was hard to make, and comparatively hard to run. The system of *assembling* — first introduced in the artillery service of France by General Gribeauval in 1765, and brought to proximate perfection by Colonel Colt in the manufacture of his revolver at Hartford, Connecticut — has economized material and time, and improved

the quality as well as cheapened the product. There is to-day, and in fact has been for some years, more actual invention in the special machines for making sewing-machines than in the machines themselves. The effect of this will be, when the adventitious aids of exclusive patents shall terminate, to give the larger and better equipped concerns a great advantage over smaller competitors.

What is true of one of the classes of invention named is true of the others, as well as of some not mentioned, — the American watch, for instance. The *assembling* system — that is, making the component parts of an article in distinct pieces to pattern, so as to be interchangeable, and then putting them together — is the only system of order. How else should the Providence Tool Company execute their order for 600,000 rifles for the

Fig. 4866.



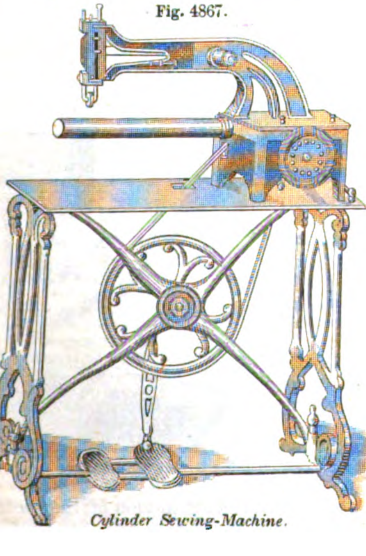
Singer Sewing-Machine for Leather.

Turkish government? How otherwise could the "Champion" Harvesting-Machine Companies of Springfield, Ohio, turn out an equipped machine every four minutes each working day of ten hours? Or, to draw the illustration from the subject in hand, how by any other than the nicest arrangement of detail can the Singer Sewing-Machine Company make 6,000 machines per week in their works at Elizabethport, New Jersey?

The data for showing the rate of increase of the sales of sewing-machines since the year 1851, is not accessible to the writer, even if it be obtainable at all. The sales have, however, largely exceeded half a million a year for four years past, and the following table is given as showing the sales of fifteen companies for the year 1874, but two of the numbers being estimated: —

	Machines.
The Singer Manufacturing Co.	241,679
Wheeler and Wilson Manufacturing Co.	92,827
Howe Sewing-Machine Co. (estimated)	35,000
Domestic Sewing-Machine Co.	22,700
Weed Sewing-Machine Co.	20,495
Grover and Baker Sewing-Machine Co. (estimated)	20,000
Remington Empire Sewing-Machine Co.	17,608
Wilson Sewing-Machine Co.	17,525
Gold Medal Sewing-Machine Co.	15,214
Willcox and Gibbs Sewing-Machine Co.	13,710
American Buttonhole Sewing-Machine Co.	13,529
Victor Sewing-Machine Co.	6,292
Florence Sewing-Machine Co.	5,517
Secor Sewing-Machine Co.	4,541
J. E Braunsdorf & Co., "Ætna"	1,866

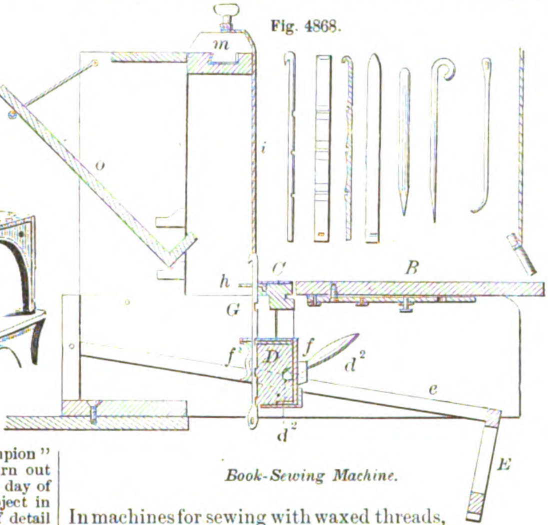
Fig. 4867.



Cylinder Sewing-Machine.

2. The sewing-machine for leather is similar to the ordinary straight-needle machine, but is stronger.

Fig. 4868.



Book-Sewing Machine.

In machines for sewing with waxed threads, a lamp warms the wax and thread. See also SHOE-SEWING MACHINE and Plate LIX.

The cylinder sewing-machine has a cylindrical work-holder for sewing seams on sleeves, trousers, water-hose, boot-legs, leathern buckets, and other tubular works.

3. The sewing-machine for books is shown in Fig. 4868.

The folded sheets are placed on the table *B*, which is capable of a sliding movement, and are compressed between it and a removable press (not shown), while slots are cut in their backs to receive the thread.

The sheets are then transferred to the inclined table *o*, the table *B* is slid up to the needle-guide *C*, and the sheets are one by one transferred to the table *B* and opened. A thread unwound from a spool at one side of the machine is inserted within the fold of the sheet behind the needles *G*, which are so adjusted as to pass into the slots previously made in the paper, and have their hooked upper ends turned backwardly. By depressing the treadle *E e* the needles are drawn downward, carrying the thread with them through the openings in the back; the sheet is then turned over, a second sheet placed upon it, opened, the needles again passed through by the upward movement of the treadle, a turn of the thread is taken around one of the end needles, forming a loop, and it is then passed beneath the hooks of the other needles as before. In sewing the next sheet, the same process is followed, a turn being taken around the needle at the opposite end, and so on until the whole are completed. In special cases this method is departed from, and needles of various forms, seen at the foot of the cut, are employed. Sometimes cords *i* are used instead of the end needles. The lower ends of these are secured to plates on the guide-bar *C*, their upper ends being tightened by a pin *m* around which they are passed. *D* is the needle-holder bar; it has a series of slotted plates *f*, through which the needles pass; a plate beneath these engages in one of the notches of the needles, which are there held by springs f^2 until firmly secured by a movement of the lever d^2 operating an eccentric which clamps the needle-holders firmly against the needles. As the pile of sheets grows higher, the needles are raised by turning the lever d^2, permitting them to be lifted until a lower notch engages with the locking-plate, when they are again clamped. *C* is the guide-bar provided with a series of slotted plates *h*, through which the needles pass.

The lower figures illustrate differently shaped needles employed in various kinds of work.

Patent No. 150,495, Thompson and Parkhurst, May 5, 1874, preserves the general features of the *sewing-table*. The signature is notched, placed upon the needles, the lacing-thread is passed, and the signature folded. The lifters are then thrown forward by means of levers, a cam operating the frame, thus holding the sewed signatures firmly in position. At the same movement of the lever the cam operates upon a slide, which is kept tightly pressed against the cam by the pressure of the right-angle lever upon a bearing-bar by means of a spring. The movement of the right-angle lever by this means operates the bar and throws pivoted hooks around the needles, holding them firmly in position for the operation of the thread-carrier. A backward movement of the lever withdraws the hook from around the needles and the lifters from over the signatures, and permits the addition to the partly sewed book of another signature. See also No. 151,507, Parkhurst and Thompson, June 2, 1874; No. 36,428, Tanner, September 9, 1862; No. 74,948, Smyth, February 25, 1868; No 91,175, Smyth, June 8, 1869.

Adaptations to book-sewing of the ordinary Sewing-Machine. No. 124,694, Palmer, March 19, 1872, machine for sewing pamphlets. No. 135,662, Palmer, February 11, 1873, book-sewing-machine. The signature, held between two slotted clamping-plates, is moved by them through shafts, connecting-levers, and the Geneva stop-motion intermittingly under the needle of an ordinary sewing-machine, the upper plate, upon the completion of the sewing, being released from cam-pressure and raised by a spring; a presser-foot operated by suitable cam holding it in contact with bed of machine during return movement of clamps. Two signatures can be alternately sewed (upon the forward and backward movements of the clamps), being separated by guides, one of which has a knife-edge to cut the thread, said clamps being moved longitudinally to place them into the path of the needle

See also Patent, No. 105,329, Hall, July 12, 1870.

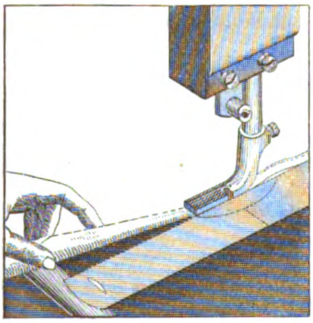
Stabbing-Machines. No. 114,286, Glass, May 2, 1871; No. 116,757, Reynolds, July 4, 1871.

Sew′ing-ma-chine′ At-tach′ment. The term is held to include those devices which are attached to a machine to enable it to do some special duty other than plain sewing.

They are enumerated in the following list, and some of the principal ones are shown in Figs. 4869–4876. It may be mentioned that the cuts are illustrative of the work, and but little variation is shown in the mode of attaching to the machine. There are, however, many modes of attaching the devices; to the table, to the head of the machine, making it a part of the presser-foot, attaching it to the needle-bar, etc. See the articles in the following list under their respective heads in the body of the work.

Basting-machine.
Binder (Fig. 4875).
Bobbin.
Bobbin-winder.
Braider (Fig. 4877).
Button-hole marker.
Cloth-plate.
Corder (Fig. 4876).
Creaser.
Embroiderer (Fig. 4877).
Embroidering-machine.
Feeder (see page 2122).
Feller (Fig. 4871).
Gage (see page 2122).
Gatherer (Fig. 4874).
Guide.
Hemming-guide.
Hemmer (Figs 4869, 4870).
Marker.
Needle.
Needle-setter.
Needle-sharpener.
Needle-threader.
Plaiter.
Presser-foot.
Quilter (Fig. 4873).
Ruffler (Fig. 4874).
Sewing-machine gage.
Sewing-machine needle.
Shuttle.
Spool-holder.
Stitch.
Stitching-machine.
Thread-cutter.
Threader.
Thread-guide.
Thread-waxer.
Tuck-creaser.
Tuck-marker (Fig. 4872).
Waxer.

Fig. 4869.

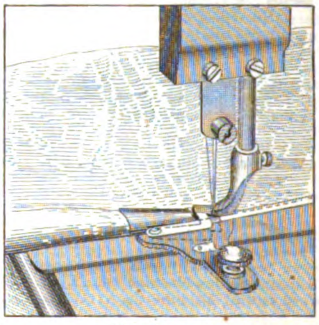


Narrow Hemmer.

Fig. 4869 is for turning and sewing narrow hems. It is, in the case illustrated, made a part of the presser-foot. It is a curved tongue, narrowing toward the needle-hole, turning the raw edge and the hem at the same time that the feed draws the goods to the needle.

Fig. 4870 is a device adapted to make broader hems. It is shown as attached to the bed-plate, and acts in a manner similar to the former.

Fig. 4870.

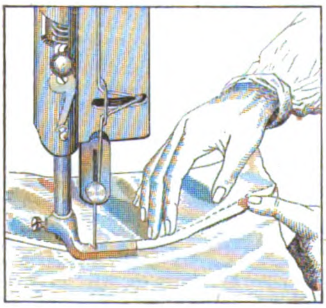


Wide Hemmer.

Fig. 4871 is a *feller*. It turns over the two raw edges at the same time, ready for the needle, which stitches them down.

Fig. 4872 is a *tuck-marker*. It has a guide attached to the cloth-plate of the machine, and attached to the side of the bed is an arm that gages the distance between the tucks, and also carries the under marker. The cloth is folded over this arm. The upper marker is attached to the needle-bar, and one tuck is marked while the needle is sewing the former one.

Fig. 4871.

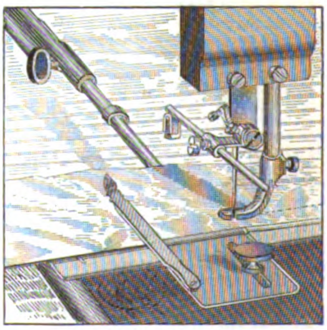


Feller.

Fig. 4873 is a *quilter*. An arm fastened to the head of the machine carries an adjustable guide, which runs in the seam last made.

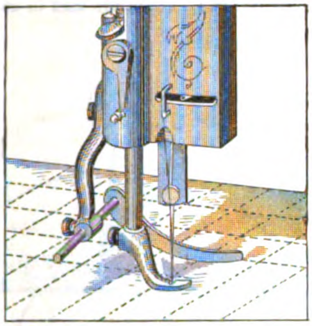
Fig. 4874 is a *gatherer* and *ruffler*. It has two blades, between which the strip to be ruffled is passed, while the cloth to which it is to be sewed is run beneath the lower blade. These blades are attached to a vibrating cam-lever, which is pivoted to an arm on the presser-bar. The blades are advanced by the upward motion of the needle-arm carrying the gather past the needle-hole, and are retracted by the downward motion of the needle-arm slipping back over the goods, as the needle sews the gather. The unsewed full edge makes the ruffle.

Fig. 4872.



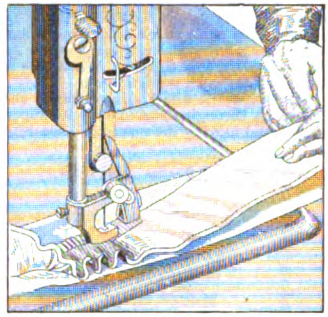
Tuck-Marker.

Fig. 4873.



Quilter.

Fig. 4874.

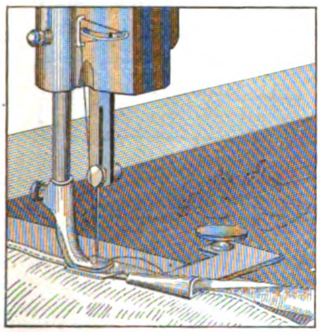


Gatherer and Ruffler

Fig. 4875 is a *binder*. It is a double tapering scroll, the upper part only of which is shown. The edge of the cloth is passed into the slit on the side of the scroll, and the binding entering at the large end follows the form of the scroll, and its edges, as they pass out of the scroll, lap against the goods; the decreasing size of the scroll also turns under the raw edge of the goods.

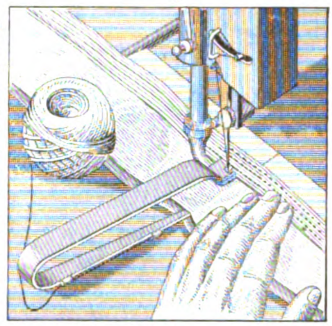
Fig. 4876 is a *corder*, attached to the presser-foot, which has grooves in the bottom running in the direction of the seam. The cord is passed from the ball through two eyes on the projecting arm of the corder, then at a right angle through another eye immediately in front of the groove in the presser-foot; as it passes through the groove a seam is run alongside it.

Fig. 4875.



Binder.

Fig. 4876.

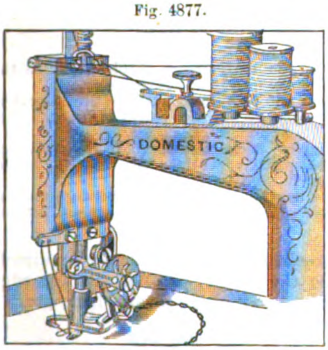


Corder.

Fig. 4877 is an *embroiderer*. The forked arm attached to the needle-bar carries a pawl that slides freely over the face of the ratchet on the downward movement of the needle, but engages and turns the rack as the needle ascends. In the back of the ratchet is a star-shaped cam-groove, which operates the upper end of the lever that reciprocates in the slots in the embroidering arms, causing them to cross the threads after each stitch, and the next descent of the needle stitches them thus.

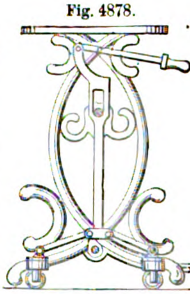
Sew'ing-ma-chine' Cast'er. Sewing-machine casters are so made as to be brought into use when the machine is to be rolled over the floor, and thrown out of use to give the machine steadiness when working.

Fig. 4877.



Embroiderer.

Fig. 4878.



Caster for Sewing-Machine.

In Fig. 4878, the casters have vertical movement, and are operated by levers actuated by cams on the treadle rock-shaft when the said shaft is raised by the hand-lever. The casters may be depressed in relation to the machine, so as to support it when it is to be moved.

In Fig. 4879, caster-wheels attached to supports passing through fixed guides attached to the legs of the frame are raised by cams operated by levers and connecting links to raise the frame from the floor. See also list, page 2115.

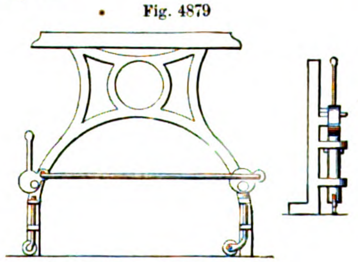
Sew'ing-ma-chine' Feed. The device or devices for moving the cloth or other material intermittingly forward or past the needle. They may be subdivided as follows, namely: —

Clamp. Two parallel bars or jaws, material confined between them, and moved by pawl or pinion engaging teeth or clamp. See patent to Greenough, February 21, 1842. Fig. 4848.

Baster, or Pin-plate. A flat, horizontally moving plate, with sharp pins projecting from one edge. Material crowded on these pins and carried by plate. See patent to Howe, September 10, 1846. In Fig. 4880, *A* shows this feed: the needle *a* vibrates in a vertical plane, carrying the upper thread *e*; *d* is one of the points projecting from the edge of the baster-plate, which traverses horizontally across the path of the needle, and carries the cloth *h*, which is suspended from the row of points *d*, one only of which is shown by this side elevation. *n* is the shuttle-mover. In both these cases a seam longer than the clamp or plate cannot be sewn without stopping the machine and readjusting the clamp or plate and cloth.

Pin-wheel, or Bolt. An annular ring, disk, or endless belt, moved intermittingly forward in one direction, and provided

Fig. 4879

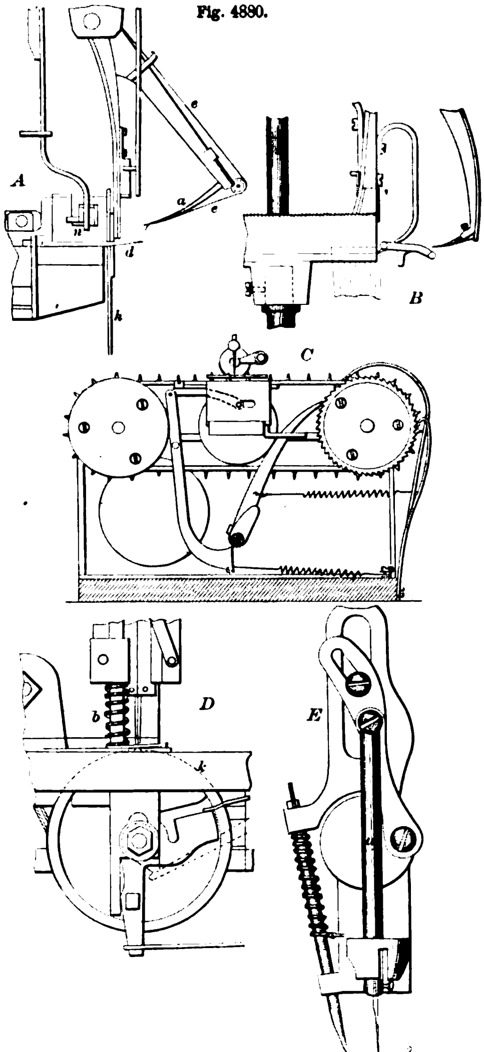


Sewing-Machine Caster.

with pins to enter and move the material for a seam of any desired length without stopping. The rotating-pin surface may move horizontally about a vertical axis and sustain and move material, as in patent to Blodgett and Lerow (*B*), October 2, 1849, or may move about a horizontal axis and carry the material over a horizontal cloth-supporting surface, as in patent to Bachelder (*C*), May 8, 1849. When pins are used it is difficult to sew other than a straight seam.

Wheel-feed. A wheel with periphery roughened or serrated, projecting through a slot in a cloth-supporting surface, and engaging and moving the material. See Singer, August 12, 1851.

Fig. 4880.



Sewing-Machine Feed.

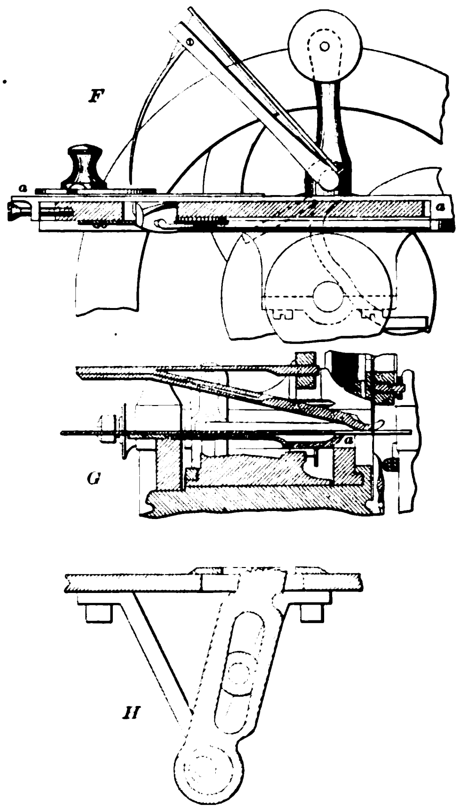
In *D* the rough-surfaced wheel is shown at *k*. The material is pinched between the wheel and the presser-foot *b*, and advanced by an intermittent motion in the intervals of the downward strokes of the needle.

Needle, or Awl. A reciprocating needle or awl, vibrated when in the material (see patent to Johnson, March 7, 1854), or moved horizontally through a horizontal movement of the block or head in which the needle or awl reciprocates. See patent to Townsend, April 8, 1862, or McLean, 1869, shown at *E*, in which the needle-bar *a* is oscillated.

Two-motioned. A horizontally reciprocating rough-surfaced dog or plate *a* engages the material at all times, carries it intermittingly to the needle, and while the needle is in the material moves back to take a new stroke. See Wilson, November 12, 1850, shown at *F*.

Four-motioned. A rough-surfaced dog or plate *a*, so moved as to rise against the material, move horizontally, fall from the material, and move back to its original position. See Wilson, June 15, 1852. See *G*, Fig. 4881. Commonly used in most

Fig. 4881.



Sewing-Machine Feed.

sewing-machines. *H* is a modification of this, in which the path of motion is elliptical instead of quadrangular.

Thread. A plate or arm pressing against the thread next to and moving the material forward. See patent to Stedman, November 27, 1855.

Upper feed. A feeding device located above the cloth-supporting surface and engaging upper side of material. See patent to Wickersham, April 19, 1853.

Each of the above has numerous minor subdivisions of detail, but the number of kinds of feed in actual use is quite limited.

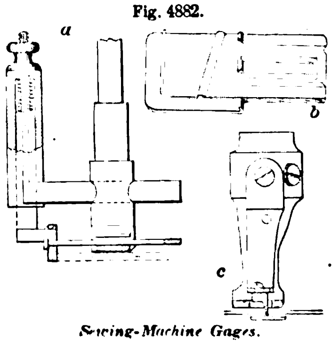
Sew'ing-ma-chine' Gage. A device for directing the goods to the needle, parallel with the edge of a selvage or edge, or with a previous hem, etc.

a is an edge-gage attached to the presser-foot and adjustable laterally.

b is attached to the cloth-plate in advance of the needle-hole.

c is a device to enter a seam to insure the parallelism of a second seam.

Fig. 4882.



Sewing-Machine Gages.

Sew'ing-ma-chine'

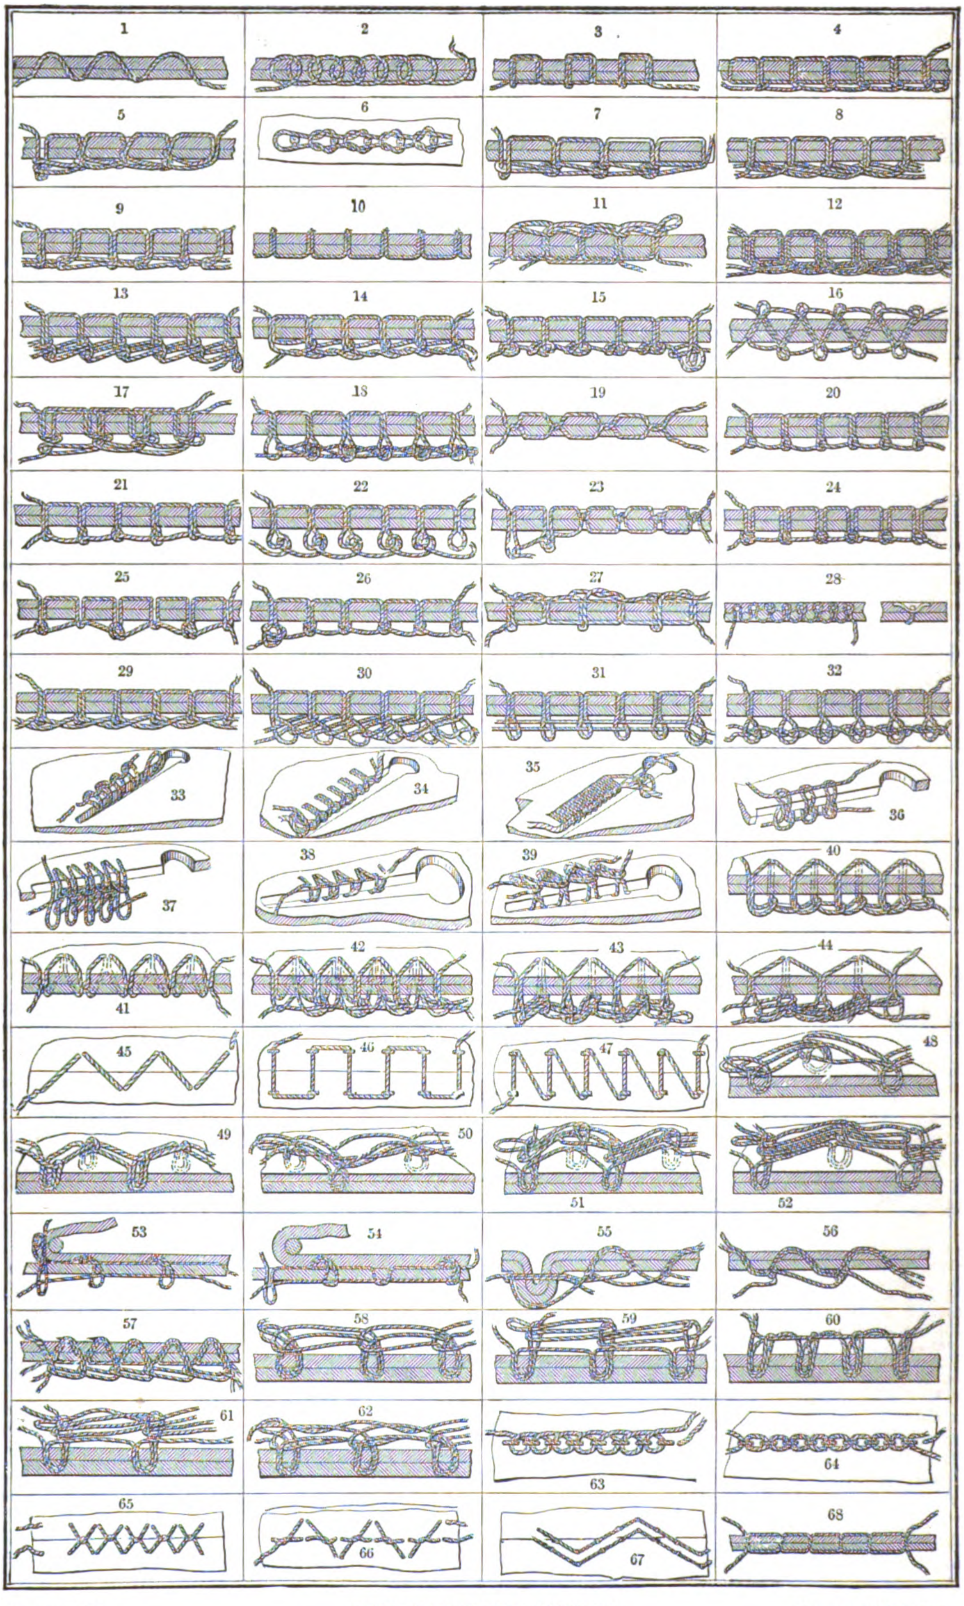


PLATE LVII. SEWING-MACHINE STITCHES. *See pages 2123, 2124.*

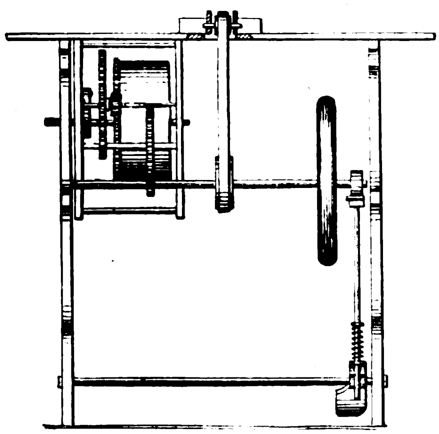
Hook. A rotating or reciprocating device beneath the table of a sewing-machine, to catch the needle-thread and open it while the succeeding stitch is made through the loop thus afforded. Or, which loops the needle-thread while the bobbin or shuttle containing the lower thread is passed through said loop. It is known as the *Wheeler and Wilson hook*. See Fig. 15, Plate LVI., and also Figs. 4861, 4862.

Sew′ing-ma-chine′ Mo′tor. A spring or engine attached to a sewing-machine as a driver. The example shows the application of a coil-spring as the moving power for ordinary domestic use. A friction-

Fig. 4883.



Spring Motor for Sewing-Machine.

roller and a brake, governed by a foot-lever, are employed to adapt the motion of the machine to the work.

There are many other modes, besides the one usual in factories, which consists of band connection with the usual shafting driven by an engine. See list, page 2115.

The electro-magnetic automotor of M. Cazal may be hidden under a footstool. Four of Bunsen's elements are sufficient for driving an ordinary sewing-machine at a stated cost of sixteen cents per day.

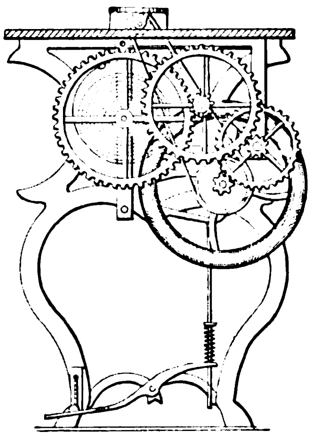
The apparatus itself has an iron pulley with an externally toothed rim, which revolves freely within a metallic ring, toothed similarly to the pulley, but on its internal surface, so that the points of the teeth of the pulley face and approximate to those of the outer circle. An insulated wire runs over the pulley, which thus becomes a magnet whenever an electrical current is run through it, and ceases to be so from the very instant that the current is interrupted.

While the current from the battery is active, each of the teeth of the pulley attracts its opposite on the rim; and if the current were to remain constant, each of these would remain *in situ*, and no motion would be imparted to the wheel; to avoid this, a commutator, which is set in motion by the motor itself, regulates the passage of the electrical current through the wire and renders it intermittent. As soon as the apexes of the teeth have placed themselves into opposition, the current ceases and the teeth on the pulley proceed onward, when a fresh current forces them into a second opposition with the next set on the rim, and so on indefinitely, producing a very satisfactory rotary motion. The power being symmetrically disposed around the axis and in each tooth, there is but little friction on the bearings and no noise produced. The speed can be varied at will, and pressure on a knob or button causes instant stoppage.

Sew′ing-ma-chine′ Nee′dle. These are straight or curved, and with an eye near the point. The straight needle is upon a bar which reciprocates in a straight path; the curved needle is upon an arm which oscillates on an axis. (See SEWING-MACHINE.) In one machine for making sewing-machine needles, the blank is grasped by one of a series of jaws and presented progressively to a cutter, a grooving tool, a similar tool to groove the opposite side, a punch, and a polishing-wheel. The jaws are upon sliding stocks, which are moved radially by a cam-groove, to cause the necessary rotation in the presentation of the blank to the tools.

In the usual method the blanks, in length from 1½ to 2 inches, are (1) cut from a coil of wire, and (2) a groove is simultaneously made on each side for the reception of the thread. Successive operators perfect the needle.

The first cuts out the eye with a punch operated by a treadle; the second straightens the blanks by tapping them on a steel block with a mallet; the third takes a dozen or so between the thumb and forefinger, and rounds them by a twirling motion while held against a rapidly moving emery belt; the fourth points them upon an emery wheel by a very similar manipulation; a fifth polishes out the grooves, using two rapidly rotating brushes, one of brass wire and the other of bristles; a sixth stamps the size or number on each needle.



A number are then placed in a muffle, the muffle in a furnace, and when heated to a cherry red, the needles are emptied into a vessel of whale-oil. This renders them extremely brittle; they are tempered by placing them on a heated copper plate and keeping them in continual motion until they turn to a light straw-color, when they are permitted to cool.

The revolving brushes are again used to remove the scale and impart a final polish. The eyes are then polished by drawing rapidly backward and forward over threads charged with polishing paste; in the case of straight needles, they are now ready for packing, after being straightened by a few blows of the hammer, but those for the Wheeler and Wilson, Grover and Baker, and other machines requiring curved needles, are bent to a curve of seven inches' radius before being packed.

Sew′ing-ma-chine′ Stitch. See the following, represented in Plate LVII.

Single Thread.

1. The ordinary *running*-stitch used in basting.
2. The *back* stitch.
3. The *fast* stitch.
4. *Chain*-stitch.
5. *Coiled*-loop chain-stitch.
6. *Knitted*-loop chain-stitch.
7. *Knotted*-loop chain-stitch.
8. Loop *enchained* by second alternate stitch.
9. Each loop locks and enchains alternate loops.
10. *Staple* stitch for waxed threads.

Two Threads.

11. *Double-needle* chain-stitch.
12. Double-thread chain; stitch two threads, one needle.
13. Double-looped stitch. Grover and Baker.
14. Chain with interlocking thread.
15. Under-thread through its own loop.
16. Two needles penetrate fabric from opposite sides.
17. Two needles working from the same side of the fabric.
18. Doubly interlocking loop.
19. *Lock*-stitch. Singer, Wheeler and Wilson, Weed, Wilson, Howe, Domestic, Florence.
20. Coil in needle-thread.
21. Double coil in needle-thread.
22. Coil in shuttle-thread.
23. Double coil in shuttle-thread.
24. Knot-stitch; every stitch knotted.
25. Knot-stitch; every other stitch knotted.
26. Knot-stitch (different knot).
27. Shuttle-thread drawn up to form embroidery.
28. *Wire*-lock; thread locked by wire.

Three Threads.

29. Two shuttles, each locking alternate loops.
30. Double loop with interlocking third thread.
31. Two shuttle-threads locking each loop.
32. Two shuttle-threads intertwining and locking each loop.

Button-hole Stitches.

33. Single thread. Loop of needle-thread drawn up over the edge and locked by needle at its next descent.
34. Two threads. Bights of needle-thread, above and below, extend to the edge of the fabric, and are locked by shuttle-thread.
35. Two threads. Needle penetrates back from edge, its loop passed to, and interlocked by, the needle at its next descent over the edge, and this second needle-loop locked by shuttle-thread.
36. Shuttle-thread drawn up over the edge of the fabric to the line of the needle-thread.
37. Needle-loop through the fabric locked by needle-loop over the edge, and second loop locked by second thread.
38. Two threads. Edge of fabric covered by shuttle-thread.
39. Third thread laid under the stitch at the edge of the fabric.

Fancy Stitches.

40 to 47. Various of above-described stitches made *zigzag*.
48 to 52. *Single-faced* or *straw-braid*, *zigzag*, or *herring-bone* stitches.
53 to 62. *Single-faced* or *straw-braid* stitches.
63 to 67. *Embroidering* stitches.
68. *Saddler's* stitch.

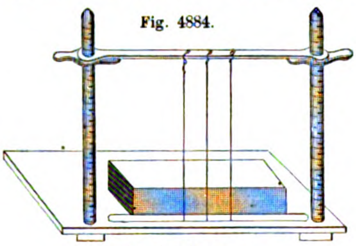
For the above selection of illustrations of stitches and the systematic description, the writer is indebted to Mr. G. W. Gregory, of Boston.

The *sampler* stitch is a hand stitch used in berlin work on canvas or perforated paper. One stitch crosses the other at right angles, forming a small cross.

Sew'ing-press. The frame with stretched vertical cords, against which the backs of the folded sheets of a book are consecutively laid and sewed.

Three or more grooves are sawed into the back of the pile of sheets, so that they shall fit to the inside of the same number of cords in the frame. The sewer takes a sheet, fits the grooves to the cords, and half opens the folded sheet in the middle. A stout thread,

Fig. 4884.

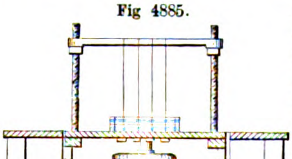


Sewing-Press.

its end first firmly fastened, is passed by means of a needle over the first cord, then along the inside of the fold of the sheet to the second cord, over that and along the fold to the next, where it is secured by a *hitch*; then another sheet is laid on, and the same operation is repeated in reverse order until a pile of sheets as high as the sewer can conveniently reach has thus been sewed to the cords. Such a pile will probably contain a dozen volumes. The cords are long enough to allow an inch or two at each end, when the volumes are separated; these serve to fasten the sheets into the covers. The sheets thus sewed together are now ready to receive their covers.

Sew'ing-ta'ble. A table or bench at which signatures of books are sewed to the cords or bands by which they are fastened together, and also secured in the cover. *Sewing-press.*

Fig 4885.



Bookbinder's Sewing-Table.

In the example, the bench is vertically adjustable on the supporting table, so as to be lowered by a screw as the pile of sheets rises; this maintains the top of the latter at a convenient hight for sewing.

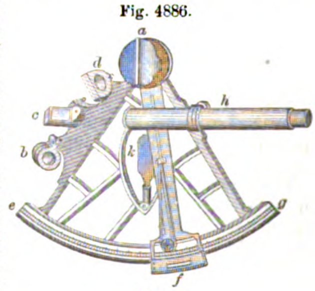
Sex'tant. *a.* An instrument for measuring angles; it resembles a quadrant, but has an arc of 60°. Arabian astronomers are said to have had a sextant of 59 feet 9 inches radius, about A. D. 995.

One of this kind was used by Tycho Brahe at his observatory in the island of Huen, A. D. 1550. These were supported vertically by a wall or pillar, were not reflecting instruments, and consequently were only capable of measuring angles up to 60°.

b. The reflecting sextant is particularly useful on shipboard, being conveniently held in the hand, and equally well adapted for measuring the altitudes of celestial objects in order to obtain the latitude and local time, or for lunar observations; that is, measuring the angular distance between the moon and the sun, or between the moon and a fixed star or planet, for the purpose of ascertaining the longitude. It is an improved form of the quadrant of reflection, invented by Newton in 1699 (see QUADRANT), and is capable of measuring angles of 120° or more. It consists of a frame, generally of metal, but sometimes of ebony, stiffened by cross-braces, and having an arc embracing about 65° of a circle. This is divided into double the number of degrees actually embraced between the two extreme graduations of the arc, as the fixed and movable glasses, owing to the double reflection, only form with each other an angle equal to half the angular distance between the two objects observed, one of which is seen directly and the other by reflection from the index-glass.

"Its flat surface is called the plane of the instrument. *e g* is the arc or limb, reading by the vernier attached to the movable radius *a f* to 30″, 20″, 15″, or 10″, as the case may be. *a* is the silvered index-glass, provided with screws for its adjustment. At *b* are the fore-shades or screens of colored glass. *c* is the horizon-glass, the lower half of which is silvered, and which also has screws for its adjustment. At *d* are the back-shades or screens of colored glass. *h* is the telescope, useful for obtaining accurate results, but not an essential feature of the instrument. *a f* is the movable radius, carrying at one end the index-glass, and at the other end a vernier. This is read by a microscope. Slow motion is imparted to the radius by a tangent-screw. *k* is the handle, attached to the back of the frame. The principle of the sextant depends on the practical application of the following theorem in optics: 'When a ray of light, proceeding in a plane at right angles to each of two plane mirrors which are inclined to each other at any angle whatever, is successively reflected at the plane surfaces of each of the mirrors, the total deviation of the ray is double the angle of inclination of the mirror.'" — G. CHAMBERS.

Fig. 4886.



Sextant.

When observing altitudes the instrument is held perpendicularly to the horizon, in observations in the plane of the line joining the two objects. On shore an ARTIFICIAL HORIZON (which see) is used; at sea the navigator is compelled to rely on the natural horizon.

In taking noon observations at sea to determine the latitude, the observer takes his place shortly before meridian, and turning down one or several of the shades to prevent his eye being injured by the glare, directs the telescope or sight-tube to the sun, moving the index so as to bring its reflected image to coincide with the sea horizon; as the sun rises, he gradually advances the limb, clamping it and using the tangent-screw for this purpose, as the sun's path becomes more nearly horizontal, and slightly rocking the instrument from side to side to insure that it is in a vertical plane at the moment when the sun attains his greatest hight. The reading of the limb at the moment when the sun begins to dip is noted, and a very simple calculation, adding his declination derived from the "Nautical Almanac" to the true zenith distance obtained by observation, gives the latitude.

Meridian altitudes of the moon, a planet, or a fixed star may also be employed for this purpose.

Observations for local time are taken when the sun or other object is rising or falling most rapidly; the calculations for this

are more complicated. When ascertained, it is compared with the time at Greenwich or other meridian, as indicated by a chronometer on board; the difference of time turned into arc at the rate of four minutes of time to one degree of arc, gives the longitude of the place of observation. Calculations for determining the latitude by double altitudes taken out of the meridian, and those for longitude by lunar observation, are still more complex, and observations of the latter frequently require the observer to assume a very inconvenient position.

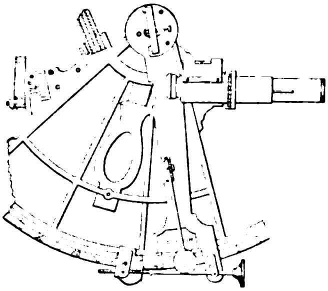
In observations on shore with the artificial horizon, the true altitude of the object is doubled by the reflection of its image from the mercurial surface; the apparent angle must therefore be divided by two.

Besides the uses of the sextant as specially adapted to the purposes of the astronomer and navigator, it is also used by the surveyor for measuring angles and for filling in the detail of a survey when the theodolite is used for the long lines, and laying out the larger triangles.

The Box-sextant (which see) is a small instrument specially contrived for this purpose.

The spirit-level sextant, invented by Mr. George Davidson, of the United States Coast Survey, is designed for observing the altitudes or depressions of celestial and other objects, dispensing with both the natural and artificial horizons. It consists of an observing tube, on top of which is a spirit-level, the bubble of which is viewed by reflection from a plane mirror just below it, forming an angle of 45° with the axis of the instrument. As the level is too near the eye for distant vision, a convex lens is inserted in the tube between the mirror and the eye. This is longitudinally adjustable, to adapt it to the vision of different observers. The mirror occupies but one half the tube, in order that the observed object may be seen direct, and for the same reason the lens embraces only a semicircle. In making observations the sextant is held in the usual manner, the object and the eye in the same vertical plane, and by moving the vernier arm the image of the object is brought into the same horizontal line with the image of the cross-wires in the tube at the same time that they bisect the image of the bubble. The reading on the graduated limb of the instrument shows the angle of elevation or depression of the object. For night observations the bubble must be illuminated. This may be done by means of a lamp, or by a vial filled with phosphorus in oil, which, when air is admitted by withdrawing the stopple, will afford light sufficient for the purpose.

Fig. 4887.



Sextant.

Sex'to. (*Bookbinding.*) A size of book made by folding the sheets into six leaves each.

Sex'to-dec'i-mo. (*Bookbinding.*) A size of book in which each signature is folded to contain sixteen leaves. *16mo.*

Shab'rack. (*Menage.*) (Fr. *shabraque*; Hungarian, *csabrág*; from Turkish, *tshâprâk.*) The cloth or housing of a military saddle.

Sgraf'fi-to. (*Fine Arts.*) A style of picture in which a white ground is chipped or worked away to expose a black sub-surface.

Shack'le. 1. (*Locksmithing.*) The hinged and curved bar (*a*) of a padlock by which it is hung to the staple.

2. (*Nautical.*) *a.* A link (*b*) in a chain-cable which may be opened to allow it to be connected to the ring of the anchor or divided into lengths, usually fifteen fathoms. It consists of a *clevis*, *bolt*, and *key*. Used for the chains also.

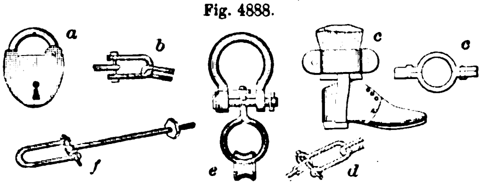
b. A ring on the port through which the port-bar is passed to close the port-hole effectually.

c. The clevis, secured by a pin and bolt to the shank of an anchor, and to which the cable is bent; used in place of the old-fashioned anchor-ring.

3. (*Railroading.*) A link for coupling railroad-cars, being engaged by the pin of the respective draw-heads. See Car-coupling.

4. A fetter or gyve (*c*) for the ankle of a prisoner, consisting of a ring riveted around the small of the leg and connected by a chain to a similar shackle on

Fig. 4888.



Shackles.

a, padlock-shackle.
b, chain-shackle.
d, rafter and tie-rod shackle.
e, swivel-shackle.
f, shackle-bolt.

the other leg, to a ring-bolt in the floor or wall of the cell, or otherwise.

5. (*Husbandry.*) The usual connection of the *double-tree* to the forward end of the plow-beam. A *clevis.*

6. (*Carriage.*) The iron by which the bed or body of a carriage is made to rest upon the spring-bar.

Shack'le-bar. (*Railway.*) A coupling bar or link of a railway-car.

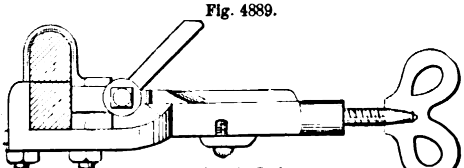
Shack'le-bolt. 1. A bolt having a shackle or clevis on the end (*f*, Fig. 4888).

2. One passing through the eyes of a clevis or shackle.

Shack'le-crow. (*Nautical.*) A bolt-extractor with a shackle instead of a claw.

Shack'le-jack. (*Vehicle.*) An implement for attaching the thills to the shackle on the axle where an anti-rattling box of india-rubber is used. The

Fig. 4889.



Shackle-Jack.

jack forces backward the eye of the thill-shackle, compressing the rubber sufficiently to bring into line the bolt-holes of the two parts of the shackle.

Shade. 1. A colored glass in a sextant or other optical instrument for solar observations.

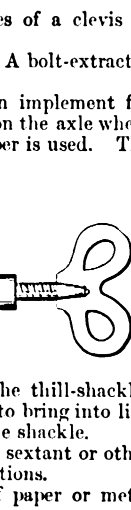
2. *a.* A hollow conic frustum of paper or metal surrounding the flame of a lamp, in order to confine the light within a given circular area.

b. A hollow globe of ground glass or other translucent material, used for diffusing the light of a lamp or burner. A clean glass globe obstructs about 12 per cent of the light; when ornamented with cut flowers or figures, about 24 per cent; a globe ground all over, about 40 per cent.

3. A device for protecting the eyes from the direct rays of the sun or artificial light.

4. A window-curtain to exclude light.

Fig. 4890.



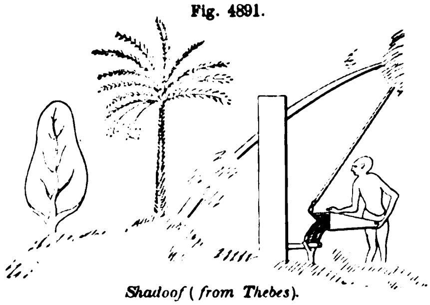
Curtain-Hook.

Shade-hook. A hook for holding a curtain-cord.

Sha-doof'. The *shadûf* (Arabic) is the oldest

known water-elevating machine, and is about equivalent to our swing-pole and bucket arrangement. It is found represented in monuments of as early date as 1432 B. C., and has been in use in Italy in all

Fig. 4891.

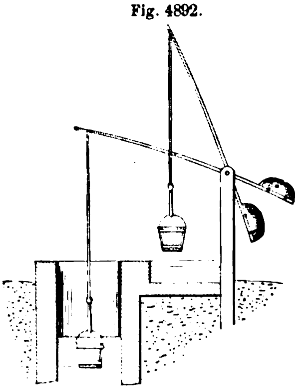


Shadoof (from Thebes).

times, ancient and modern. It is still very common along the Nile, being employed in raising water for irrigation. It has not been adopted for irrigating purposes in other countries to any great extent, though a few are to be found in Palestine.

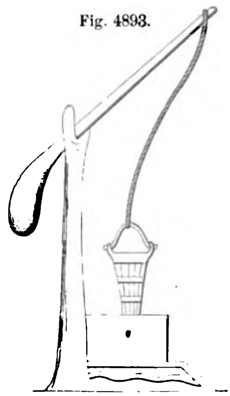
The Egyptian system was to divide the allotments of land into shallow beds, with a raised wall or ridge of soil around each. The water was then turned from the common ditch into the *squares* successively, the dividing wall of earth being scraped away by the foot.

Fig. 4892.



Modern Shadúf.

Fig. 4893.



Anglo-Saxon Draw-Well.

"For the land [Canaan], whither thou goest in to possess it, is not as the land of Egypt, from whence ye came out, where thou sowedst thy seed, and wateredst it with thy foot, as a garden of herbs; but the land, whither ye go to possess it, is a land of hills and valleys, and drinketh water of the rain of heaven."

Fig. 4892 is the modern Egyptian shadúf. A weight is tied on to the end of the raising-pole to counterbalance the full bucket. A simpler way, not unfrequently employed in this country, is to employ a sapling with a thick, heavy butt.

The *draw-well*, shown in Fig. 4893, is from a MS. of the fourteenth century in the Harleian MS., England, No 1,257.

Shaf-fer-oon'. (*Architecture.*) A form of molding. See CONGE.

Shaft. (*Mining.*) A perpendicular or slightly inclined pit. It is sunk by digging or blasting. In treacherous ground it is lined by curbs, called *tubbing* or *cribbing*. A longitudinal division is a *brattice*. It is used for access to the mine, for ventilation, for the pump-stocks, for the removal of ore or coal. Jutting ledges in the shaft are *scarcements*.

The term *sinking* is applied to a *shaft*; *driving*, to a *drift*, *adit*, or *gallery*.

The names of shafts refer to the specific uses; as,

Engine-shaft, that in which the hoisting apparatus works. Also known as the *winding*-shaft or *working*-shaft.

The *ventilating*-shaft (which may also be a working-shaft) is known as an *upcast* shaft, for ascent of air, or a *downcast* shaft for descent of fresh air. When these two are one shaft, they are divided by a *brattice*.

An *air*-shaft is a ventilating-shaft.

Pumping-shaft, for the pump-stocks and rods for drainage of the mine.

Ladder-shaft, by which the miners descend and ascend to and from the working.

Trial-shaft, an experimental boring to ascertain the presence of minerals or water, or the extent of a *field*.

The *timbering* or lining of a shaft is by means of *props*, *sills*, or *bars*, and *cleading*. The specific names depend upon position, and some of the terms apply to drifts and galleries.

The *props* are struts or posts, either vertical or raking, and are usually of round timber.

The *sills* or *bars* are horizontal timbers resting on the props.

The *cleading* are boards which form the casing, and for whose support the props and bars form a frame.

The square ends of the props abut upon the sills and bars, and are prevented from slipping by a peculiar form of spike, called a *brob*.

The depths of the shafts in Cornish mines are reckoned from the level of the *adit*.

Until lately the greatest depth yet attained was in the now abandoned Kuttenberg mine, in Bohemia. Some of the Newcastle mines are 1,800 feet deep.

The depth of a mine in a mountainous country, such as the Tyrol, Bohemia, or Mexico, being reckoned from the surface, gives no indication of actual depth in respect of sea-level.

The mine at Joachimsthal, in Bohemia, is 2,120 feet, but the surface of the ground at the mouth of the shaft is 2,388 feet, above sea-level.

The Valenciana mine in Mexico is 5,910 feet above the level of the sea, and its deepest workings are 4,274 feet above that level.

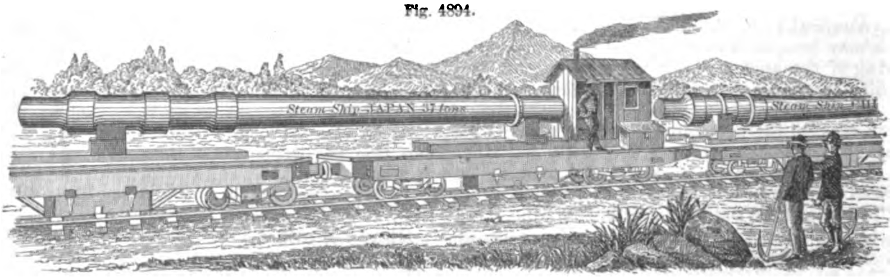
A boring at Minden is 2,231 feet deep, of which 1,993 feet are below the level of the sea.

These depths are much exceeded by some in the Comstock lode, Nevada.

2. (*Vehicle.*) One of the bars between a pair of which a horse is hitched to a vehicle. A *thill*.

The Egyptian chariots were always drawn by a pair of horses yoked to the end of a pole or tongue. The Lydians, it is said, attached several poles to their chariots, and placed a horse between each pair. This was using shafts. It is probable that

Fig. 4894.



Paddle-Shafts for Pacific Steamers (en route for San Francisco by Union Pacific Railway).

1,000 years before Alyattes shafts were used by the nomadic nations in moving camp. In its primitive form, we see it used by the North American Indians of the present day. A couple of poles are slung by girths and breast-straps, one on each side of a horse, and the load is placed on the trailing ends of the poles. Some time in the dim past an axle and a pair of low wheels was contrived, and this makes the modern dray. Perhaps a pair of gudgeons, driven into the end of a log, were made to support the shaft near their midlengths. The question of priority as between rollers and wheels must be decided in favor of the former on the ground of probabilities. The first we know of the civilized nations of antiquity, the dwellers upon the Nile and in the land of Mesopotamia, they had gorgeous chariots and other excellent appointments.

The Roman *cisium* was a kind of gig for rapid traveling, and was perhaps drawn by one horse between shafts. One old monument seems to represent it that way.

3. (*Machinery.*) *a.* That part of a machine to which motion is communicated by torsion, as the shaft of a fly-wheel, a paddle-shaft or screw-shaft of a steam-vessel, the crank-axle of a locomotive.

The shafts for the steamers "Japan" and "China," weighing respectively 78,520 and 68,400 pounds, were transported from Bridgewater, Mass., where they were manufactured, to San Francisco, by rail. Two trucks were required for each. Their arrangement is shown in Fig. 4894.

A *counter*-shaft is one between the main shafting and the machine.

b. A rod supported in hangers or bearings suspended from the ceiling or beneath the floor of a workshop, by which motion is communicated to various machines from the prime motor. See SHAFTING; HANGER.

4. *a.* The portion of a chimney above the roof. A *stack*.

b. The chimney of a furnace.

5. (*Architecture.*) The body of a column.

6. *a.* The handle of a weapon or tool. A *haft*.

b. The forward, straight part of a gun-stock.

7. The helve of a tilt-hammer.

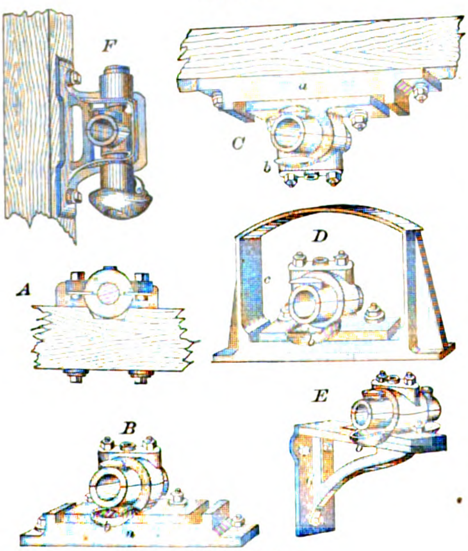
8. The interior space of a blast-furnace.

9. (*Weaving.*) A long lath at each end of the heddles of a loom.

10. An arrow.

Shaft-al′ley. (*Shipbuilding.*) A passageway between the after bulkhead of the engine-room and the *shaft-pipe*, around the propeller-shaft, and affording a means of access thereto.

Fig. 4895.



Pillow-Blocks.

Shaft-bear′ing. Fig. 4895, *A*, clamp-block.

B, pillow-block resting on cast-iron wall-plate *a* and provided with oil-dish *b*.

C, the same, inverted; used for carrying the head-shafts of long lines of shafting.

D, the same built into a wall and protected by an arched wall-box *c*.

E, pillow-block secured to a knee *d* attached to the face of a wall. *b*, Oil-dish.

F, post-hanger, fastened to an upright or pillar. See also STEP; SPINDLE.

Shaft-coup′ling. 1. A device for connecting together two or more lengths of a revolving shaft by shaping the ends into flat surfaces or bearings, which are held together by a strong iron bush or coupling-box.

A common but unyielding coupling (*a*, Fig. 4896) is formed by fitting and fastening the square ends of the sections of coupling into sockets in an iron block.

Another mode (*b*), which admits of some yielding when the shafting is not perfectly in line, consists of serrated disks on the adjacent ends of the sections of shafting. These have sufficient play to permit the joint to bend a little when the shafting is out of line.

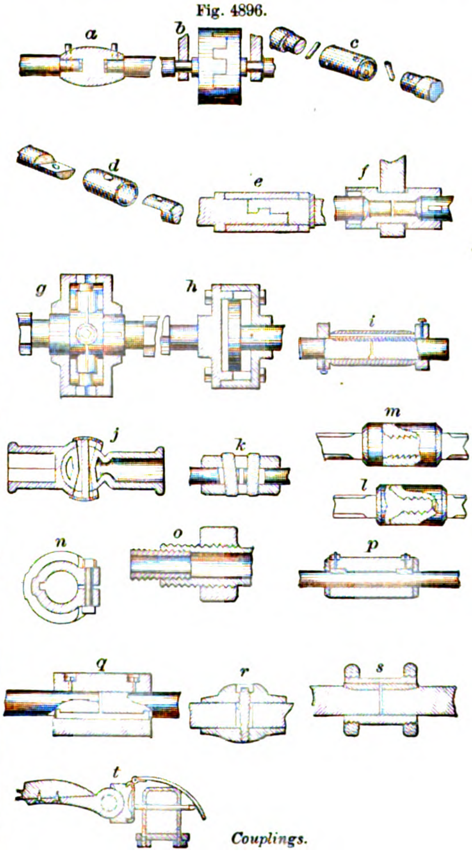
A form of coupling (*c*) consists of a cylindrical box with pins at right angle engaging the ends of the sections of shafting. By allowing a little play to the parts, this partakes in a degree of the principle of the *gimbal*.

The lap-joint coupling (*d*) is formed by reducing the ends of the shafting to a semi-cylindrical form, so as unitedly to form a cylinder, which is inclosed by a coupling-sleeve secured by a pin or key.

By scarfing the ends together (*e*), they are protected against longitudinal displacement, without depending on the strength of the pin.

Murray's coupling-box (*f*) rests in the hanger, and has sockets at the ends for the reception of the ends of the shafting and the

Fig. 4896.



Couplings.

keys, which are at right angles to each other. A slight play is allowed in the fitting of the parts.

In another form of coupling (*g*) a cross is interposed between the boxes, which are at the end of each section of the shaft. Each arm of the cross has a screw at its end; two of these receive motion from two projections on one box, while the other two bear against two similar projections on the other box, causing the two shaft-sections to turn together. This coupling performs to a limited extent the function of a universal joint, but requires a bearing at each end of every section.

One form of friction-coupling (*h*) consists of a pair of boxes, inclosing disks on the ends of the adjacent sections of shafting. Between the disks is a planchet of leather, which is compressed to such an extent, by screwing up the bolts, as to cause the motion of one shaft to be communicated to the other. If a violent strain occur beyond the coupling, greater than that for which the coupling is intended, one of the disks will slip on the leather.

Mattison's friction-coupling has caoutchouc on the abutting faces of the wheels on the respective sections of shafting. The frictional contact of the india-rubber, when the wheels are brought into contact, causes them to revolve together when motion is imparted to one of them.

i. Hawkins. T-headed keys occupy longitudinal slots in the abutting ends of the shafts, and are held in place by a sleeve.

j. Wheeler. A ball on one shaft enters a socket on the end of the other, and is held there by a key passing through a slot in the ball and retained in place by a cap, allowing a certain degree of rolling motion.

k. Fox. The ends of the shafts are made tapering, are inserted within the tubular coupling, and held by keys.

l. Lecky. The end of one shaft has a screw-threaded tenon of peculiar shape, which enters a correspondingly threaded cavity in the enlarged end of the other.

m. Lecky. Is similar in general to the foregoing, but the screw-threads are flat on the sides which have to resist a pulling force.

n. Briggs. This coupling has an opening on one side, permitting it to expand somewhat to readily receive the shafts, upon which it is compressed by bolts and nuts; a recess on the opposite side receives one half of a key, fitting counterpart slots in the ends of the two shafts to compel their simultaneous rotation.

o. Bolles. Is particularly designed for well or other tubular shafting. The ends of each tube are threaded both internally and externally; the former threading receives an internal thimble connecting the sections, and the latter an exterior nut which covers the joint.

p. Gray. Two or more pawls within a sleeve are, by means of binding-screws, pressed into nicks in the shafts so as to prevent their independent rotation.

q. Baum. A coupling-fin provided with studs enters slots in the two sections of the shaft, and is retained in place by a sleeve held to the sections by screws.

r. Ruggles. The coupling-box is in two parts, which are drawn together by a bolt having differential screw-threads adapted to corresponding internal threads in each half of the box between which the shaft is clamped.

s. Light. The ends of the shaft-sections are slotted to receive a key which is held by a split sleeve secured by a nut screwed on to each of its ends.

2. (*Vehicle.*) A device for securing the thills of a carriage to the axle-tree. One form is shown at *t*. A THILL-COUPLING (which see).

Shaft-coup'ling Jack. (*Vehicle.*) An implement for bringing the shaft-eye and axle-clip into

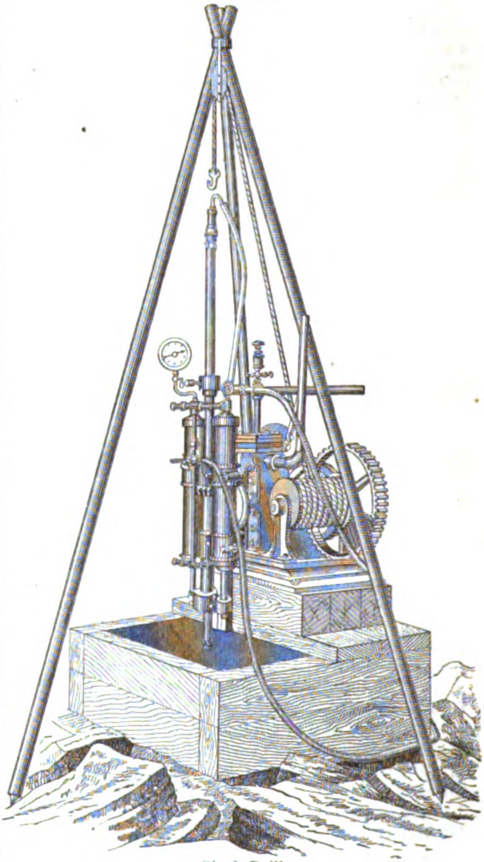
Fig. 4897.

Shaft-Coupling Jack.

apposition, so that the bolt will pass through the two portions. It is used where an anti-rattling block of caoutchouc is placed between shaft-eye and axle.

Shaft-drill. A rotary drilling-machine, armed with diamond-points, for boring vertical shafts. It is supported on a framing over the shaft, and the drill is rotated by bevel-gearing operated from two steam or compressed-air cylinders. The drill-holder may be lifted and lowered by a tackle suspended from shears when it is desired to substitute a shorter for a longer drill-rod. See page 697.

Fig. 4898.



Shaft-Drill.

Shaft-fur'nace. (*Metallurgy.*) One in which the ore, in a state of division, is dropped down a chimney through the flame. See ROASTING-FURNACE; SILVER-MILL. See also Fig. 3420, page 1571.

Shaft'ing. (*Machinery.*) The principal means in a machine-shop for the transmission of power. It serves to convey the force which is generated in the engine to the different working-machines, for which purpose it is provided with drums and belts, or else cog-wheels firmly keyed on.

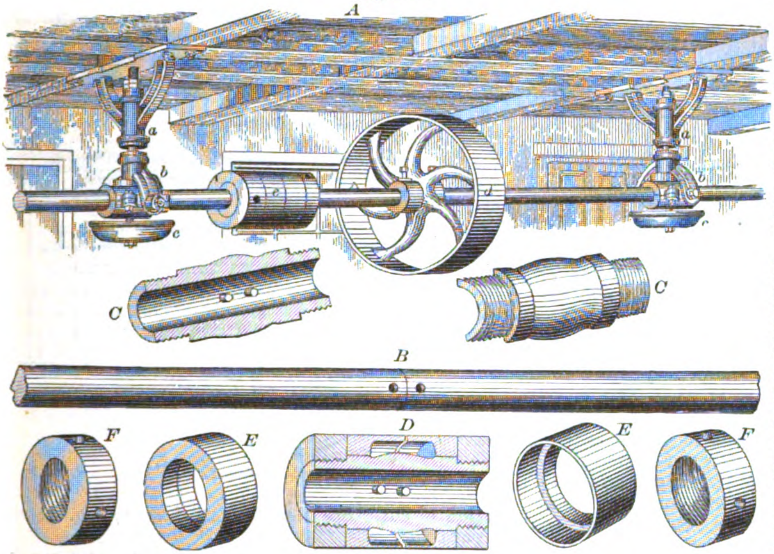
Horizontal shafts are known as *lying;* vertical, as *upright.*

Their *stiffness* resists *flexure* and *torsion;* their *strength* resists *fracture.* The *stress* is the power tending to break them.

A, Fig. 4899, represents a portion of a line of shafting attached to beams of a ceiling. The hangers *a* are secured to the beams by bolts, and are provided with swivel-boxes *b*, facilitating adjustment and keeping of the shafting in line. These are adjustable in hight by bolts and nuts. *c* are oil-drip cups, *d* a pulley, and *e* the coupling which unites two lengths of the shaft. These are shown in contact, but disconnected, at *B*. *C C* are inside and outside views of the coupling proper. *D*, one half of the coupling, with its appendages complete. *E E* are the *thimbles*, and *F F* the securing nuts. The cylindrical interior of the coupling is bored with a *shim* between the two sections, so as to allow something for compression or hug. These are placed over the butting ends of the shaft-sections, and secured thereto by pins, if desirable; the thimbles or cone-rings are slipped over them, and the nuts *F F* screwed on with a spanner, binding the whole together.

In Fig. 4900, *A* shows another pattern of shafting, with hangers and appurtenances. The journal-box *a* is held between two pintles or stems *b c*, the ends of which are concave, those of the

Fig. 4899.

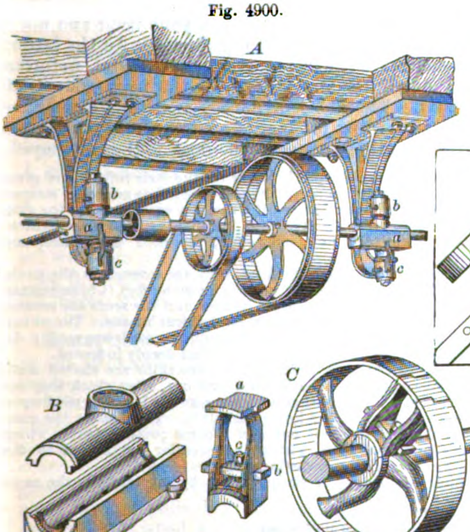


Shafting.

box bearing being convex, so as to form a species of ball and socket joint, and allow the box to adjust itself to the alignment of the shaft.

The box is self-lubricating; the oil, after being drawn up

Fig. 4900.

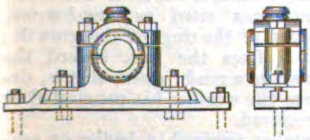


Shafting.

from a reservoir below by the rotation of the shaft, and performing its office, is again returned to the reservoir, the drip-cup being dispensed with.

Fig. 4901 is a cast-iron plummer-block; it is lined with gun-metal or Babbitt metal, and supported on a wall-plate having snugs between which the block fits, and is adjusted in line with the shaft by cotters driven between its ends and the snugs.

Fig. 4901.



Plummer-Block.

Fig. 4902 is a form of flexible shafting, avoiding the use of gearing. See also FLEXIBLE COUPLING, page 882.

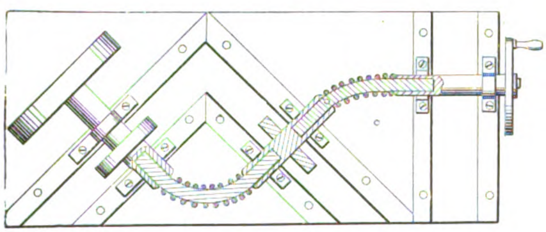
It sometimes becomes necessary to take down a section of shafting, drive out keys, and remove couplings, merely to slip on a pulley. To obviate this necessity, pulleys have been made in sections, to be keyed together on the shafting.

Preferable to this is an arrangement by which a small section of hub and rim are made removable.

In Wheeler's (*C*, Fig. 4900), one or more of the arms of the pulley are enlarged, or divided, admitting a piece shown at *a*, a casting separate from the pulley, and easily fitted to the latter by the file. This supplementary piece has a section of the hub embracing one half of the shaft. It engages with the rim of the pulley by a parallel cut, divided in the center at right angles. This form of division, however, is not material. The piece is held in place by a bar *b*, passing through the true arms of the pulley and the false arms of the segment, and held in place securely by a set-screw *c*. Instead of this arrangement the bar may be a single key without set-screw. There is no set-screw to mar the shaft, and no key in the hub of the pulley or key-way on the shaft to be cut. Most of the fitting required is at the rim, as the hub portion may be cast accurately enough and the key may be forged to fit.

Shaft'ing-box. An inclosed bearing for a shaft. In the example, the shaft has its bearing in a perforated box within an outer shell filled with oil.

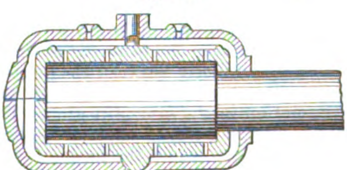
Fig. 4902.



Universal Shafting.

Shaft'ing-hang'er. A suspended bearing for a shaft. In the example, the body of the hanger is made hollow, and cores of different sizes are used in the space, so that one pattern may be used for several sizes of shafts. A self-oiling apparatus is com-

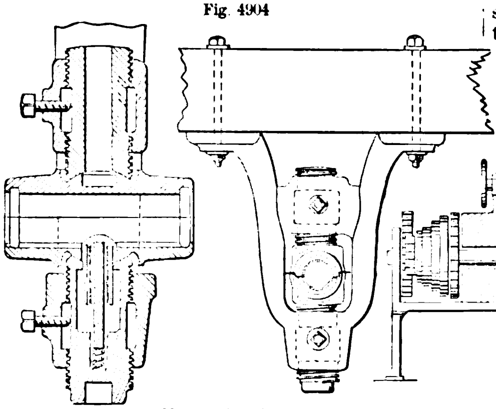
Fig. 4903.



Shafting-Box.

bined with a ball-and-socket hanger, so as to bring the reservoir of oil close to the lower side of the

Fig. 4904



Hanger for Shafting.

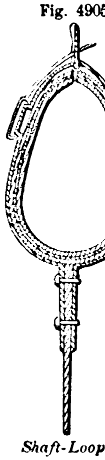
shaft and at the same time in the center of the bearing. See also HANGER, page 1059.

Shaft-jack. (*Vehicle.*) An iron attaching the shafts to the axle. See SHAFT-COUPLING JACK.

Shaft-loop. (*Harness.*) The ring of leather suspended from the gig-saddle to hold the thill or shaft.

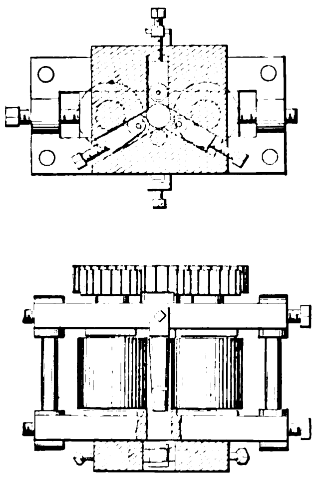
Shaft-pipe. (*Shipbuilding.*) The pipe or tube in the stern of a vessel through which the propeller-shaft passes in-board. In wooden vessels it occupies a hole bored through the *stern-post* and *dead-wood.* In iron vessels it passes through a hole in the stern-post and through frames with circular arcs, which form bearings.

Fig. 4905.



Shaft-Loop.

Fig. 4906.



Machine for straightening and rounding Shafting.

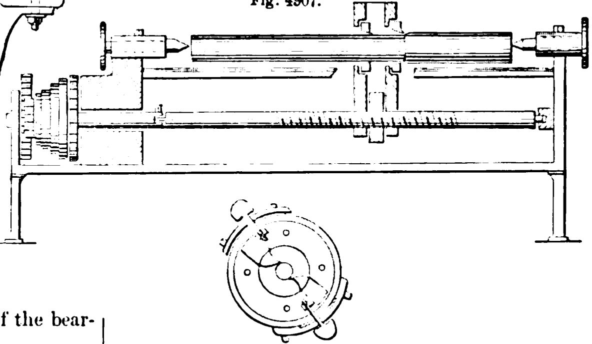
Shaft-straight'en-er. A machine for rolling rods for shafting to take the bend out of them. The shaft is fed longitudinally between the pressure-rollers *B B*, which are geared to a common wheel, so as to have rotation in the same direction. The feed-rollers are upon the ends of adjustable slides, and are placed obliquely to cause the feed.

A hydraulic press for this purpose is shown at *F*, Plate XXV.

Shaft-tug. (*Harness.*) The loop depending from the harness-saddle, and which holds up the shaft that passes through it.

Shaft-turn'er. A lathe for turning long rods for shafting. The shaft is held between two tail-centers and dressed off longitudinally by a series of annular cutters secured to a slide-rest. The shaft may be rotated, in which case the cutters in the annular holder will be modified to suit the direction of cut. See also DUPLEX LATHE, Fig. 1803, page 763.

Fig. 4907.



Shaft-Turning Lathe.

Shag. (*Fabric.*) *a.* A cloth with a coarse, rough nap.

b. Another name for *plush.* A shaggy pile-cloth of various materials.

c. The *pile* of velvet, fustian, plush, velveteen, etc.

Shag'ging. (*Knitting-machine.*) Giving a lateral motion.

Sha-green'. Shagreen is a parchment and not a leather, though it is usually classed with the latter. Its conception and production are Oriental, Astracan and Asiatic Russia being still the main sources of supply. The hides of horses, asses, and camels are concerned in its production, and it is said that only a strip from the crupper to the neck is thus employed.

The strips are steeped in water till the hair softens and gives readily, when it is removed by scraping; they are again steeped and worked by the flesher till all matter extraneous to the skin is separated, and the skin itself is reduced to the proper thickness. They are now moistened, mounted on frames, and stretched.

Being spread upon the floor, they are covered on the grain side with the seeds of the *alabuta* or goose-foot (Chenopodium album). A covering of felt is laid on, and the seeds are pressed into the skin by trampling or mechanical means. The skins, still bound in the frames, are dried till the seeds are readily detached. They are now dry, horny, and deeply indented.

Being placed on a padded horse, the skins are shaved until the indentations are shallow and uniform, after which they are steeped in hot water, then in a hot alkaline lye, and piled upon one another while in a hot, moist state. This causes the compressed parts to swell out and become protuberances, which form embossed balls, giving the peculiar appearance to the leather by which it is distinguished.

Shagreen is dyed of various colors by substantially the same means as morocco.

Red by cochineal.

Blue by the cold indigo vat.

Black by solution of tannin, followed by sulphate of iron.

Green by sal-ammonia and copper filings.

Imitation shagreen is made by passing the leather between rollers, in contact with a copper plate suitably indented.

Shake. 1. (*Coopering.*) A shook of staves and headings. See SHOOK.

2. *a.* A *wind-shake* is a crack in standing timber from exposure, strain of wind, or the like. The faults of timber are sometimes cited as ring-*hearted*, cracks in the direction of the rings of the growth; *wind-shaken*, cracked from the bark toward the pith, otherwise known as a rend; *doted*, that is, decayed in spots where the weather has penetrated or a wound has been received.

b. A crack in lumber received in drying or seasoning.

Shake-wil'ly. (*Cotton-manufacture.*) A *willy* or willowing-machine for cleaning cotton, preparatory to carding.

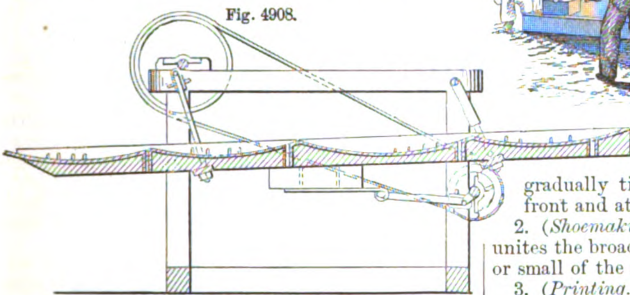
Shak'ing-frame. 1. A frame turned by a crank or otherwise, and having sieves arranged upon it; used in graining powder.

2. (*Metallurgy.*) A form of buddle or sieve used in sorting ores.

Shak'ing-ma-chine'. A shaking or rotating box in which articles are agitated, to grind or polish them by mutual attrition upon each other, with or without the aid of extraneous helps, such as sand, emery, or graphite. See TUMBLING-BOX.

Shak'ing-ta'ble. (*Metallurgy.*) A form of separator in which the slimes or comminuted ores are agitated in the presence of water. In the example, the rocking table has lateral concavities furnished with agitating pins and vertical discharge-openings. The table has longitudinal and vertical motion from cranks on two shafts having different speeds, and connected by a belt over pulleys on said shafts.

Fig. 4908.



Shaking-Table.

Shal'li. (*Fabric.*) A twilled cloth made from the hair of the Angora goat.

Shal-loon'. (*Fabric.*) From *Chalons*, in France. A kind of worsted stuff, formerly used.

"In *blue shalloon* shall Hannibal be glad."
SWIFT.

Shal'lop. (*Nautical.*) *a.* A light fishing-vessel with two masts and lug or fore-and-aft sails.

b. A *sloop*. A one-masted, undecked, fore-and-aft rigged vessel.

c. A boat for one or two rowers.

Sham'bles. (*Mining.*) Shelves, stages, or benches on to which the ore is thrown successively in raising.

Sham'my. Properly *chamois*. A kind of soft leather, originally prepared from the skin of the chamois goat; but that usually met with is made of common goat or sheep skins, prepared so as to give great pliability and softness. It is much used for cleaning and polishing carriages, silverware, glass, and fine varnished work. See CHAMOIS; TAWING.

Sha-moy'ing. (*Leather.*) A process in preparing skins. See CHAMOIS.

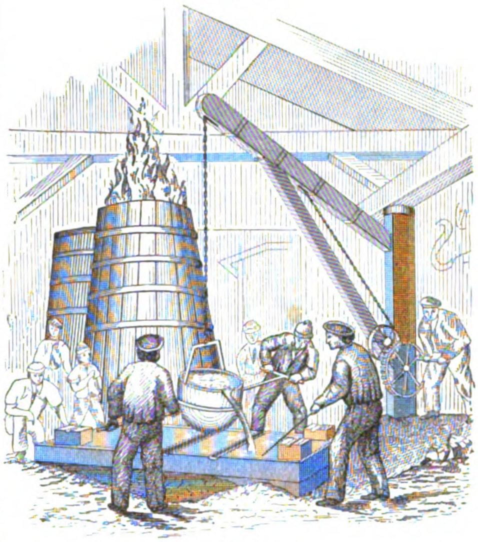
Sham-poo'ing Ap'pa-ra'tus. A barber's wash-basin and rose-syringe, for washing the hair and scalp.

Shank. 1. (*Founding.*) A large ladle to contain molten metals; it is managed by a straight bar at one end, and a cross-bar with handles, called the *crutch*, at the other end, by which it is tipped to pour out the metal.

They are made of various sizes, from those handled by two men to those containing several tons, and slung from a crane.

Nasmyth, of Manchester, England, has added to the pivot of the large crane-ladle a tangent-screw

Fig. 4909.



Shank.

and worm-wheel, by which it may be gradually tilted by a man standing directly in front and at any convenient distance.

2. (*Shoemaking.*) That part of the shoe which unites the broad sole and the heel; beneath the arch or small of the foot.

3. (*Printing.*) The body of a type.

4. (*Lock.*) The stem of a key, between the *bow* and the *bit*.

5. (*Nautical.*) The stem of an anchor, connecting the *arms* with the *stock*. See ANCHOR.

6. The straight portion of a hook.

7. The tang of a case-knife or chisel.

8. The part of a nail between the head and the taper of the point.

9. (*Tools.*) The part of a tool by which it is held or fastened, or to which the handle is attached.

10. The eye on (not through) a button.

11. (*Architecture.*) The space between two of the channels in the Doric triglyph.

Shank-cut'ter. (*Shoemaking.*) A machine or tool for cutting shanks for boots and shoes.

Shank-ir'on. (*Shoemaking.*) *a.* A former for the shank of a boot or shoe.

b. An iron plate placed between the leather portions of a boot-shank, to stiffen it.

Shank-last'er. (*Shoemaking.*) A tool for fitting the upper leather over the shank of the last. The edge of the leather is gripped by the jaw, by screwing down the handle, and a leverage obtained by the pivoted fulcrum on the surface of the last.

Fig. 4911 consists of two levers which are crossed and jointed together so as to form two jaws and two handles; the inner parts of the jaws are made of leather, the edges extending beyond the toothed or spurred ends of the same.

Shank-paint'er. (*Nautical.*) The chain or chain and rope which fastens the *shank* and *flukes* of an anchor to the side of a vessel, abaft the cathead, while the *ring* and *stock* are secured to the *cat-head* by the *cat-head stopper*.

Shanks. Flat pliers used by lens-makers, for *shanking* or *nibbling* the edges of pieces of glass, to reduce them to circular form before the grinding and polishing processes commence.

Fig. 4910.

Shank-Laster.

Fig. 4911.

Shank-Laster.

Shank-wheel. (*Shoemaking.*) A tool to ornament the shank of a boot or shoe.

Shape. 1. A matrix or mold.

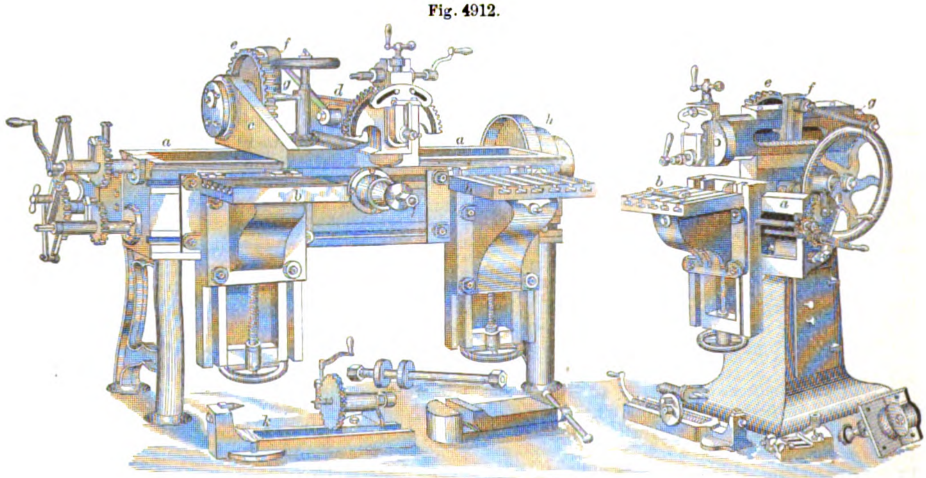
2. A piece of metal, roughed out as nearly as may be to the shape it will assume when finally forged and finished.

Shaped Fab'ric-loom. A loom for weaving corsets, skirts, etc.

Shap'er. 1. (*Metal-working.*) A form of planer in which the work is placed on a mandrel or dogged to a stationary bed, while the tool-stock is reciprocated. The machine has assumed many forms, and is one of the comparatively late additions to the machine tools of the shop.

Fig. 4912 shows two sizes of this machine-tool. The longer has 6 feet length of bed; length of stroke, 14½ inches; will plane a length of 5 feet, and weighs about 5,000 pounds. The smaller machine has a length of stroke of 9½ inches, and will plane a length of 16 inches. Each has quick-return motion and circular feed. The bed *a* is grooved on the front side, so as to afford hold for the tables *b b* for holding the work; the tables are adjustable vertically, horizontally, and independently. On the bed *a* is the tool-bed *c*, in which the tool-head *d* slides transversely of the bed by means of spur-wheel *e*, crank *f*, and pitman *g*, driven by gearing from the band-wheel *h*. The extent of this motion is variable, being determined by the distance of the crank-pin from the axis of the crank. *i* is an arbor upon which is shaped circular work. A hole is bored in the object, and it is then dogged on the arbor, which is slightly rotated between each reciprocation of the tool, thereby feeding the work to the cutter. The result is the planing of a surface curved in a plane at right angles to the motion of the tool. The machine is much used for shaping objects in which the circular form is not complete, and they cannot, therefore, be turned

Fig. 4912.



Shapers (Large and Small Sizes).

in a lathe. The motion of the tool is in a line parallel with the axis of the arbor.

k shows upon the floor a bed with a pair of heads having centers upon which small work may be mounted, and the whole placed upon one or both of the tables *b b*. The mandrel in the attachment *k* is at right angles to the motion of the tool. This enables other kinds of shapes to be reached.

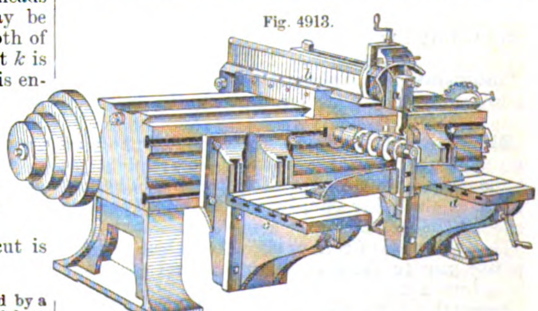
Adown the length of the bed *a* passes a feed-screw which moves the tool-bed *c* between strokes, when required. Depth of penetration of the tool and its angular presentation are obtained by rectilinear and circular adjustments of the tool-head.

The smaller machine on the right of the cut is similar in its mode of operation.

In the machine (Fig. 4913), the tool-holder *a* is carried by a sliding head *b*, to which reciprocating motion is imparted by a link arrangement. Plane work is placed on and adjusted by the tables *c d*; circular work is carried on the arbor *e*, the head *b* being kept stationary while the arbor is rotated.

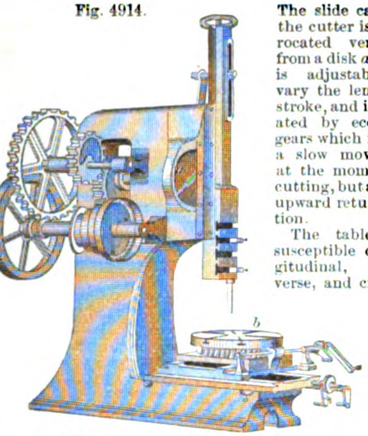
The machine (Fig. 4914) is used for paring, shaping, and slotting.

Fig. 4913.



Long-Bed Shaping-Machine.

Fig. 4914.



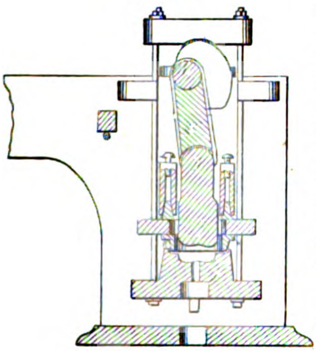
Shaping and Slotting Machine.

The slide carrying the cutter is reciprocated vertically from a disk *a* which is adjustable to vary the length of stroke, and is operated by eccentric gears which impart a slow movement at the moment of cutting, but a quick upward return motion.

The table *b* is susceptible of longitudinal, transverse, and circular horizontal motion to present the work, or to feed on any line of advance by combined movements of the rectilinear and tangent screws. See also ROUTING-MACHINE.

2. (*Sheet-metal Working.*) A striking or stamping machine for raising sheet-metal. In the example, the die and its bed-plate are raised against the clamp and plunger, the clamp being secured to a cross-plate which bears against adjustable springs. The die is secured to a cross-head, reciprocated by link attachment to a crank on the same shaft which carries the eccentrics giving the motion to the die. See STAMPING-MACHINE.

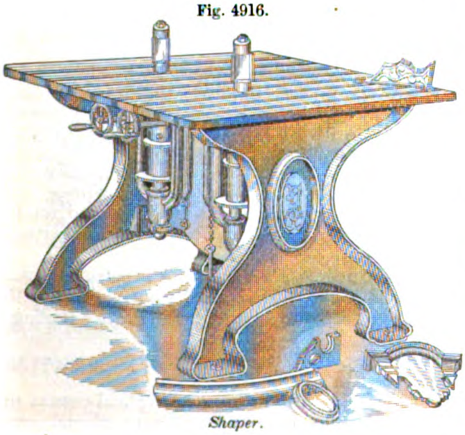
Fig. 4915.



Shaper for Sheet-Metal Ware.

3. (*Wood-working.*) A machine for cutting moldings and irregular forms. In that illustrated, the cutters are held by side and end pressure in cutter-heads at the top of vertical spindles. Various sized cutter-heads may be used. The spindle-bearings are connected, and are vertically adjustable by hand-wheels at the front of the machine. Safety-guards are provided over the cutters to prevent danger to the operator.

Fig. 4916.



Shaper.

Shap′ing. 1. (*Shipbuilding.*) As applied to the preparation of angle-plates for shipbuilding, *shaping* consists in *cutting* or *shearing* the angle-iron bars to the proper length (see SHEARS); *bending* them so as to give the proper figure to the molding edge (see BENDING; LEVELING-BLOCK; SWAGE); and *beveling* them (see BEVELING).

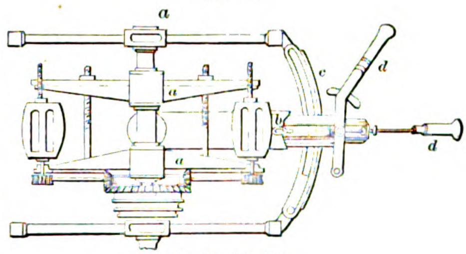
The shaping of plates consists in *cutting*, *planing* the edges, and *bending*.

Shap′ing-ma-chine′. 1. (*Metal-working.*) A machine-tool for working in metal. A planing-machine in which the object is dogged to a table with vertical and horizontal adjustment, or to a mandrel, and the tool above it has a reciprocating motion. See SHAPER.

2. (*Block-making.*) The shaping-machine *a*, Fig. 4917, turns the outside surface to form.

It consists of a large double wheel *a a* mounted on an axle, and having upon its rims 10 pairs of mandrels, by which 10 blocks are chucked. Of each pair, one mandrel forms a front center and chuck, by which the block is rotated, and the end of the other mandrel forms a back center on which the block turns. When the main wheel is rotated, the blocks revolve, each exposing the outside of one cheek to the action of the cutting-tool *b*, which traverses a segmental bar *c* by means of a slide-rest. The cutting-tool is moved by handles *d d* operated by the attendant.

Fig. 4917.

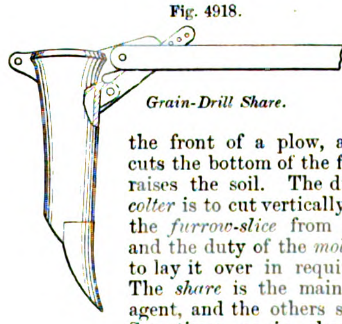


Shaping-Machine.

The outwardly exposed faces of the blocks having been dressed, the machine is stopped, and the whole series of blocks turned one quarter round by means of the central cog-wheel and the pinion connection to each of the mandrels. By resuming the rotation of the large wheel, the newly exposed face is dressed, and by a repetition of the process each of the four sides is brought to shape. *Shapes* are attached to the segmental guide, which control the form imparted to the faces of the blocks. One shape answers for the edges, and another for the cheeks. One handle keeps the tool to its work; the other has a roller, which runs against the shape and governs the curve.

Share. (*Husbandry.*) *a.* The sharp blade at the front of a plow, and which cuts the bottom of the furrow and raises the soil. The duty of the *colter* is to cut vertically to detach the *furrow-slice* from the *land*, and the duty of the *mold-board* is to lay it over in required order. The *share* is the main, effective agent, and the others subsidiary. Sometimes, as in shovel-plows,

Fig. 4918.



Grain-Drill Share.

the whole working portion is a share which cuts, lifts, and throws the furrow-slice.

Ransome, of Ipswich, England, patented the cast-iron share in 1785.

He patented the case-hardening of the upper edge in 1803, so that the share became self-sharpening.

b. The blade in a seeding-machine or drill, which opens the ground for the reception of the seed.

Sharp'en-er. See under the various heads: —

Knife-sharpener.	Scissors-sharpener.
Reaper-knife sharpener.	Steel.

Sharp'ie. (*Nautical.*) A long, sharp, flat-bottomed sail-boat.

Sharp-nail. A nail with a sharp forged point, used in some trades.

Sharps. The most pointed of the three grades of sewing-needles, — *blunts, betweens, sharps.*

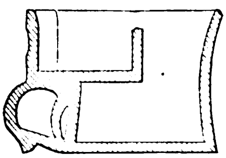
Shave. A drawing-knife. Sometimes a blade mounted in a stock, as a SPOKESHAVE, a DRAW-SHAVE (which see).

Shave-grass. A scouring-rush. A rough aquatic plant called the Dutch rush.

Shave-hook. A triangular plate of steel, with sharpened edges, used in scraping the surfaces of metal which are to be soldered. The object is to clean them from grease or soil, so that the solder may adhere. See SCRAPER.

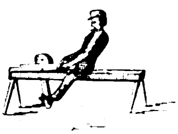
Shav'ing-cup. A cup with compartments for hot water and soap, for convenience in shaving.

Fig. 4919.



Shaving-Cup.

Fig. 4920.



Shaving-Horse.

Shav'ing-horse. (*Wood-working.*) A narrow bench or trestle on which the workman sits astride while shaving down work with the drawing-knife or spokeshave. It has a clamp, closed by pressure of the feet, for holding the work.

Shav'ing-mak'er. A machine for making wooden shavings for stuffing; also known as *excelsior.*

Shav'ings-con-duct'or. A device employed in wood-working establishments for removing the shavings, dust, etc., from the machines as fast as they are produced. It consists of a fan having tubes leading to each machine. The suction of the fan draws the refuse above referred to into a general delivery-tube, through which it may be forced to the furnace-room or deposited at any other suitable spot. See FAN-BLOWER, Fig. 1918.

Shav'ing-tub. (*Bookbinding.*) The box beneath the cutting-press to catch the shavings.

Shawl. An outer garment covering the upper part of the person; commonly used by ladies, but not unfrequently by men. In the latter case it represents the outer garment of the Scotch Highlanders, the plaid, which term in time has come to be applied to any kind of checkered goods similar in pattern to the tartan of which the Highlander's plaid was made.

Shawls are made of various materials, as wool, silk, crape, etc., plain or embroidered. The cheaper kinds are generally of wool, and are woven in the usual manner.

The English and French imitations of Cashmere or India shawls are sometimes made of pure Thibetian goats' wool, frequently of goats' wool and sheep's wool, and often wholly of the latter.

The manufacture of imitation Cashmere shawls was introduced into England about 1784 by a manufacturer of Norwich. He employed a warp of Piedmontese silk and a weft of worsted yarn, the design being afterward worked in by a process of hand darning. Norwich shawls were first produced entirely in the loom in 1805. Paisley then took up the manufacture and succeeded in producing successful imitation of Cashmere, using wool only, at very low prices.

In 1802 the manufacture was begun at Paris. The invention of Jacquard's loom, or at least its perfection by Jacquard, is said to have originated in this manufacture. The French imitations of India or Cashmere shawls still approach nearer the original than any others, and command a corresponding price. Those of Scotch manufacturers are, however, but little behind them, and are constantly improving. Great care is taken in the processes of scouring, dyeing, bleaching, and weaving. A Scotch shawl of the highest quality occupies a skillful weaver for a month or more, the weaving representing more than half the value of the shawl.

India or "camel's hair" shawls are made from the hair of a goat indigenous to the Himalayas and the highlands of Thibet, which has a fine curled wool beneath the coarse upper hair. In the spring, the goats are shorn, and the coarse hairs carefully picked out. The wool is washed in a solution of potash, and afterward in pure cold water, care being taken to avoid felting the fiber. It is spun by hand, a hard and wiry twisting of the fibers being avoided. For this purpose the spinners use for a spindle a ball of clay with an iron wire attached, and keep the finger and thumb smooth with soapstone powder. The wool is twice dyed, — before carding and after spinning.

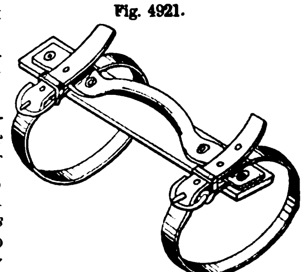
The pattern of an India shawl is worked in two very different ways. One method is to embroider it in a kind of needlework upon the material, and the other to work it into the web during the process of weaving. The latter method renders the shawl much more elegant and expensive. When this process is employed a number of skewers are used, sometimes of wood, but for the best work always of ivory, about the size of a common packing-needle. They are sharpened at both ends, and each skewer is covered with a different-colored thread. These are then worked according to a set pattern, stitch by stitch, into the web, as the weaving proceeds. As the process is very slow, no one person ever produces an entire shawl, the pattern being given out to the natives in patches or blocks, which are then by a similar method united in the common fabric. Of course but one surface of the product is presentable, the under side being a jumble of ends of threads without order or beauty.

The best are made in the vale of Cashmere, where the cost of a really fine shawl ranges from $250 to $500. Some of those which are worked for native princes are altogether too costly for export, being worth several thousand dollars.

Shawl-loom. A figure-weaving loom.

Shawl-strap. A traveler's pair of straps with handle to pack a shawl or blanket compactly.

Fig. 4921.



Shawl-Strap.

Shawm. (*Music.*) An ancient wind-instrument.

Sheaf. (*Husbandry.*) A bundle of wheat or other grain on the stalk, bound together. A number of *sheaves* standing together so as to be mutually supporting, forms a *shock* or *stook.*

Corn-fodder is sometimes bound in sheaves and mowed away, but more often the sheaves of two corn-shocks are stuck up together to form a fodder-shock.

Shear. A barbed fish-spear with several prongs.

Shear-grind'ing Ma-chine'. Fig. 4922 is a machine for grinding the blades of cotton and woolen shearing-machines. The spiral-knife cylinder *a* is mounted in bearings on the machine, and rotated against the grinding-roller *b*, renewing the sharpness of the knife-edges.

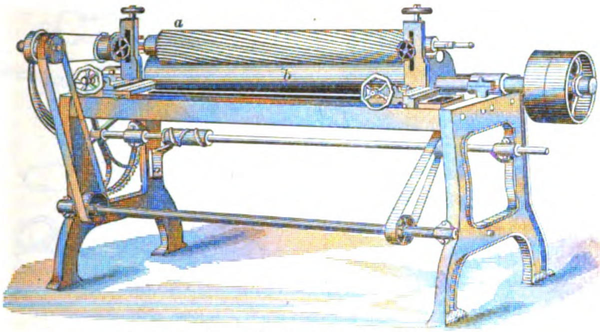
Shear-hook. (*Nautical.*) An instrument with prongs and hooks, placed at the extremities of the yards of fire-ships to entangle the enemy's rigging.

Shear-hulk. See SHEER-HULK.

Shear'ing. 1. The cutting of metallic plates and bars. See SHEARS.

2. (*Mining.*) The making of vertical cuts at the ends of a portion of an undercut seam of coal, serv-

Fig. 4922.



Shear-Grinding Machine (Curtis and Marble).

ing to destroy the continuity of the strata and facilitate the breaking down of the mass. The undercutting is called *holing.*

3. See SHEEP-SHEARS.

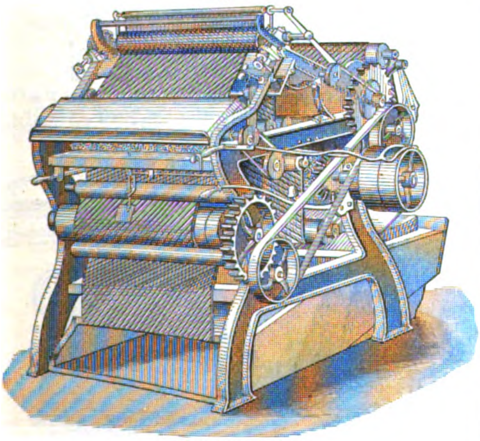
4. The cutting of the pile, nap, or fluff of cloth. See SHEARING-MACHINE.

Shear′ing-ma-chine′. 1. (*Woolen-manufacture.*) A machine through which cloth is passed after leaving the *gig-mill,* in order to shorten the nap and bring it to an even length so as to secure a smooth surface. This was formerly done by hand with a pair of shears. Machinery for the purpose was introduced, leading, of course, to riots, in England, at the beginning of this century. See CLOTH-SHEARING MACHINE, page 575.

One arrangement consists of a fixed semicircular rack, within or behind which is a cutting-edge, called a *ledger-blade,* and a large revolving wheel containing eight small cutting-disks, which, in contact with the ledger-blade, form a number of delicate cutting-shears; each cutting-disk is furnished with a toothed pinion working into the semicircular rack, so that as the large wheel revolves the disks acquire an independent rotary motion in addition to their motion with the large wheel. The machine may be made to travel over the cloth, or the cloth may be moved beneath the machine, which remains stationary.

In Curtis and Marble's machine (Fig. 4923), the cloth is wound from one roller on to another, passing over a fixed bar, which holds it up to the action of the

Fig. 4923.



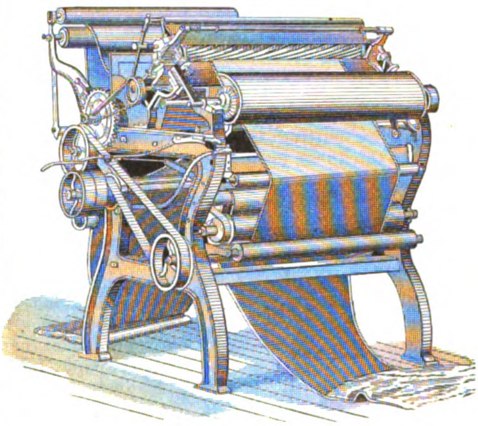
Shearing-Machine.

cutters; one of these is a continuous spiral cutting-edge upon the periphery of a roller, and the other a stationary blade; the nap is clipped between the two.

For removing the loose fibers from cotton cloth, it is passed over a hot plate or a row of gas-jets set closely together. See SINGEING-MACHINE.

Fig. 4924 is a view from another point of direction of a similar machine. It is intended for shearing brussels, axminster, tapestry, and ingrain carpets. The fabric is fed continuously through the machine, passing rollers which smooth it perfectly and pass it over a straight-edge. Here it is so sharply bent that the fibers are projected outward and caught between the spiral blades and a straight steel knife, between which the fluff is cut off or the pile reduced to a length, as the case may be.

Fig. 4924.



Shearing-Machine.

Fig. 4925 is a view of Curtis and Marble's mat-shearing machine. It has a revolving cylinder, with spiral knives cutting against a sharp straight knife known as a *ledger-blade.* It is constructed to cut five feet wide either in single mats or in strings.

The view shows a mat undergoing treatment.

Shearing-machines are made for shearing *crosscut, reversibly,* or *continuously.*

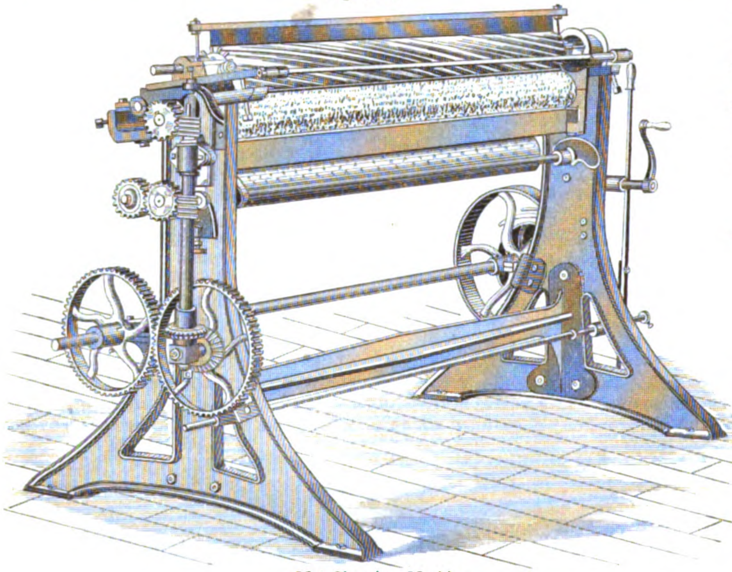
Shear′ing-ta′ble. (*Husbandry.*) A bench for holding sheep while being sheared. The table is tilted, the sheep backed upon it, and the table then restored to its horizontal position. The sheep is held by straps, and rests upon the curved block while under the operation of the shears. The spring-supporting rests sustain the leaves in the several positions they are made to assume in turning the sheep.

Shears. 1. A cutting instrument, operating like scissors, but on a larger scale and somewhat differently shaped. The edges of the blades are beveled, and the handles adapted for thumb and fingers respectively, instead of being duplicates. They are adapted for tailors' use.

Shears with two blades and a spring back were used in old Rome for clipping sheep, hair, and hedges.

Tinman's shears have relatively shorter jaws, and are either grasped in the hand or one leg placed in the vise while the other is worked by hand. They

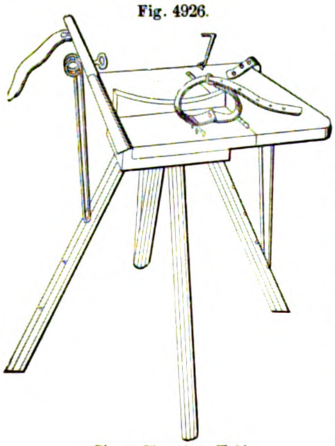
Fig. 4925.



Mat-Shearing Machine.

are used for cutting tin-plate and sheet-metal of moderate thickness, such as stove-pipe plate.

Fig. 4926.



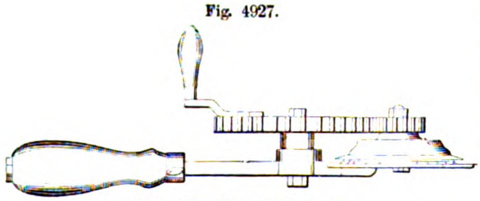
Sheep-Shearing Table.

Bench-shears have powerful blades with obtuse cutting-edges. The handles are made long in proportion to the blades, and the end of the lower one is bent downwardly at right angles, so that it may be inserted into a hole in the work-bench or table.

Hand-shears are used between the thumb and finger, in the same manner as cloth-shears, but have a stronger edge, being intended for cutting sheet-metal.

Fig. 4927 is a two-handed shears for clipping horses. One handle is for holding it to place, and

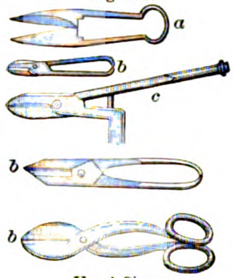
Fig. 4927.



Shears for Clipping Animals.

the other drives the circular cutter by means of a crank.

Fig. 4928.



Hand-Shears.

a, *sheep*-shears. See also SHEEP-SHEARS.

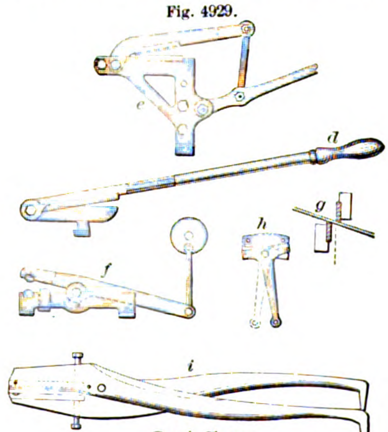
b, *hand*-shears or *snips*, used by sheet-metal workers.

c, *bench*-shears, used by tinmen and others. The blades are about one fifth of the total length, which is usually from 1½ to 4 feet; the square tang is to be inserted in a hole in the work-bench or a heavy wooden block. The handle is sometimes forged thicker at the end, to increase the cutting effect by its momentum when thrown down by a sudden jerk.

d, another form, in which the joint is at the extreme end, and the cutting-edge between it and the handle.

e, *purchase*-shears. These are worked by a lever united by a connecting-rod to the movable blade, and considerably increas-

Fig. 4929.



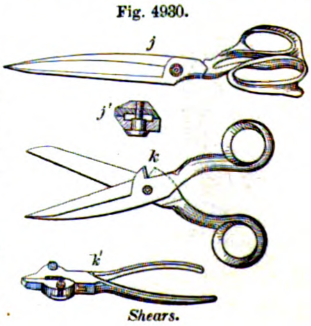
Bench-Shears.

ing the power; a spring is usually provided to press the two edges together, and a stop to determine the length or width of the pieces cut off. Were the edges of the blades not in contact, as seen at *g*, the effect would be to fold rather than cut the metal, and strain the shears.

f, *shears and squeezer*. The lower piece is firmly fixed; the cutting-edges are near the joint; and dies may be placed in the far end for swaging hot pieces of metal. The long arm of the cutting-lever is operated by a connecting-rod and eccentric driven by the engine.

h, *double* shears, used at the British Mint. The lower

Fig. 4930.



Shears.

piece has a cutter at each end, and acts by a rocking motion against the fixed upper piece.

i, bench-shears with a pivoted cutter, adjusted in each blade by means of a screw.

j. The blades are recessed at the pivot-hole *j'*, so that the metal, in cutting, is not compressed so much at that point, in order that it may remain soft after hammering, allowing the rivet-holes to be readily punched.

k. Two short, strong blades are formed on the sides of the large ones for cutting wire, whalebone, etc.

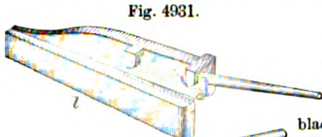
k'. Cutting-nippers having cutters which are held by screws, so as to be removable and replaceable, are also used for this purpose.

Shears are also made having a thin cutting-blade closing in between two opposite blades, which serve as guides for the cutting-blade.

Another description is provided with a series of removable cutters of different sizes, having triangular cutting-faces; these are secured in one jaw and cut into a suitable slot in the opposite jaw.

l. A stationary blade is fitted in the rabbeted face of the lower section, and a movable blade operated by a lever is hinged to the rabbeted face of the upper section; the faces of the sections give support to the blades.

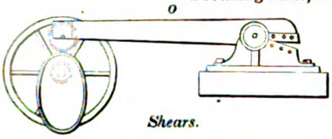
Fig. 4931.



m. For brush-makers. The wedge-shaped throat in the lower stationary blade holds the bristles while they are severed by the downward movement of the upper blade.

n. For cutting the bloom or mill bar as it comes from the roughing-rollers. The cutting-edges of hard steel are bolted to the lower stationary frame and to the upper movable jaw, which is operated by a connecting-rod from the fly-wheel shaft of the engine.

The bar-shears have usually one stationary and one oscillating jaw, and are used to cut bars of iron into pieces to be built into fagots for reheating and rerolling to form beams, nail-plates, or some peculiar grades of iron which owe their quality to repeated working. The moving jaw is operated by a cam on a rotating shaft, and makes its strokes in uniform time. See BAR-SHEAR, page 241.



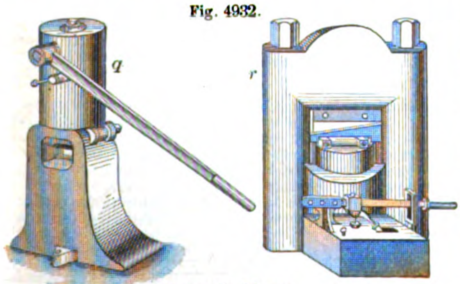
Shears.

o. Metal-shears. The cutters are attached and arranged as in the preceding case. The long lever of the upper jaw is operated by an eccentric on the fly-wheel shaft pressing against a roller pivoted in the end of the lever.

The machine for cutting to a length angle-iron for ships' frames consists of a fixed cutter in the form of a right-angled triangular notch, in which the angle-iron to be cut is laid with the angle downward; the movable cutter is a solid right-angled triangle, with the right angle pointing downward; it is fixed in the lower end of a block which slides between vertical guides, and has a reciprocating motion given to it by an eccentric on a rotating shaft, making twenty revolutions per minute or thereabout.

The effort required to shear a piece of iron is about 50,000 pounds per square inch of the area of the shorn surface. The work performed is about equal to that effort multiplied by half the thickness of the piece in the direction of shearing. For an equal area of steel, the effort is probably about double.

Fig. 4932.



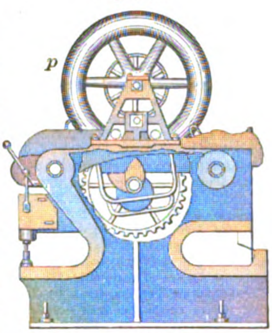
Hydraulic Shears.

The *shears* for cutting plates for the outside skin of a ship consist of a pair of straight cast-steel cutters: the lower one is fixed and horizontal; the upper or movable cutter has a slight slope to give it an oblique cut.

q r are forms of hydraulic shears. The movable cutter is attached to the ram of a hydraulic press, making in the former a downward and in the latter an upward stroke.

Fig. 4933, a combined shears and punch. The punch is connected with a lever making its effective stroke at one side of the machine, — the left in the illustration, — and operated by a yoke and a heart-cam: the movable shear-blade is attached to a lever making its stroke at the other side, and operated by a yoke and eccentric. The motions of both are derived from gear-connection with the fly-wheel *p*.

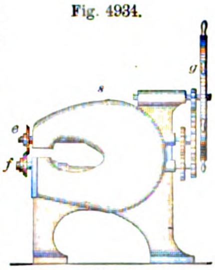
Fig. 4933.



Shears and Punch.

In Fig. 4934, the circular cutters *e f* are rotated in opposite directions by gears operated from the hand-wheel *g*. A number of these cutters may be arranged on each shaft, so as to cut a sheet of metal into a series of strips.

Fig. 4934.



Circular-Cutter Shears.

2. The *ways* or *track* of a lathe upon which the lathe-head, puppet-head, and rest are placed, and on which the latter is adjusted in the common lathe or slides in the traversing lathe.

3. For the hoisting device, see SHEERS.

See under the following heads: —

Bar-shears.	Hydraulic shears.
Bench-shears.	Lopping-shears.
Button-hole shears.	Pruning-shears.
Cattle-marking shears.	Punch and shears.
Clipping-shears.	Scissors.
Cutting-nippers.	Shear-grinding machine.
Edging-shears.	Shearing machine.
Garden-shears.	Shearing-table.
Grass-edging shears.	Sheep-shears.
Hair-clipping shears.	Sheet-metal shears.
Hand-shears.	Tailor's shears.
Hedging-shears.	Tinman's shears.

Shear-steel. Blister-steel, heated, rolled, and tilted to improve the quality.

Several bars are welded together and drawn out.

Shear-steel is named from its applicability to the manufacture of cutting instruments, shears, knives, scythes, etc.

The bar is sometimes cut, fagoted, reheated, and again tilted. This may be repeated. The terms *single shear* and *double shear* indicate the extent to which the process is carried.

Sheath. 1. A scabbard for a sword.

2. A case for a knife.

Sheath'ing. (*Shipbuilding.*) A covering, usually thin plates of copper or an alloy containing copper, to protect a wooden ship's bottom from worms. Lead was used for the purpose nearly as long ago as the Christian era.

The gradual oxidation of the copper has been prevented by the application of pieces of zinc or iron upon different parts of the surface. This renders the

copper electro-negative and preserves it, but at the expense of its cleanliness, as marine weeds and barnacles are more apt to adhere to it.

The order for the sheathing of the vessels of the English navy with copper-plate was given in 1783.

Sheathing-copper is laid on with a lap-joint, the lower and after edges of the sheet lapping upon the sheets below and abaft it. The grades are known by the number of ounces to the superficial foot, as 16-ounce, 18-ounce, 28-ounce, 32-ounce. The heaviest is put forward from the bows to the keel, and on the load-line and four strakes below it.

The sizes of these metallic sheets are as follows : —

Weight in ounces per square foot.....	18	28	32
Thickness in inches..................	0.025	0.038	0.044
Length in inches.....................	48	48	48
Breadth in inches....................	20	14	14

The thicker sheathing is used on the bows.

The sheets are put on in strakes, running fore and aft. The after end of each sheet overlaps the forward end of the next, and the lower edge of one strake overlaps the upper edge of the one below it.

Iron ships may be sheathed with copper or alloy by attaching to the iron skin a complete wooden surface to hold the sheathing-nails. This is, however, very expensive. See "Watts, Rankine, etc., Shipbuilding."

It has also been proposed to employ zinc, amalgamating its surface with mercury, so as to preserve it from the action of the sea-water; a galvanic current is thus established which prevents corrosion of the iron.

The ship of Trajan, sunk in the Lake of Nemi and recovered after many centuries had elapsed, was found by Alberti (sixteenth century) "to consist of pine and cypress in excellent preservation, which, besides a coating of black pitch, had a double covering of canvas glued on, and over it a sheathing of lead fastened with brass nails."

In 1613, a junk of 800 or 1,000 tons was seen by European navigators in Japan, entirely sheathed with iron. European vessels were first sheathed with copper in the seventeenth century.

In "Sir Richard Hawkins's Voyage to the South Sea," 1593, various kinds of sheathing to prevent the ravages of the teredo are mentioned. In Spain, very thin sheets of lead were used, but were not durable; canvas had been tried, but unsuccessfully. He recommends charring the outside of the planks and coating them with pitch or tar. In China a kind of varnish was employed. He also speaks of a compound of pitch and glass. His father had invented the best method then used in England; it consisted of two thicknesses of extra planking, between which was tar and hair in two layers. This was cheap and effective. The adhesion of barnacles and sea-weeds was a minor consideration.

Sheath'ing-met'al. The following are some of the alloys employed : —

Muntz's, copper, 60; zinc, 1.
Mushet's, copper, 100; zinc, ½.
Revere's, copper, 95; zinc, 5.
Wetherstedt's, copper, 90 to 97; antimony, 3 to 10.
Collins's (red), copper, 8; zinc, 1.
Collins's (yellow), copper, 10; zinc, 8.
Collins's (white), copper, 1; zinc, 16; tin, 16.
Pope's, lead, 1; zinc, 3; tin, 2.
Cast and roll into sheets at about 200°. See ALLOY.

Another alloy of Mushet's is composed of copper, 100 pounds; zinc, 0.5 ounce; tin, 0.5 ounce; antimony, 1 ounce; arsenic, 2. Or, the 100 pounds of copper may be alloyed with either one of the following: zinc, 2 ounces; antimony, 4 ounces; arsenic, 8 ounces; tin, 2 ounces.

Sheath'ing-nail. 1. (*Nautical.*) A cast nail of an alloy of copper and tin, used for nailing on the metallic sheathing of vessels. They are flat and polished on the head, countersunk beneath the head.

Weight of Composition Sheathing-Nails.

No.	L'gth.	No. in a Pound.	No.	L'gth.	No. in a Pound	No.	L'gth	No. in a Pound

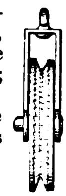
5	1¼	199						

2. (*Carpentry.*) A nail, in size 6*d.* to 8*d.*, used to nail on sheathing for shingling or slating.

Sheath'ing-pa'per. A large and coarse paper made for an inner lining of the metallic sheathing of vessels.

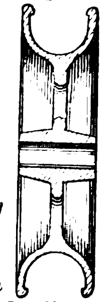
Sheave. 1. (*Hoisting.*) The grooved wheel in the *shell* of a block or pulley over which the rope runs. It is generally, in wooden blocks, of lignum-vitæ, and has a brass *bushing*, called a *coak*, which runs on the *pin*. See BLOCK; PULLEY; TACKLE, etc. A *Shiver*.

Fig. 4935.



Serrated Sheave.

Fig 4936.



Iron Sheave.

The pulley was known to the Greeks and Romans. Vitruvius describes the sheaves (*orbiculi*) in the blocks (*trochlea* or *rechamus*).

To increase the adhesion of the rope on the sheave, the latter may be serrated. This opposes the slipping of the rope. Fig. 4935.

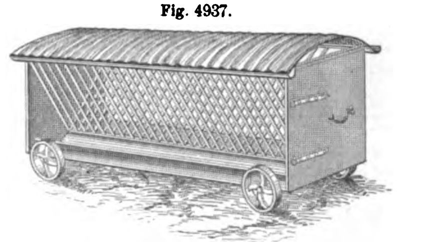
2. (*Locksmithing.*) A sliding *scutcheon* for covering a keyhole. See SCUTCHEON.

Shed. 1. (*Loom.*) The space between the upper and lower warps, forming a raceway for the shuttle.

2. (*Building.*) A lean-to frame building of one story.

Shed-roof. (*Building.*) A *lean-to*. Having but one inclined side.

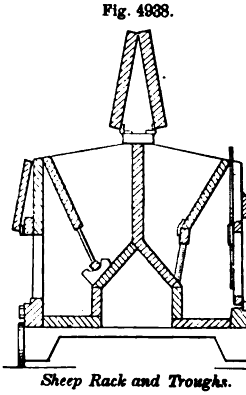
Fig. 4937.



Sheep-Rack.

Sheep-dip'ping Ap'pa-ra'tus. An English apparatus for dipping sheep, to enable their fleeces the better to protect them against the damp and changeable weather.

Fig. 4938.



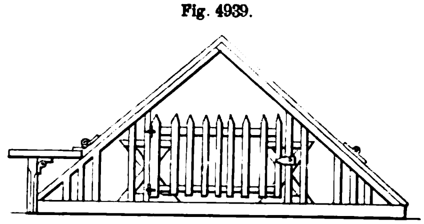
Sheep Rack and Troughs.

Sheep-hold'er. (*Husbandry.*) A cradle or table to hold a sheep while being shorn. Figs. 4942-4.

Sheep-hook. (*Husbandry.*) A shepherd's crook.

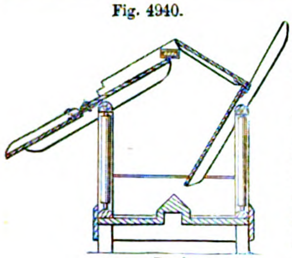
Sheep-rack. The portable wrought-iron sheep-rack (Fig. 4937) is mounted on four wheels, and has a wrought-iron hay-rack in the middle, a trough at each side, doors at the ends, and a corrugated iron roof with eave-gutters.

Fig. 4939.



Sheep Rack and Shed.

Fig. 4940.



Sheep-Rack.

Fig. 4938 is a double rack with lids, feed-troughs, and shutters.

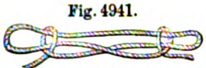
In Fig. 4939, the two feed-racks are placed in a shed whose hinged sectional roof is supported on angular end-framing and is convertible into an open shed.

In Fig. 4940, the doors are hinged and cleated to make a transferable open or covered rack for feed.

Sheep's-foot Trim'mer. A pair of shears or cutting-pinchers to trim the excessive growth of the hoof.

Sheep-shank. A peculiar mode of taking up the slack of a rope and shortening it temporarily. The rope is doubled in three parts, a hitch is taken over each bight with the standing part and jammed taut. See 42, Fig. 2777, page 1240.

Fig. 4941.

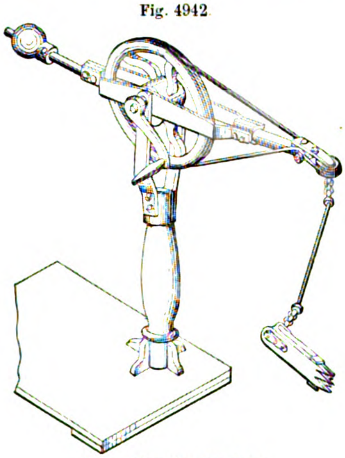


Sheep-Shank.

Sheep-shear'ing Ma-chine'. (*Husbandry.*) A machine for giving motion to the shears wherewith sheep are shorn. The shears are usually angular cutters reciprocated over guards, which act as the other halves of the shears, much as in the manner of mowing-machine cutters, but on a very small scale.

In Fig. 4942, which may stand as an example of a score of different machines of this class, the shears are at the end of a flexible shaft, which is rotated by band connection from the fly-wheel on the crank-shaft. The vibrating shears have a shield to prevent the wool being cut more than once, and are attached by a flexible connection and tumbling-rod to a counterbalance

Fig. 4942.



Sheep-Shearing Machine.

arm, which is pivoted upon a standard, in which is placed the driving-wheel which gives motion to the knife.

In another machine, a vibrating motion is communicated to the cutter while being moved in any direction or passed over the body of the sheep, so that two different persons may work with one machine at the same time and operate upon two different animals, while either cutter may be stopped independently of the other by simply releasing the lever which holds up its driving-shaft. The machine may be driven by horse, dog, steam, or water power.

See the following list of United States patents, which includes horse-clipping machines: —

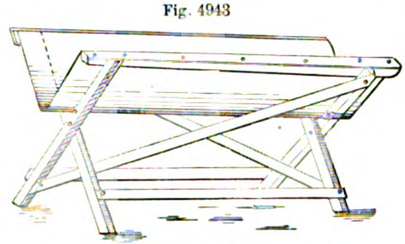
* Reissued.

Sheep-shear'ing Ta'ble. A holder or bench to hold a sheep while being sheared.

Fig. 4943 has a canvas bed supported on a double X-frame, and of sufficient capacity to hold the sheep.

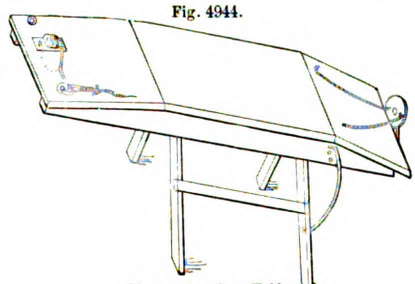
Fig. 4943



Sheep-Shearing Table.

In using Fig. 4944, the sheep being laid on the table, the cords attached to the rotating wheel fasten the hind legs. The curved spring hook holds its

Fig. 4944.



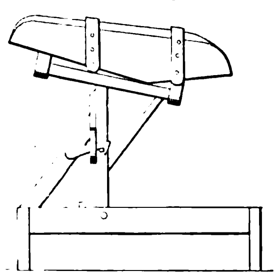
Sheep-Shearing Table.

neck, and the cord and snap secure the front legs to the eye-bolts on the table.

In Fig. 4945, the sheep is strapped in a trough, which is so pivoted as to give any presentation to the shearer, and to dump the animal when the operation is concluded.

Sheep-shears. The blades are united by a steel bow which makes them self-opening, the cutting being done by the grasp of the hand.

Fig. 4945.



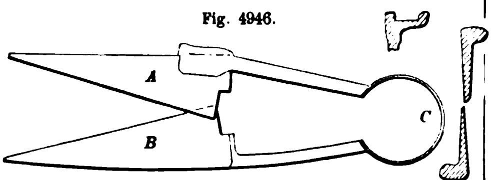
Sheep-Holder.

C, Fig. 4946, shows the bow, *A B* the blades; the example differs from the common sheep-shears in having a flanged projection at the heel of each blade, enabling the operator to take a firmer hold.

In Fig. 4947, the central blade affords cutting-edges to each of the side blades.

In Fig. 4948, the central blade is pivoted to one of the main blades, and its slotted shank is pivoted to an oscillating lever, which has its fulcrum on a

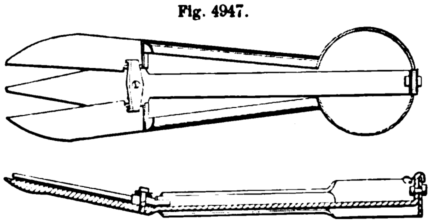
Fig. 4946.



Sheep-Shears.

stud from the side bar, and has a slotted connection to a pivot on the other main blade.

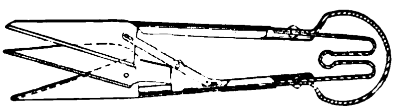
Fig. 4947.



Sheep-Shears.

In Fig. 4949, the teeth of the cutters are double-edged. The cutter-plates are connected by a screw

Fig. 4948.

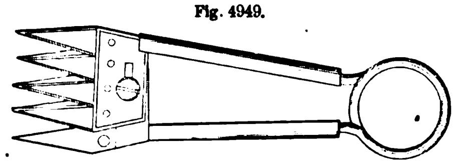


Three-Bladed Shears.

which is secured to one plate and traverses a slot in the other plate. The spring has one or more coils.

Fig. 4950 is a sheep-shears with a six-fingered comb and a revolving bladed disk. It is designed

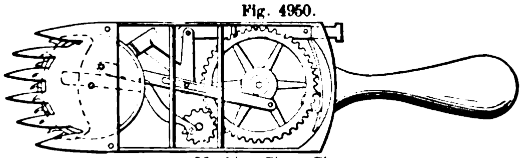
Fig. 4949.



Multiple-Bladed Shears.

to be used in a machine such as Fig. 4942. The shearing-comb is suspended from a crane by means

Fig. 4950.

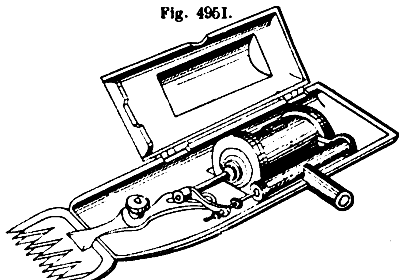


Machine Sheep-Shears.

of a flexible shaft, rotated by a hand wheel and belt, and descending in line with the axis of the main-wheel of the shearing-comb, to which it imparts motion and from which the cutters of the comb are actuated.

Fig. 4951 is a portable sheep-shearing instrument operated by air under pressure, the engine to operate the cutters being inclosed within the handle, and

Fig. 4951.



Sheep-Shearing Machine.

the compressed air being conducted thereto by a flexible pipe. The reciprocating cutter is oscillated by a lever.

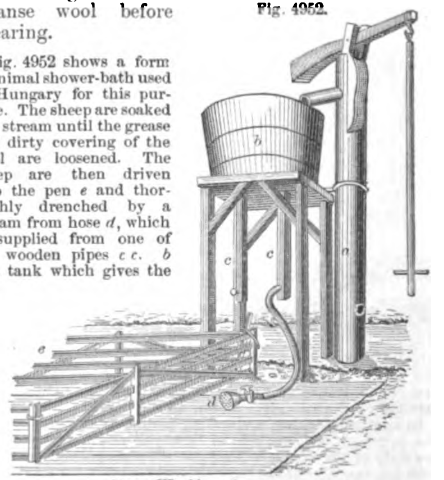
Sheep'skin. The tanned skin of a sheep, in demand for many of the commoner uses of leather, — shoe-binding, bookbinding, and wash-leather. In the latter case it is a substitute for chamois, and, indeed, is often tanned to represent goat and buck skins.

Sheep-split. The divided skin of a sheep. One half is a thin *skin* and the other a *split*.

Sheep-wash'ing Ap'pa-ra'tus. A mechanical arrangement to cleanse wool before shearing.

Fig. 4952 shows a form of animal shower-bath used in Hungary for this purpose. The sheep are soaked in a stream until the grease and dirty covering of the wool are loosened. The sheep are then driven into the pen *e* and thoroughly drenched by a stream from hose *d*, which is supplied from one of the wooden pipes *c c*. *b* is a tank which gives the necessary *head* to the flow of water. This tank is kept filled by pump *a*.

Fig. 4952.



Sheep-Washing Apparatus.

Sheer. 1. (*Shipbuilding.*) The upward curvature

of the lines of a vessel toward the bow and stern. Different views are entertained by different naval constructors as to the proper amount to be given. Sharp vessels generally have more than full-built ones; small vessels more than large ones; and merchantmen more than men-of-war.

When the deck is perfectly flush from stem to stern, a vessel is said to have a straight sheer.

2. (*Nautical.*) The position of a ship riding at single anchor with the anchor ahead. When riding at short scope of cable, when she swings at right angles to the cable, exposing a larger surface to the wind or current, and causing the anchor to drag, she is said to *break her sheer.*

The only natural boat occurring to the writer, made specifically for the purpose, is that built of eggs by the gnat. It consists of, say, from 250 to 350 eggs; is sharp, high fore and aft, convex below, concave above, and floats uniformly keel down. It has a natural sheer, and though it pitches and rolls in its mimic ocean, is trim and lively and never founders. To say that it is never wrecked would be too much.

"The best-laid schemes o' [gnats] and men
Gang aft a-gley."

Sheer-bat'ten. 1. (*Shipbuilding.*) A strip nailed to the ribs to indicate the position of the wales or bends preparatory to those planks being bolted on.

2. (*Nautical.*) A horizontal batten seized to the shrouds above the dead-eyes to keep the latter from turning.

Sheer-boom. (*Lumbering.*) A boom in a stream to catch logs and direct them toward a log-pond. One end is moored to the shore, and it has rudders set at such an angle as to catch the force of the current obliquely, and thus maintain its position at a certain angle across the direction of the stream.

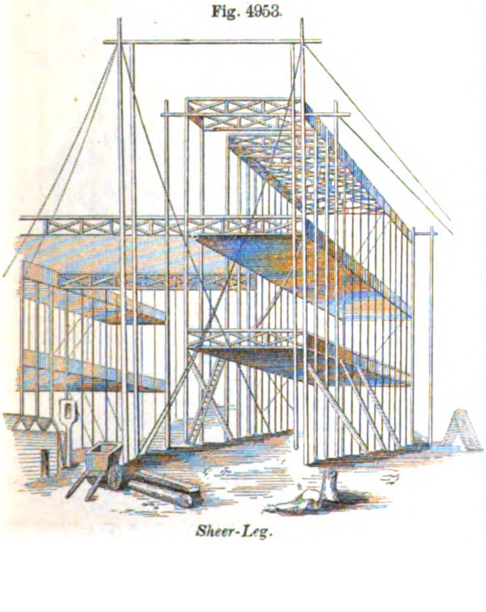
Sheer-draft. (*Shipwrighting.*) The plan of elevation of a ship whereon is described the outboard works, as the wales, shear-rails, ports, drifts, heads, quarters, post, and stem, etc., the hang of each deck inside, the water-lines, etc. (MEADE.) The *sheer-plan.*

Sheer-hulk. (*Nautical.*) An old vessel fitted with sheers for taking out and putting in masts of vessels. See SHEERS.

Sheer'ing. Deviating to either side of the line of the course.

Sheer-lash'ing. (*Nautical.*) The mode of lashing together the legs of the sheer at the cross. The middle of the rope is passed around the cross, the ends passed up and down respectively, then returned on their own parts and lashed together.

Fig. 4953.



Sheer-Leg.

Sheer-leg. (*Hoisting.*) Sheer-legs were employed in lieu of scaffolding in the erection of the Crystal Palace building at Sydenham, 1851. Two poles were placed upright and connected at top by a cross piece; the whole being steadied by guys. The columns were hoisted into a vertical position by a rope and pulley, and held until they were bolted to their bases. When two columns had been fixed in position, a connecting piece was attached to each end of the girder, which was raised by the same means and bolted on to the tops of the columns.

Sheer-line. 1. (*Shipbuilding.*) The line of the deck at the side of the ship.

2. (*Military.*) The stretched hawser of a flying bridge along which the boat passes.

Sheer-mast. (*Nautical.*) One formed of a pair of spars, between which the yard of the sail is slung.

Sheer-plan. (*Shipbuilding.*) A vertical, longitudinal, 'midship section of a vessel, on which are projected various lines which, in an architectural drawing, would be shown by an elevation, as, —

Water lines (blue).	Main-breadth line.
Level lines.	Top-breadth or top-timber line.
Diagonal lines (red).	Top-side line.
Buttock and bow lines.	Cutting-down line.

Sheer-rail; Waist-rail. (*Shipwrighting.*) A rail surrounding a ship on the outside, under the gunwale.

Sheers. 1. (*Nautical.*) Originally spelt *shears,* from the resemblance, in form, to cutting shears. Bailey, 1725; Phillips' "World of Words," 1658. Modern maritime custom has otherwise determined it.

An apparatus consisting of two masts, or *legs,* secured together at the top, and provided with ropes or chains and pulleys; used principally for masting or dismantling ships, hoisting in and taking out boilers, etc.

This kind of hoisting-machine has two legs. The *derrick* has one; the *gin,* three. The two former require guys; the latter stands independently.

The legs are separated at their feet to form an extended base, and are lashed together at their upper ends, to which the guy-ropes and tackle are attached. The sheers has one motion on its steps describing an arc, and is inclined from the perpendicular to a greater or less extent as required, by slacking or hauling on the guy-rope or fall of the sheer-tackle.

Temporary sheers are made of two spars lashed together at top and sustained by guys.

Permanent sheers are sloped together at top and crowned with an iron cap bolted thereto. It is now usually mounted on a wharf, but was formerly placed on an old hull called a *shear-hulk.*

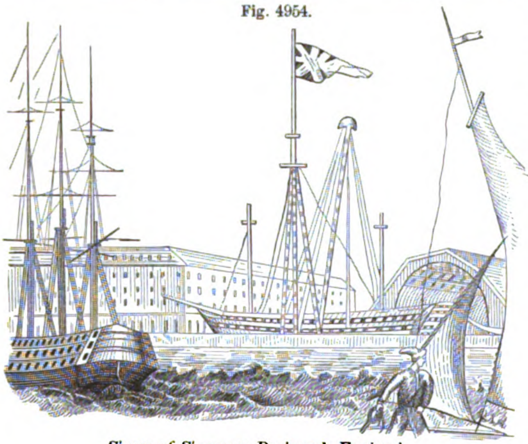
The sheers of Sheerness Dockyard, England (Fig. 4954), are 127 feet long, with an average diameter of 37 inches, and framed like a lower mast of a first-rate.

In Fig. 4955, *A* represents Wylie's sheers. *a a* shows the sheers overhanging a vessel *b b,* in position for raising or lowering an object on the wharf. *c,* the two engines. *d,* a long screw for working the sheers. *e,* hoisting-winch with wormed barrel. *f f,* purchase-blocks.

B, the sheers at Woolwich Dockyard, end and side elevation. The spars *b c* and central mast *a* are *made,* the pieces being joined by dowel-pins and iron plates. They are connected with each other by straps *d* and with the mast by braces *e,* and the spars *c* are swiveled on a collar at the foot of the central mast.

A similar contrivance is used in mining and for suspending the tackle used in mounting and dismounting guns.

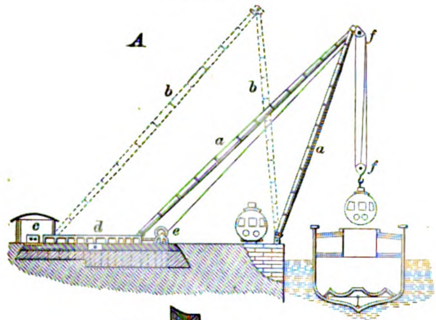
Fig. 4954.

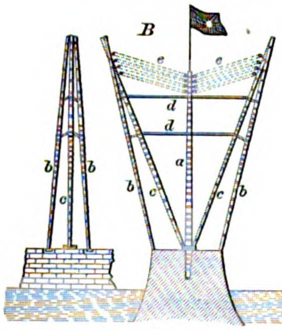


Sheers of Sheerness Dockyard, England.

Sheer-strake. (*Shipbuilding.*) The strake under the gunwale in the top side. It is generally worked thicker than the rest of the top sides, and is scarfed between the drifts.

Fig. 4955.





Sheers.

Sheet. 1. (*Nautical.*) A rope attached to the clew of a sail, in order to extend it. Lower square sails, or courses, have another rope, the *tack*, attached to each clew, serving to haul forward and secure the weather corner of the sail, while the lee corner is hauled aft by the sheet. Upper sails have sheets only.

Fig. 4956.

Sheet-Bend.

2. A thin plate of metal or glass.

3. A broad piece of paper. The same printed.

Sheet-an′chor. (*Nautical.*) The largest anchor of a ship. Others are known as *bower*, *stream*, *kedge*, etc. See ANCHOR.

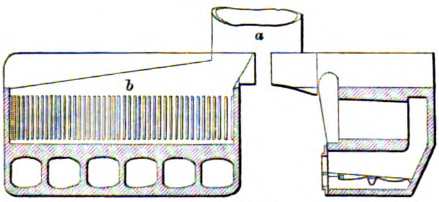
Sheet-bend. (*Nautical.*) *a.* A double hitch formed by laying the bight of one rope over that of another, passing its two parts under the two parts of the other and upward through its bight crosswise and overlaying it.

b. The strongest cable on board ship; bent to the sheet-anchor.

Sheet-flue Boil′er. A marine steam-boiler in which the flues are formed of flat sheets instead of cylindrical pipes.

Lamb and Summers, English patent. The cut illustrates the boilers of the English troop-ship "Himalaya." *a*, chimney; *b*, flues, 48 in number, 6′ 5″ long, 3′ 9″, $1\frac{5}{8}$″ wide; water-spaces, $2\frac{5}{8}$″.

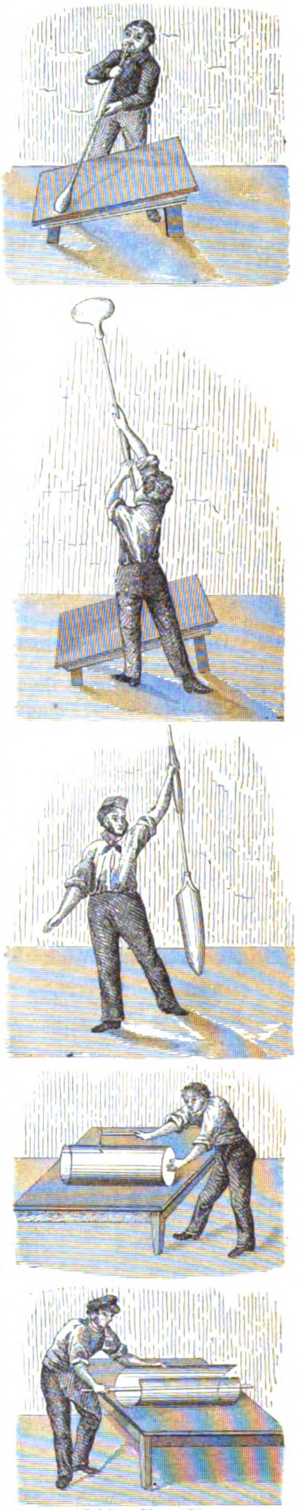
Fig. 4957.



Sheet-Flue Boiler.

Sheet-glass. In the Continental method of making sheet-glass, — introduced into England in 1850 by Chance Brothers, Birmingham, on the occasion of the construction of the World's Fair Expo-

Fig. 4958.



Making Sheet-Glass.

sition building by Sir Joseph Paxton,—the workman takes up a quantity, some 12 or 14 pounds of the semi-fluid material from the melting-pot upon the end of his tube, and elongates it by rolling upon a wooden table; he then blows it into an elongated spheroidal form, and then swings it around in a vertical circle, reheating it two or three times, until the end not attached flies open and the glass assumes the form of a hollow cylinder. The cylinders are cut longitudinally with a diamond, and placed in a furnace, where they open out into sheets under the influence of heat. Glass made in this way is also known as *cylinder*, *broad*, *spread*, *German* glass. (See CYLINDER-GLASS.) The composition is the same as *crown*-glass.

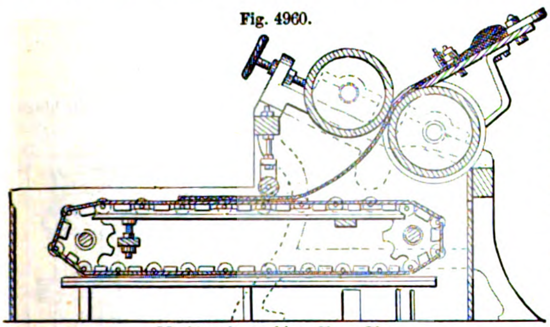
Fig. 4959.

Flattening the Sheet.

Figs. 4958, 4959, show the various operations and the conditions of the glass in the various stages.

Sheet-glass Ma-chine′. A machine for rolling hot plastic glass into a sheet. The melted glass is poured on to a table on which are side-pieces to regulate the opening through which it passes, and, consequently, the width of the layer. From the inclined table it passes between the rollers, whose distance apart regulates the thickness of the sheet. The platform is made of hinged plates with slides, and is inclosed by a casing, which has openings with slides to regulate its temperature, and also an adjustable roller to press the glass upon it and straighten any bend.

Fig. 4960.



Machine for making Sheet-Glass.

The Messrs. Chance, of Birmingham, are understood to have spent about £100,000 in attempts to manufacture heavy plate glass by similar means. See page 982. See also Bessemer's English patent, 1849.

Sheet′ing. 1. (*Fabric.*) Common muslins, bleached or unbleached. Sometimes made of double width, for sheets.

2. (*Hydraulic Engineering.*) A lining of timber or metal, for protection of a river-bank. Timber is the usual material, and consists of *sheet-piles* or of *guide-piles* and planking, fortified by anchoring to the bank in the rear.

3. (*Tobacco.*) Laying the leaves flat to be piled in *books*. See TOBACCO-SHEETING MACHINE.

4. (*Wool-manufacture.*) A form of batting. See next article.

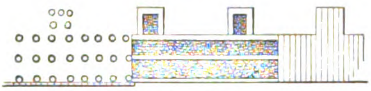
Sheet′ing-ma-chine′. 1. (*Wool-manufacture.*) A wool-combing machine for bringing the fiber into an even sheet. The surface of a drum is provided with long comb teeth, like porcupine quills, and hence called a *porcupine roller*. The *sheeter*, having gathered a bat, is denuded by stripping off the envelope of wool, which is then ready for *combing*. Ross's English patent, 1851.

2. (*Tobacco.*) A machine for smoothing tobacco-leaves. See TOBACCO-SHEETING MACHINE.

Sheet′ing-pile. (*Hydraulic Engineering.*) A plank, tongued and grooved, driven between two principal piles, to shut out the water.

The exterior piles of a coffer-dam or other structure, serving to sustain a filling in of earth, masonry, or other material.

Fig. 4961.



Sheeting-Piles.

Sheet-ir′on. In the British Exhibition of 1851, the American department exhibited some specimens of extremely thin sheet-iron. The friendly competition which resulted is worthy of notice.

Gillott, the celebrated steel-pen maker (deceased, December, 1871), rolled sheets the $\frac{1}{1800}$ part of an inch in thickness. These iron sheets were smooth and easy to write upon, though porous when held up to the light. Fine tissue-paper is about the $\frac{1}{1200}$ part of an inch in thickness; and the famous Pittsburg letter written on iron, which gave rise to the competition, was a sheet $\frac{1}{1000}$ of an inch. The dimensions were, $8 \times 5\frac{1}{2}$ inches $= 44$ square inches area, the weight 69 grains.

The Marshfield Iron-Works, of Caermarthenshire, Wales, made a sheet of the same dimensions, weighing only 46 grains.

The Hope Iron-Works, Staffordshire, England, made a sheet of 119 square inches area, weighing 89 grains, which, reduced to the former standard of 44 inches area, is equal to 33 grains.

The Marshfield tries again, and reduces it to $23\frac{1}{2}$ grains; a thickness of 2,583 sheets to the inch.

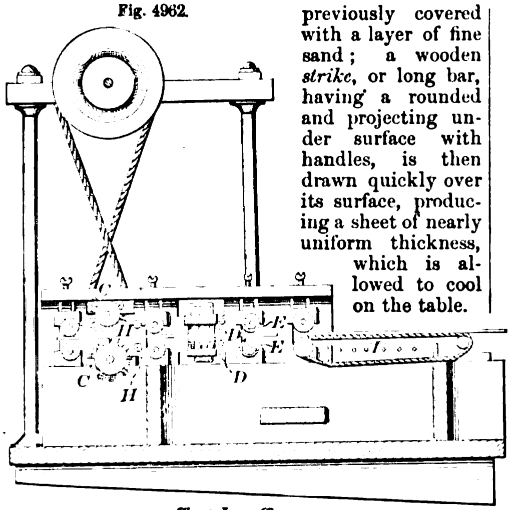
The Upper Forest Tin-Works, of Swansea, now wear the palm, having produced a sheet $10 \times 5\frac{1}{2} = 55$ inches area, weighing but 20 grains, equal to 16 grains for an area of 44 inches, and having a thickness of $\frac{1}{4800}$ of an inch. See also RUSSIA IRON.

Sheet-ir′on Gage. See SHEET-METAL GAGE.

Sheet-ir′on Clean′er. An apparatus for cleansing the surfaces of iron sheets after rolling. It consists of a series of feed-rollers, which pass the sheet between a series of revolving brushes *C C*, and another pair of flat brushes *D D*, which have a reciprocating motion across the top and bottom surfaces of the sheet, upon which, meanwhile, jets of water are forced through small tubes *H H* for that purpose. The sheet then passes between two elastic squeezing-rollers *E E*, which deprive it of a great proportion of the moisture, and is then passed over a furnace *I*, which completes the drying process and prevents oxidation.

Sheet-lead. The old process of making sheet-lead is by pouring the molten metal upon a table having raised ledges at each side, its top having been

Fig. 4962.



Sheet-Iron Cleaner.

previously covered with a layer of fine sand; a wooden *strike*, or long bar, having a rounded and projecting under surface with handles, is then drawn quickly over its surface, producing a sheet of nearly uniform thickness, which is allowed to cool on the table.

When prepared by milling or rolling, a plate of the metal some six or seven feet square and six inches thick is cast in an iron frame. This is hoisted upon the rolling milling-machine, which consists of a long frame provided with a number of wooden rollers, over which the plate is drawn, and having midway of its length two heavy metallic laminating-rollers, between which the plate is drawn a sufficient number of times to reduce it to the required thickness, the distance between the rollers being successively reduced previous to each operation.

For thin sheet-lead this may have to be repeated several hundred times. When the sheet has grown too long for the table, it is cut in two and each part milled separately.

When finished, it is cut into lengths which are formed into rolls. The thickness is indicated by the number of pounds which a square foot weighs.

By another plan, the metal is formed into thin pipes, which are opened longitudinally and flattened out. In making pipe, the lead is forced through an annular space between a core and an inclosing pipe. Hydraulic power is used.

Weight of Lead per Square Foot.

Thickness.	Weight.	Thickness.	Weight.	Thickness.	Weight.

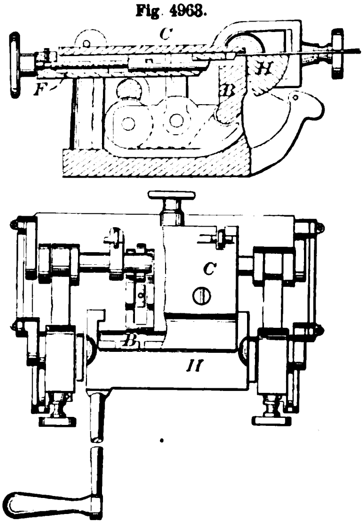
Sheet-met'al Bend'ing-ma-chine'. One for forming plates into shape between dies or rollers.

The folding-bar *H* is secured to shafts which rotate in adjustable bearings on bars attached to a cam-shaft. When the folding-bar is rotated, the cams cause the folding-knife *C* to hold the metal while being bent, and the folding-bar is prevented from being raised too high by slotted straps. A gage, adjustable by a screw *F*, is arranged beneath the folding-blade to regulate the width of the lock.

The distance between the folding-bar and the bed-piece *B* is adjustable by a screw to determine the suddenness of the bend at the angle. Fig. 4963.

In Fig. 4964, the frame *A* is adapted to receive counterpart dies *K G* of various curves, which are brought together by the movement of a lever, shaping the sheet of metal between them. The flat die *O*, also removable, is used in forming some descriptions of eaves-troughs.

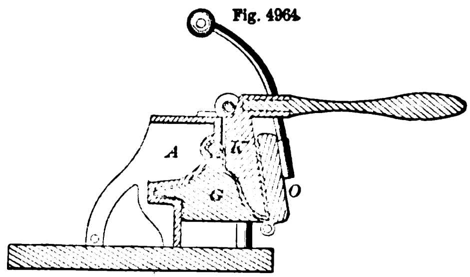
Fig. 4963.



Sheet-Metal Bending-Machine.

Fig 4965 is a machine for forming rectangular pans. The

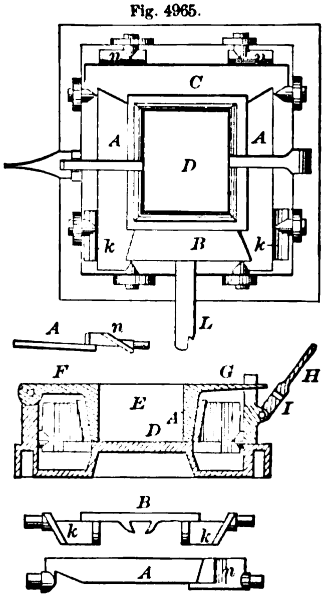
Fig. 4964.



Sheet-Metal Bending-Machine.

sheet of metal is placed on the block *D*, and held by the hinged interior forming die-clamp *F E G*, secured by throwing up the lever *H*, so that its slot *I* engages the arm *G*. The side-forming plates *A A B C* have cam-faces *k k n n* corresponding with each other in each plate, so that, on turning up the plate *B* by means of the lever *L*, they are caused to close in simultaneously upon the sides of the die-clamp *F E G*, bending the sheet-metal to the required shape.

Fig. 4965.

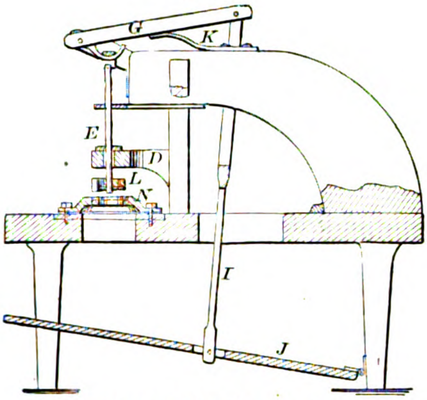


Machine for forming Bread-Pans.

Sheet-met'al Die. A former, one of a pair, between which sheet-metal is struck.

The machine (Fig. 4966) is especially designed for cutting out

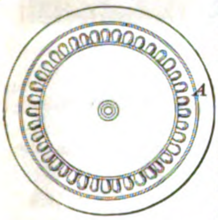
Fig. 4966.



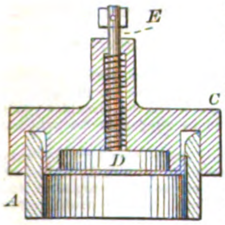
Tinner's Sheet-Metal Forming-Machine.

flaring work, such as the sides of pans, pails, and basins. The dies L N are adjustable to suit the size of the work. The knives are made in sections, so as to be readily detached for sharpening. The upper die L is fixed to the rod E, passing through the curved guide D, and brought down by the lever G, operated through the pitman I and treadle J; a spring K throws the die up again after each depression.

Fig. 4967.



In Fig. 4967, the upper inner edge of the hollow die A has flutings or serrations whereby the tin or other metal to be struck up is crimped evenly to prevent the uneven lapping and consequent breaking of the metal. A plunger D, within the upper die C, operated by a spiral spring, serves to free that die from the lower one after a stroke is made.



Die and Plunger.

Sheet-met′al Draw′-ing-press. A machine for stamping out seamless articles from sheet-metals.

It consists of an upright frame with a vertically reciprocating cross-head a carrying a blank holder b containing a reciprocating plunger. The blank holder and plunger are independently operated by cams on shafts driven by a worm and wheel. By the action of the plunger the blank is forced into the die c, which imparts the desired shape.

The blank holder is adjustable to adapt the press for drawing different thicknesses of metal.

Sheet-met′al Fold′er. See SHEET-METAL BENDER; SHEET-METAL FORMER; SEAMING-MACHINE.

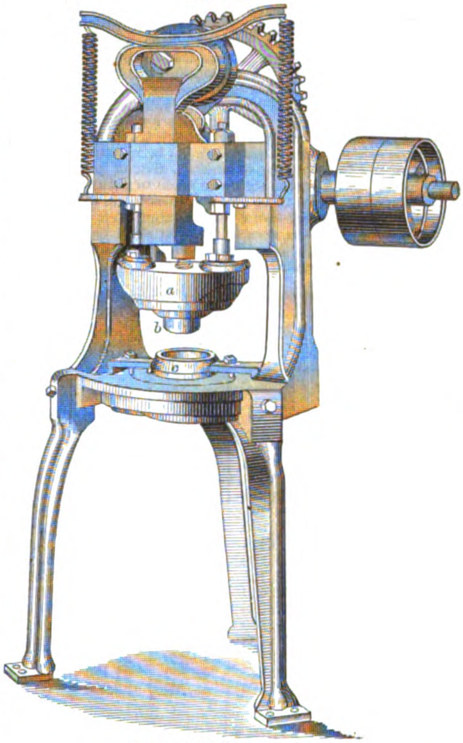
Sheet-met′al Form′ing-ma-chine′. A machine for bending sheet-metal into form.

In Fig. 4969, the upper die H is hinged to the lower die E, is lifted to place a sheet of metal in place for stamping, and then thrown over and the arm G secured by a catch. The central part F of the lower die has hinged side and end formers g, which, when the two dies are drawn downward, descend between guides C D, which throw up the formers g, and bend the metal to the required shape against the upper die H. Square pans are thus produced

Sheet-met′al Gage. A measure for thickness of sheet-metal.

The pocket-gage (A, Fig. 4970) consists of a V-shaped piece a provided with an adjusting-screw c and a gage-screw d; the latter passes through a collar b and is attached to a thimble e

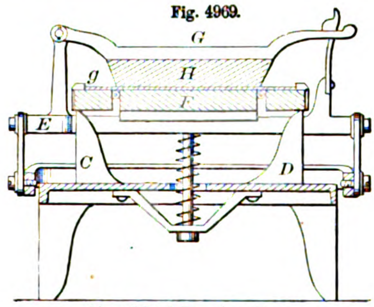
Fig 4968.



Sheet-Metal Drawing-Press.

surrounding the collar. The collar is graduated to fortieths of an inch, the distance by which the screw is moved at each turn,

Fig. 4969.

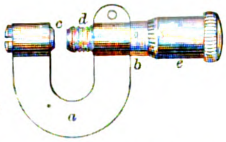


Sheet-Metal Forming-Press.

and the beveled edge of the thimble is circularly divided into twenty-five parts. The number of complete turns of the screw

Fig. 4970.

A



B

Sheet-Metal Gages.

d indicated on the collar b + the distance it has advanced in another partial revolution shown by the graduations on the thimble gives the distance between the abutting ends of the two screws c d, and consequently the thickness of a sheet of metal

or wire which can just be inserted between them, in thousandths of an inch. Thus, if the screw has made four and a fourth revolutions, four divisions on the collar *c*, each equivalent to twenty-five thousandths of an inch, will have been passed over by the thimble, and the mark five on the thimble will coincide with the longitudinal line on the collar, showing that the gage is open to one hundred and five thousandths of an inch.

B, Fig. 4970, consists of a stand *a* with a slotted upright having an adjusting-screw *c* above, and a screw *d*, with a milled head and carrying a dial, passing through its lower part. One turn of the screw, whose threads are 1/10 inch apart, causes one rotation of the dial, the edge of which is divided in one hundred parts, enabling measurements to be made to thousandths of an inch. The sheet-metal to be gaged is inserted in the slot of the upright. The adjusting-screw is set so that when the points of the two screws meet, the zero of the dial shall be opposite an index or pointer which shows the number of divisions passed over, and is firmly secured by a set-screw.

Weight of one Square Foot of various Metals.

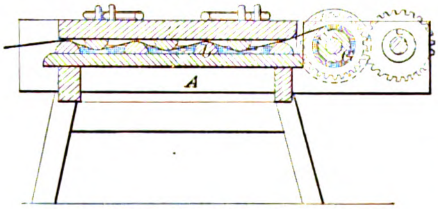
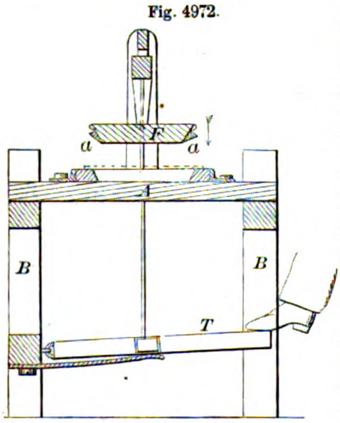
Sheet-met′al Pol′ish-er. One for clearing the surface of scale or stain before tinning, painting, etc.

Fig. 4971.



Sheet-Metal Polishing-Machine.

Fig. 4972.



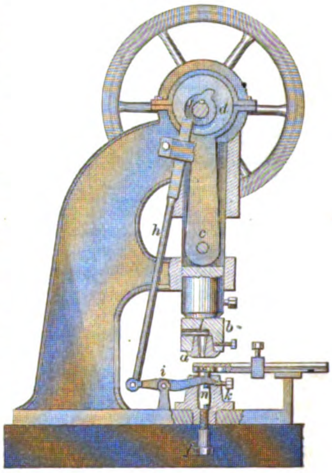
Sheet-Metal Press.

The sheets of metal are drawn through a trough *A* and presser *b* having corrugated surfaces, and are wound upon a removable spindle *G*. The sheets of metal are passed through a trough, having pressure applied to corrugated scouring surfaces, between which the metal passes to a removable sleeve on a revolving shaft.

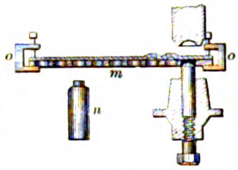
Sheet-met′al Press. A machine for forming articles of sheet-metal by pressure.

That illustrated consists of a table having two uprights *B B*, the upper ends of which are united by a bar *A*; said uprights form the guides for a beam which carries the punch *F*, and to which a rising and falling motion is imparted by a treadle *T*. The punch is secured to the beam by means of a stem, the lower end of which fits in a socket in the punch. The punch is made to correspond to the shape of the pans to be produced, and from its corners project wings *a a* which, when the punch is depressed, fit into corresponding slots in the corners of a die; this die is constructed of a series of sections which are made wedge-shaped, and is held in position by adjustable brackets.

Fig. 4973.



Sheet-met′al Punch. A machine for perforating sheet-metal.



Seifurth's Punching-Machine.

In Seifurth's punching-machine the die *a*, fixed in the block *b* by a screw, is caused to reciprocate by means of a pitman *c* and eccentric *d*. The punch *n* is stationary and adjustable in hight by a screw *f* beneath. The cam *g* and rod *h* operate the lifter *i*, which has two prongs, one on each side of the punch-holder *k*; these rise after the blow is given, and immediately fall back, allowing the workman time to adjust the sheet of metal before the die returns; the die and block have openings *l* through which the punchings escape.

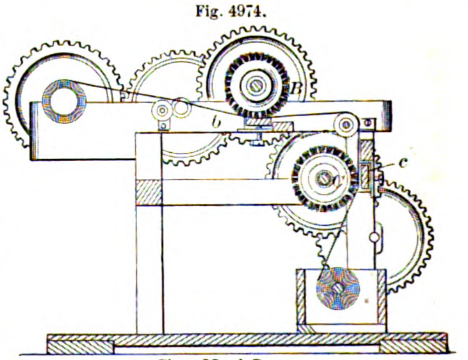
A gage *m*, secured by clamps *o* to the sheet, serves to guide the punch; the holes in these are larger than the diameter of the face of the punch *n*, which has a convex shoulder; this arrangement permits holes of various shapes to be punched without using special gages.

By employing different gages any description of holes may also be punched without the necessity of previously laying off and marking their positions. By varying the hight of the punch, impressions of any desired depth may be made in the metal. See also PUNCH.

Sheet-met′al Scour′er. A machine for cleaning sheet-brass and other metal after annealing.

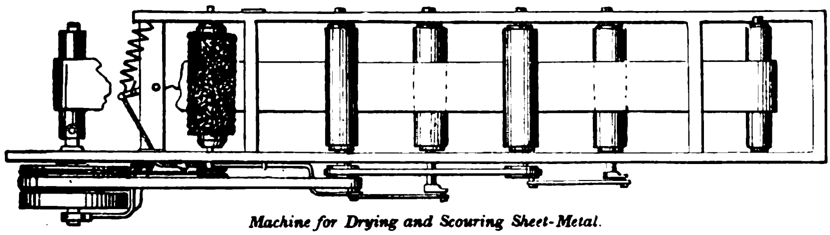
The metal being drawn through the machine is held against the wire brushes *B C* by the riders *b c*, and it is thus scoured and polished. See also Figs. 4962, 4971.

Fig. 4974.

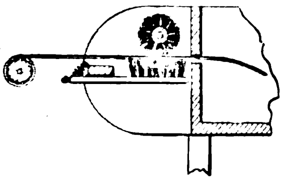


Sheet-Metal Scourer.

Fig. 4975.



Machine for Drying and Scouring Sheet-Metal.



A series of rollers covered with an elastic or fibrous material for holding sand, is so arranged as to pass the sheet-metal alternately above and below a roller. A vibrating motion is given to two of the under rollers by connecting-rods attached to crank-pins peculiarly arranged on pulleys. A pivoted brush is made to reciprocate across the under surface of the sheet-metal.

Sheet-met'al Shears. (*Tinman's Tools.*) A shears having one leg bent for insertion into a work-bench or table to which it is fixed. See SHEARS.

Sheet-met'al Straight'en-er. The sheet is subjected to gradually diminishing bends between rollers or surfaces that act crosswise of the bends or buckle of the plate.

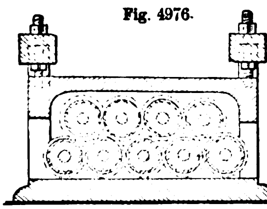
Sheet-met'al Work'er's Tools. See PLUMBER'S AND SHEET-METAL WORKER'S TOOLS.

Sheet-pile. A closing pile; one of thick plank driven between the main piles of a work to close the aperture. A *sheeting* pile.

Shelf. (*Building.*) A ledge for holding articles, secured to a wall, etc.

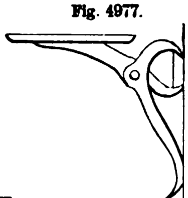
A removable shelf (Fig. 4977) has a bracket with

Fig. 4976.



Machine for straightening Sheet-Metal.

Fig. 4977.



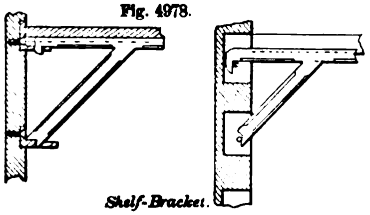
Shelf.

pivoted arms, whose jaws embrace a cleat which supports it; one of the arms resting against the wall serves as a brace. The claws of the bracket are pivoted together, the ends of the lower being turned up for the attachment of the shelf, and that of the other turned down for a brace.

2. (*Shipbuilding.*) An inner timber following the sheer of the vessel and bolted to the inner side of the ribs to strengthen the frame and sustain the deck-beams. See BEAM; SPIRKETING.

Shelf-brack'et. A device for supporting a shelf. In the example, the inner end of the horizontal bar of the bracket has a hook-catch, and the lower end of the brace has a notch, which respectively take over or bear against the bars of the vertical series which are placed in the back of the case.

Fig. 4978.



Shelf-Bracket.

Shell. 1. (*Ordnance.*) A hollow projectile containing a bursting-charge, which is exploded by a time or percussion fuse. (See CANNON; PROJECTILES; FUSE.) Invented at Venlo, 1495; used by the Turks at the siege of Rhodes, 1522.

Bomb-vessels were constructed in France, 1681.

Shells are usually made of cast-iron, and for mortars and smooth-bore cannon are spherical; but for rifled guns, they are, with the exception of Whitworth's and a few others, cylindrical and have a conoidal point. They are caused to take the grooves in a rifled gun, to receive a rotary motion, by means of a disk or ring, the *sabot*, which is expanded in act of firing, or by studs on the body of the shell. Those on the Whitworth principle are polygonal in section, corresponding to the bore of the gun, which they accurately fit.

Round shells for guns are made thicker than those for mortars, and have a reinforce at the fuse-hole; in mortar shells this is dispensed with.

The application of the rifled principle and elongated projectiles to cannon attracted little attention until the Franco-Italian war of 1859, where their efficacy was fully demonstrated.

Among the earliest American improvers in this line were James and Read, but no great practical results were achieved until after the beginning of the late civil war, when the talent of a host of inventors was concentrated upon it, resulting in bringing both projectiles and cannon into a very efficient state within a year or so after the beginning of the contest.

Ordnance shells have been constructed in great variety, some depending upon the force of the charge to burst the shell into fragments of indefinite size; others having lines of easy fracture indented in them; others built up of pieces, which become separated when the charge explodes, as the Armstrong; others full of bullets, as the shrapnell.

Among the more prominent American inventions are, —

Sawyer's, 1855 (*a*). This has a layer of soft metal with flanges outside the inner iron shell, which is forced forward by the shock of firing so as to fill the bore, while the flanges take the grooves.

Read, 1856 (*b*). Has a wrought-iron cup imbedded in a groove at the base of the shell.

Major Laidley, 1857 (*c*). A metallic jacket surrounds the cylindrical part of the shell, and is attached by being imbedded in a groove or by dowels. Sufficient space is left between the two for the entrance of gas.

Hubbell, 1860 (*d*). A circumferential recess in the shell receives a leaden band, which includes a wire coil, and has circumferential grooves to prevent stripping. The whole is covered with canvas.

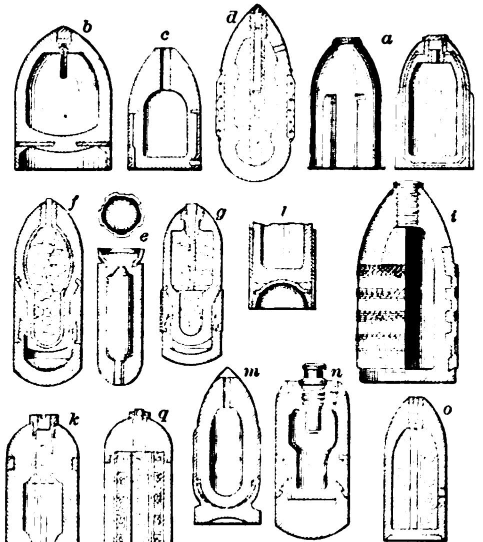
Parrott, 1861 (*e*). A cup of brass or iron is let into the base of the shell, and swaged so as to nearly correspond to the grooves and *lands* of the gun, leaving a very small windage, which is entirely overcome by the expansion of the cup on firing.

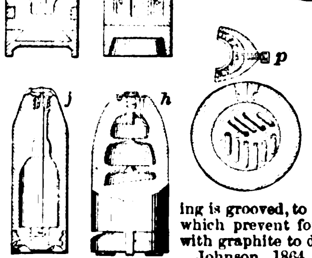
Hotchkiss, 1862 (*f*). The shell is made in two parts, the front one being thinned at the rear and surrounded by a soft metal ring, which is expanded at the moment of firing by an annular wedge at front of the rear part. When filled with leaden balls, it is termed a bullet-shell. A later form (*g*) contains a charge of powder, separated from the balls by a plate, and ignited by the fuse, so as to give them an additional impulse at the moment of bursting.

Another improvement consists in making longitudinal grooves in the shell, to insure the passage of flame to the fuse at the moment of firing. A disk of soft metal may also be interposed between the base and front sections to moderate the shock when the two are impacted, and lessen the danger of fracture.

h. At a later period, the powder-chamber was divided into several communicating compartments, to avoid the danger of the bursting-charge becoming ignited by friction against the sides and exploding within the gun,—an event which sometimes happens. Varnishing the interior also lessens danger from this source.

Fig. 4979.





Shells.

Broadwell, 1866 (*i*). The soft metal packing is grooved, to receive bands of cord, which prevent fouling, and are coated with graphite to diminish friction.

Johnson, 1864 (*j*). The shell has a charging-hole closed by a screw-plug at its base. A rod armed with a percussion-cap extends longitudinally through the powder-chamber, and the cap is exploded by an anvil, which is detached from the breech-plug and thrown forward when the shell strikes.

Absterdam, 1864 (*k*), employs one or more bands of an alloy composed of copper and zinc, suddenly cooled after heating, and a cup-shaped sabot cast into a semi-dovetail groove at the base; this is sawed through in several places to permit its more ready expansion; the bands diminish windage and keep the projectile axially in the bore.

Boekel, 1864 (*l*). A flexible metallic casing fits tightly over the rear part of the shell, extending beyond its base; a cup of less diameter rests against the base, and is imbedded in a soft metal packing.

Dahlgren, 1861 (*m*). The cylindrical part of the shell has longitudinal projections fitting the grooves of the gun; and is shouldered to form an abutment for the soft metal sabot, which has an annular groove and is attached to the spheroidal base of the shell.

Hotchkiss, 1865 (*n*). A disk of soft material is interposed between the base-piece and the body of the projectile, to gradually check the forward motion of the base and prevent danger of fracture.

Birney, 1862 (*o*). A tube containing the bursting-charge passes longitudinally through the shell, resting on its base, and is surrounded by an incendiary composition.

Shaffner, 1866 (*p*). The shells contain a bursting-charge of nitro-glycerine in vials packed with gun-cotton and a honeycombed lining of india-rubber, to deaden the concussion and prevent explosion in the act of firing.

Long, 1866 (*q*). The bursting-charge is surrounded by a series of barrels containing several charges of powder and ball, and fired by fuses at the moment when the shell explodes.

2. (*Pyrotechny.*) Shells of paper or wood filled with stars, serpents, or gold-rain frequently form a part of pyrotechnic displays. The first are made by pasting strips of paper in successive layers over a spherical wooden former, each layer being allowed to dry before another is applied; the shell is removed from the mold by cutting it into two parts, which are afterward joined by pasting strips over their edges. Wooden shells are turned in two hemispheres out of poplar or other light wood of sufficient size; these are then united in a similar way. Both kinds are provided with a time-fuse, and fired from a mortar with a small charge of powder.

3. (*Nautical.*) *a*. The wooden outer portion or casing of a block, which is mortised for the *sheave*, and bored at right angles to the mortise for the *pin*, which is the axis of the sheave or sheaves.

Fig. 4980.

Shells.

Fig. 4981.

Shell.

b. A kind of thimble dead-eye block employed in joining the ends of two ropes. In Fig. 4980, *a a'* are sections, and *b b'* plans of shells. In Fig. 4981, 1 represents a joint by a spherical shell, each loop, *a* and *b*, being made by ties and splices, and surrounding the shell *c*. 2 represents a round turn; the cord *a* is passed through the bight of the cord *b* over the button *c*, where it is secured by an ordinary knot.

4. (*Weaving.*) The *upper* and *under shells* are the bars of the *lay*, which are grooved to receive the reed.

5. An engraved copper roller used in calico-printing.

6. (*Optics.*) A concave-faced tool of cast-iron, in which convex lenses are ground. The glasses are attached to the face of a *runner*, which is worked around with a circular swinging stroke, so as not to wear either the glasses or the shell into ridges. See RUNNER.

7. (*Steam.*) The exterior plates of a boiler form the shell.

8. The hard covering of many species of mollusks; employed for various purposes in the arts. Lime is

frequently produced by burning oyster-shells. Another variety yields mother of pearl.

The manufacture of rings for the arms and ankles, from conch-shells imported from the Malayan Archipelago, is still almost confined to Dacca; the shells are sawn across for this purpose by semicircular saws, the hands and toes being both actively employed in the operation. The introduction of circular saws has been attempted by some Europeans, but steadily resisted by the natives, despite their obvious advantages.

9. A coarse kind of coffin; or a thin interior coffin inclosed by the more substantial one.

Shell-au'ger. A wood-boring tool having a large hollow receptacle for the chips. It is used in boring timbers for pump-stocks and wooden pipes. See BIT.

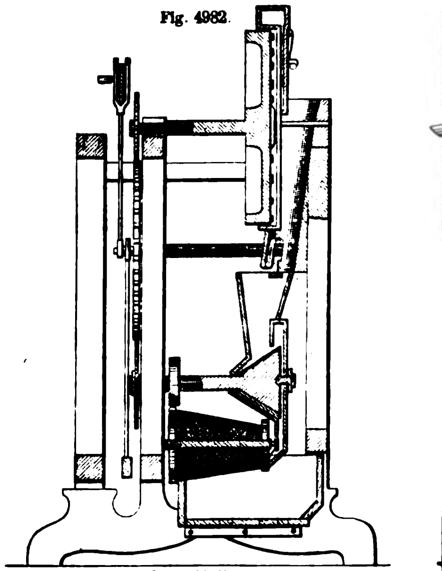
Shell-bit. A wood-boring tool used in a brace. It has a semi-cylindrical form, terminates in a sharp edge, and has a hollow shank. See BIT.

Shell-boat. A boat with a light frame and thin covering; one kind of racing-boat.

Shell-but'ton. A hollow button made of two pieces, front and back, joined by a turn-over seam at the edge, and usually covered with silk or cloth.

Shell'er. (*Husbandry.*) A machine for rasping or rubbing the grain from the cob. In Fig. 4982, the corn is shelled by the revolution of the toothed

Fig. 4982.

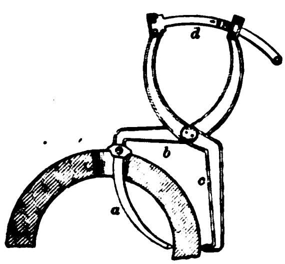


Corn-Sheller.

disk. The grain is conveyed to the grinding hopper, and the cobs are thrown out by a spring worked automatically. See also CORN-SHELLER, page 628.

Shell-fou-gasse'. (*Fortification.*) A mine charged chiefly with shells and covered with earth.

Fig. 4983.



Shell-Gage.

Shell-gage. (*Ordnance.*) An instrument for verifying the thickness of hollow projectiles. It is provided with a set of removable curved arms *a*, each corresponding to a particular kind of shell, which screw into a socket on the leg *b* of the calipers, and are inserted within the fuse-hole of the shell. The thickness of the wall is measured between the points of the arm *a* and leg *c*. The arc *d* is graduated so as to show the proper thickness for each caliber, any deviation from which beyond certain limits causes the rejection of the shell.

Shell-gold. Chips or thin lamina of gold prepared by beating; applied to surfaces for decorative purposes.

Shell-gun. (*Ordnance.*) One for throwing shells or bombs.

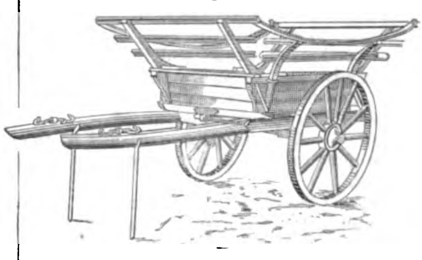
Shell-hook. (*Ordnance.*) A pair of tongs with hooks which are inserted into the ears of a shell and by which it is carried to the mortar.

Fig. 4984.

Shell-Pump.

Shell-pump. (*Well-boring.*) A tube with a clack-valve at its foot, used for removing the detritus from a bored shaft. A hollow cylinder having an inwardly opening valve at bottom, attached to the lower end of the boring-rod for the purpose of bringing up comminuted material. See SAND-PUMP.

Fig. 4985.



Shelving.

Shelv'ing. 1. (*Husbandry.*) Additional top rails to a cart or wagon for enabling it to hold a larger load of bulky material, such as straw, sheaves, or hay.

2. Arrangement of shelves in a store or wareroom, to hold goods or stock.

Sheth. That portion of a plow — sometimes called the post or standard — which is attached at its upper end to the beam and at points below affords places of attachment for the share, mold-board, and landside in ordinary plows. In shovel-plows it fills a similar function as the part to which the share or shovel is secured.

Shield. 1. (*Weapon.*) A portable defensive armor carried in front of the person.

The ancient Greek shield, as described by Homer, was long enough to cover the man from the face to the knee. This was exceeded by the *pavise* of the Middle Ages, which was as tall as a man, and was carried by a *pavisor*, who therewith shielded an archer. It was also carried in assaults on fortifications.

The Roman troops were drilled in modes of combining their shields so as to make a carapace, each soldier holding his shield aloft, the shields overlapping in such a manner as to glance off arrows and other missiles. It was called a *testudo*, from its resemblance to the back of a tortoise.

The shield of the Roman legionary was of wood covered with leather, and studded with metal; it was 4 feet by 2½.

The shield of the ancient Briton was round and of basket-work.

The Norman shield was kite or pear shaped.

In the time of Edward IV. it had become triangular.

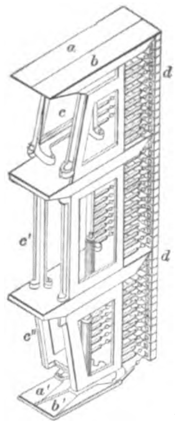
In South Africa it is made of rhinoceros hide.

The shield fell out of use when the broadsword was exchanged for the small sword and rapier. The introduction of fire-arms has farther changed the tactics, and the shield is a thing of the past with civilized nations.

It would be a grateful accessory to the sharpshooter under some circumstances.

2. (*Hydraulic Engineering.*) The shield used by

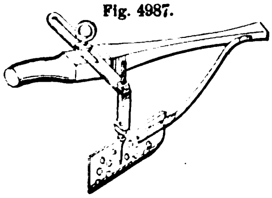
Fig. 4986.



Brunel's Shield (Thames Tunnel).

Brunel during the excavation of the Thames tunnel consisted of a strong iron framing, divided into compartments *c c' c''*, within which the men worked. The top and bottom were formed of independent sections *a a' b b'*, which were advanced alternately by means of jack-screws, and the front was protected by ranges of boards *d d*, which were separately removed to enable the men to excavate the mass of earth in front by small portions at a time, and then replaced as the sections advanced to secure the soft ground from pressing into the shield. The arch of brick was built in behind as the shield advanced.

Fig. 4987.



Shield for Corn in Plowing.

3. (*Husbandry.*) A fender-plate attached to the share of a corn-plow to keep clods from rolling on to the young plant.

Shield-ship. (*Nautical.*) One carrying movable shields to protect the heavy guns except at the moment of firing. This was superseded by the Timby turret, or revolving tower.

Shift. 1. (*Break-joint.*) A mode of arranging the tiers of plates, bricks, timbers, planking, etc., so that the joints of adjacent rows shall not coincide.

In wooden ships, the *shift* is so arranged that in any given cross-section there are at least four *strakes* of plank to one *butt*.

In brickwork the joint is alternate. See Bond.

2. (*Mining-engineering.*) A *fault* or dislocation of a lead, seam, or stratum, accompanied by depression of one portion, destroying the continuity. A *slip*.

3. A turn of men; as a *day-shift* and a *night-shift*. A *double shift* or *single shift* indicates two sets or one set of men to a work. A *three-turn shift* consists of three relays, working eight hours each.

Shift'er. (*Knitting-machine.*) One of the beardless needles (or awns, as they have no eyes) which, by suitable mechanism under the control of their attendant, operate to disengage the outer loops of the course and put them on the next inner or the next outer needles for narrowing or widening.

Shift'er-bar. (*Knitting-machine.*) A bar having stops or projections, whose office it is to stop one needle-carrier bolt while they lift the other needle-carrier bolt.

Shift'ing. (*Nautical.*) The parting of tackle-blocks which have been pulled together. *Fleeting.*

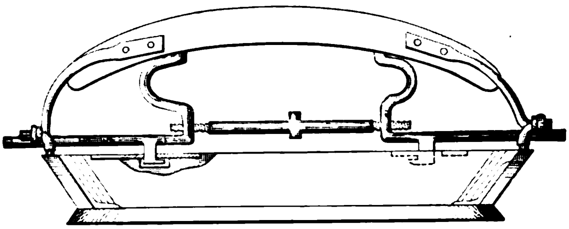
Shift'ing-bar. (*Printing.*) A cross-bar removably dovetailed into a *chase*.

Shift'ing-gage. An adjustable gage.

Shift'ing-plank. (*Ordnance.*) An oaken plank 6 feet in length by 1 foot wide and 2¼ inches thick, and beveled at each end; used, in conjunction with the rollers, blocks, and other implements for mechanical maneuvers, for shifting cannon from one level to another.

Shift'ing-rail. (*Vehicle.*) An upper rail or lazy-

Fig. 4988.



Shifting-Rails for Carriage-Tops.

back to a buggy or carriage, removable at pleasure. In the example, the upper rail is detached from the seat by the disengagement of its feet from the slots in the upper edge of the seat, back, and sides.

Shim. 1. (*Machinery.*) A thin piece of metal placed between two parts to make a fit. It is sometimes used in adjusting the parts of a journal-box to the crank pin or wrist either in the original fitting or in taking up lost motion.

2. (*Stone-working.*) One of the plates in a jumper-hole to fill out a portion of the thickness not occupied by the *wedges* or *feathers*.

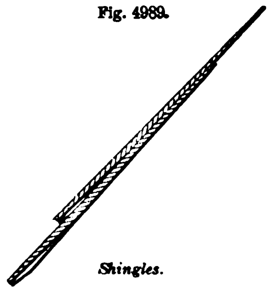
3. (*Agricultural.*) A shallow plow for breaking the surface of land and killing weeds.

Shin. (*Railway-engineering.*) A fish-plate.

Shin-boot. (*Menage.*) A horse boot having a long leather shield to protect the shin of a horse from being injured by the opposite foot; used on trotting horses.

Shin'gle. (*Building.*) A thin piece of wood, having parallel sides and thicker at one end than the other; commonly used as a roof-covering, instead of slates, tiles, or metal.

Fig. 4989.



Shingles.

Shingles are made either by riving and shaving, or sawing; or they are sawed and planed; or they are cut from the steamed block by powerful knives.

Shingles are laid with one third of their lengths to the weather. They are usually 18 inches long, and so have 6 inches of *margin*; this is the *gage* of the shingle; the other two thirds is *cover*. The excess over twice the *gage* is the *lap* or *bond*.

The width of a shingle is about 6 inches in the mode of counting, so that a shingle of 12 inches running width counts as two. Boxes of a given size are made to pile them in, which saves trouble in counting; the clamp or yoke is then put around them, and the bunch removed. See patent 72,581 of 1867.

Pliny says that the best shingles are made of oak, but they are more easily cut from pine. He cites Cornelius Nepos to the effect that down to the time of the war with Pyrrhus, Rome was roofed solely with shingles, a period of 470 years. It is to be presumed that they gave way to tiles, which maintained their supremacy in Europe till the introduction of slate.

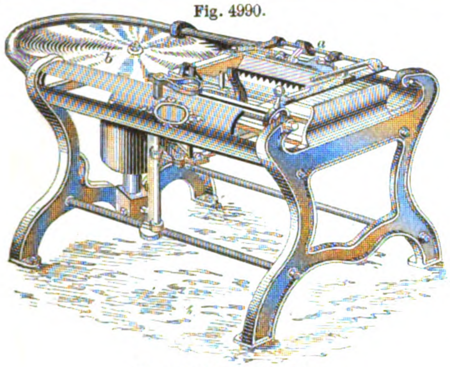
Machines are made for *riving*, *sawing*, *cutting* shingles; also for *planing* and *jointing* the rough shingle.

Shin'gle-joint'ing Ma-chine'. A machine for truing the edge of a rough shingle. It is of the nature of a saw or a circular planer, and acts upon the edge of the shingle, which is pushed along the bench.

Shin'gle-ma-chine'.

In the example (Fig. 4990). the shingle-block is held by jaws in a carriage *a* which reciprocates to and fro over the horizontal

Fig. 4990.

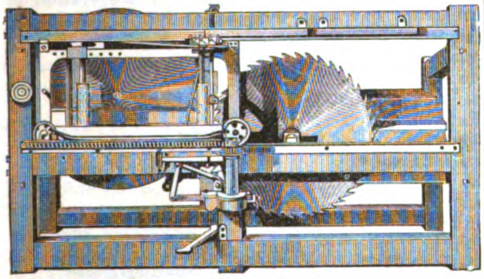


Evarts' Shingle-Machine.

saw *b*. As it makes the feed-stroke, the saw cuts a shingle from the block, and as the carriage *a* returns, the table tilts, a jaw opens and drops the block; the jaw being closed, the carriage is again pushed forward to have a shingle sawed from the lower edge of the block; on its return the table is tilted in the other direction, so as to cut shingles, *butts* and *points*, from the block. To alter the thickness of the shingle, turn the set-screws in the tilting-table up or down, as the case may be. To alter the taper, turn the set-screws in the tilt-handle.

Fig. 4991 is a machine in which the circular saw and jointer are on the same frame. The block is held by spiked rolls in a carriage which presents the bolt, butts and points alternately.

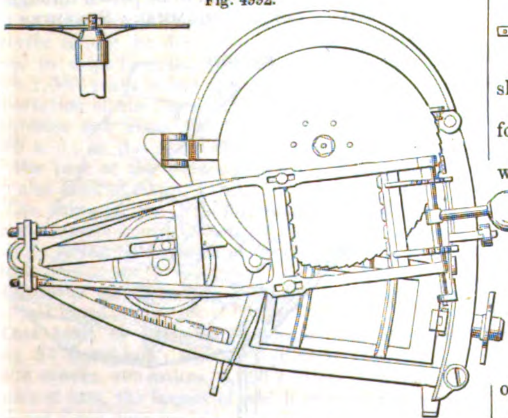
Fig. 4991.



Parker's Shingle-Machine.

The saw used has a diameter twice the length of the shingle to be sawed, and the block is presented sideways to the saw, so that the cuts of the teeth are nearly parallel with the fibers of

Fig. 4992.



Shingle-Machine.

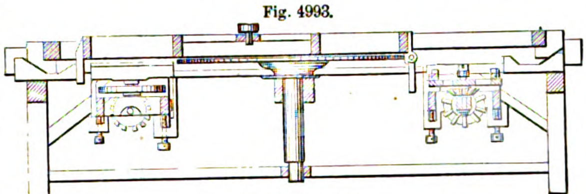
the wood. The result is a smoother surface, approximating that of a shaved shingle.

In Fig. 4992, the machine has an automatic clamp and a tilting frame; the bolt is fed automatically to the circular saw at a comparatively slow speed, and returned at a faster rate. The saw is formed of circular segments around the blades, which form a chute to carry off the sawdust. At the end of its back stroke the counterbalance rises, unclamps the block, which drops, and is reclamped when the effective stroke commences. The belt-frame is oscillated by a crank which is operated by a worm-wheel and belt from the saw-shaft.

Fig. 4993 is a longitudinal section of a machine with two bolt-clamps, running together, one block yielding a shingle as the carriage passes in one direction, and the other, on the return, being presented to the saw on the opposite side. The reciprocating block-carriage is supported on a tilting track alternately inclined to the plane of the saw in opposite directions. The blocks are tilted by a rotary table, so that the butts are cut from alternate ends of the blocks.

Fig. 4994 is a top view of a machine of this description. The bolt-carriage is reciprocated by means of a cross-head with a straight slot in which works the wrist-pin of a crank which gives to the carriage an unequal progressive reciprocation; the diamond-shaped slot in connection with the wrist-pin of the crank working therein gives uniform feed to the bolt-carriage. The dogging devices act automatically and operate by weight

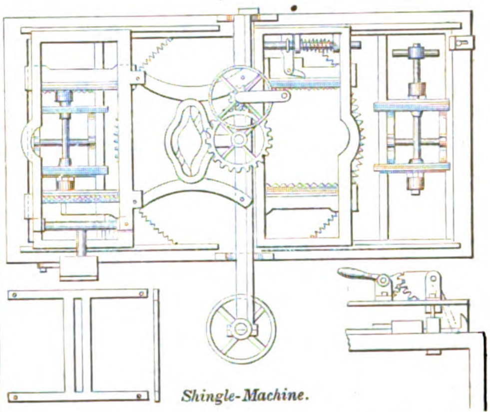
Fig. 4993.



Shingle-Machine.

and spring respectively. The two double taper-cams on one shaft alternately tilt the block to give taper to the shingles.

Fig. 4994.



Shingle-Machine.

Shin'gle-mill. A saw-mill for cutting logs into shingles.

Shin'gle-nail. A cut nail (6*d.*) of proper size for fastening shingles on a roof.

Shin'gle-plan'ing Ma-chine'. A machine in which roughly rived or sawn shingles are faced by planing in the direction of the grain of the wood.

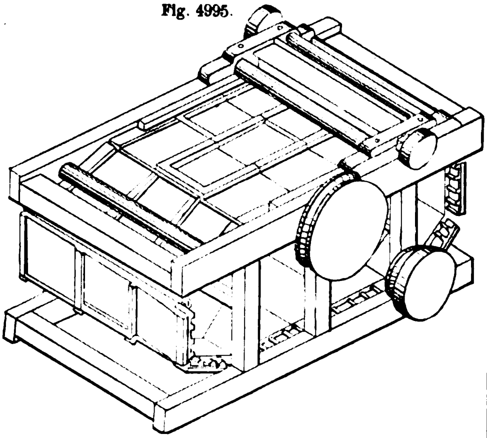
In Fig. 4995, the shingle blank is placed in one of the wedge-shaped pockets on the outer surface of the endless carrier, and passes beneath the rotary cutter, which removes the portion above the carrier.

There are other forms of planing-machines specially adapted for surfacing shingles.

Shin'gler. An eccentric wheel or roller revolving within a concave and pressing the dross out of the *loop* or *ball* from the puddling-furnace.

In the figure, the *loop a* is pressed between the three cam-rolls *b c d*, the first of which has a collar *b'*

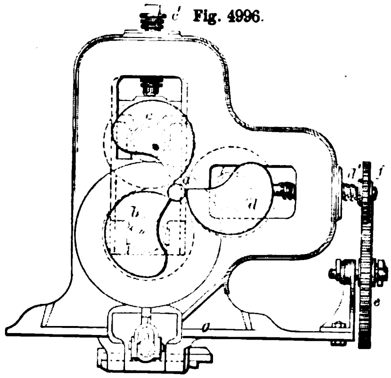
Fig. 4995.



Shingle-Planing Machine.

at each end, between which the other two work; *c* is adjustable by a screw *c′*, and *d* is backed by a screw *d′*, which yields when the thickness of the bar is excessive, and is brought back to place by a weighted lever on the axis of the wheel *e*, which engages with the pinion *f* that turns the screw.

Fig. 4996.



Brown's Shingler.

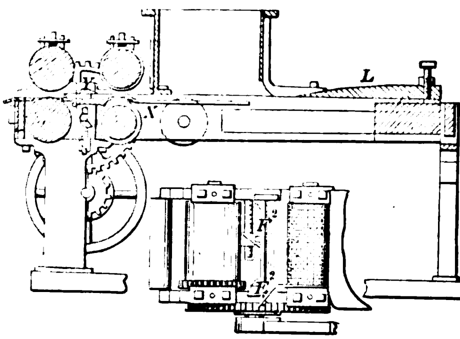
The squeezed bar drops on to the bed-plate *g* of the machine, and is then pressed longitudinally by a bell-crank lever device. See SQUEEZER; TRIP-HAMMER; STEAM-HAMMER.

In Siemens' process for shingling and compressing puddled balls, the ball is placed on a turn-table and subjected to the pressure of three or more hydraulic rams advanced simultaneously toward it horizontally in radial directions. The pressure being relieved and the rams withdrawn by counterweights and springs, the turn-table is partly turned so as to present fresh portions of the ball to the rams, which are again advanced. When the ball has thus been squeezed all round, a ram or screw head is brought to bear on it vertically, and the rams are advanced with a higher degree of pressure, after which the consolidated metallic mass is withdrawn to be rolled, hammered, or converted into steel. To economize power, two sources of hydraulic pressure are employed, the one giving a low pressure for the first part of the operation, and the other a much higher pressure for completing it. Instead of using a number of separate hydraulic cylinders, the several pressure-heads may be worked from one hydraulic cylinder, or by steam or other power.

Shin′gle-riv′ing Ma-chine′. One in which a block is fed to the knife, or the knife to a block, from which a shingle is split with the grain. See also SHINGLE-MACHINE.

In the example (Fig. 4997), the block lies in the hopper, and a portion projecting below is split therefrom between the stationary and reciprocating knives

Fig. 4997.



Shingle Riving and Planing Machine.

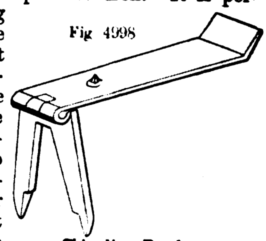
X L, which are in the same plane. The blank is then forced to the feed-rollers, which carry it between the upper and lower shaving-knives and the edging-knives E^2 F^2; the upper knife *Y* is gradually depressed to give the taper to the shingle passing endwise beneath it. The shingle is split, shaved, tapered, and jointed at one continuous operation.

Shin′gle-saw. See SHINGLE-MACHINE.

Shin′gle-trap. (*Hydraulic Engineering.*) A structure of posts or piles and boards fastened thereto, raised some distance above the surface of a beach, and operating to catch shingle, sand, and silt, so as to prevent the denudation of the shore and the encroachment of the sea upon the land. See GROIN.

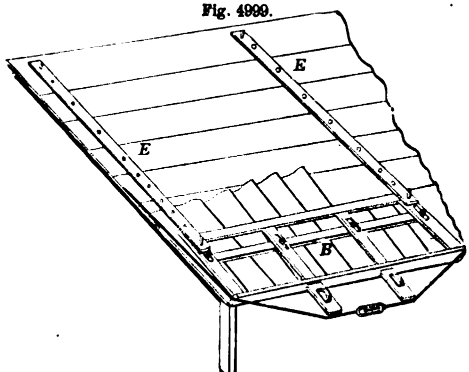
Shin′gling. (*Iron-working.*) The operation of removing slag, etc., from puddled iron. It is performed in a strong *squeezer*, or under the trip-hammer. Its object is to press out as perfectly as practicable the liquid cinder which the ball still contains; it also forms the ball into shape for the puddle-rolls. A heavy hammer effects this object most thoroughly, but not so cheaply as the squeezer. The ball receives from 15 to 20 blows of a hammer, being turned from time to time as required; it is now termed a *bloom*, and is ready to be rolled or hammered; or the ball is passed once through the *squeezer*, and is still hot enough to be passed through the puddle-rolls. See TRIP-HAMMER; SQUEEZER; STEAM-HAMMER.

Fig. 4998.



Shingling-Bracket.

Fig. 4999.



Shingling-Gage.

Shin'gling-brack'et. A device to enable a carpenter to stand on a roof while nailing on shingles.

Shin'gling-gage. A device for adjusting shingles in the proper position for nailing. In the example, the butts of the shingles are placed against the bar *B*, which is adjusted by the gaging-straps *E E* after each course of shingles is nailed.

Shin'gling-ham'mer. (*Metal-working.*) The tilt or other power hammer which acts upon the ball from the puddling-furnace and forces some of the remaining impurities therefrom. The iron is converted into a *bloom*, which may be rolled at the same heat and be thereby converted into bar-iron. The bars may be cut and made into *fagots* or *piles* for reheating and rerolling. For some purposes, or with some qualities, the bars, after the single rolling, are in a merchantable condition.

Blooming is used as synonymous with *shingling*, and is sometimes called *tilting*, as it was always performed with a tilt-hammer until the steam and other power hammer and squeezers were introduced.

Shin'gling-hatch'et. A tool with a poll, used in nailing on shingles, a bit for occasionally trimming them to fit, and a claw for drawing the nails.

Shin'gling-mill. (*Metal-working.*) A rolling-mill or forge, where puddled iron is hammered to remove the dross, compact the grain, and turn out malleable iron.

Shin'gling-tongs. Heavy tongs, usually slung from a crane and used in moving the ball of red-hot iron to and beneath the trip or steam hammer.

Ship. (*Nautical.*) A three-masted vessel, with square sails on each mast.

Noah's ark being 300 cubits long, 50 broad, and 30 high, and the cubit being that estimated by Mr. Greaves, would make the ark 547 feet long, 91 feet 2 inches wide, and 54 feet 8 inches high. 25,820 tons capacity.

The proportions are relatively much like those of the "Great Eastern," which was about 18,000 tons.

Ships with masts, yards, and square sails are shown in the ancient paintings of Eléythya, Egypt.

The Bible and other historical authorities agree in giving precedence to the Phœnicians in the matter of maritime navigation. Jacob (1689 B. C.), in assigning prophetically the dwelling of Zebulon, placed him "at the haven of the sea, and he shall be for a haven of ships, and his border unto Zidon." Zebulon failed, it may be mentioned, to possess the land assigned to the full extent. The same may be said of Dan, Simeon, and other tribes for a period of nearly five hundred years after Joshua led them across Jordan.

The prophecy of Balaam, about 1452 B. C., that Assyria should be destroyed by people who should come in ships from the coast of Chittim, was more than 1,000 years before the accomplishment. The deportation of the Jews to Egypt in ships under the Ptolemies and Titus was foretold by Moses, about 1450 B. C., as the result that follows unfaithfulness on the part of the people whom he led and served. See also Ezekiel, chap. xxvii.

The ships on the Nile for navigating during the inundation are from 10,000 to 24,000 bushels burden.

Some of the Nile vessels in former times were very large.

Diodorus mentions one built by Sesostris, about 478 feet long.

One built by Ptolemy Philopater was 420 feet long, 57 feet beam; was 83 feet high, and carried 4,000 rowers, 400 sailors, 3,000 soldiers. It had 40 banks of oars, the largest of which were 57 feet long and weighted with lead in the handles.

The royal barge on the Nile was nearly as large.

The galley built under the superintendence of Archimedes for Hiero, of Syracuse, was constructed by Archias of Corinth. It had 20 tiers of oars and 3 decks, the middle deck having on each side 15 dining-apartments, besides other chambers, sumptuously furnished, and the floors paved with mosaics from the story of the Iliad. On the upper deck were gardens with arbors of ivy and vines, and a temple of Venus paved with agates and roofed with cypress wood. It was adorned with pictures and statues, and furnished with couches and drinking-vessels. It had a library, baths, cabins for the soldiers, and stabling for 20 horses. In the forecastle were 2 immense cisterns, one of fresh water for consumption, and the other of salt water for a fish-pond. From the sides of the vessel projected ovens, kitchens, mills, and other offices built upon beams, and each supported by a caryatid 9 feet high.

Around the deck were 8 wooden towers for defense, the garrison of each being 4 soldiers and 2 archers. On this upper deck was the catapult for hurling stones of 300 pounds weight, and the ballista for throwing darts 18 feet long a distance of 300 yards.

The ship had 4 anchors of wood and 8 of iron, and the pump for removing bilge-water was the Archimedean screw. The crew for evolutions was 600 men, and the commissaries' stores included 60,000 bushels of corn, 10,000 barrels of salt fish, and 20,000 barrels of salt meat. She was at first called the "Syracuse," and afterward the "Alexandria." The mainmast came from England.

Hiero became tired of his great toy, and put the vessel to carrying corn. Finding the draft of water too great to enter any of the surrounding harbors, which detracted from its usefulness, he had to get rid of it like a king; so he loaded it with corn and sent it to Alexandria (coals to Newcastle), as a present to Ptolemy, king of Egypt, who admired. examined, emptied it, and hauled it on shore, and then forgot it. So does history, for that is the last we hear of it.

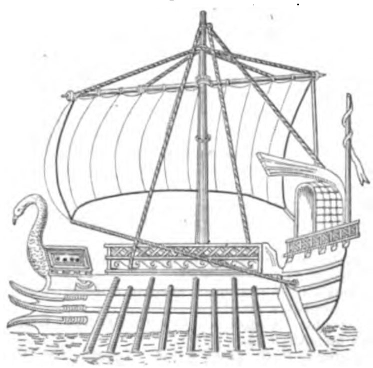
The penteconter is mentioned by Herodotus (I. 152). It had 50 rowers, who sat 25 on a side, on thwarts of the same level. The navy of Polycrates consisted of penteconters.

Biremes, where the rowers sat in 2 ranks, on different levels, were probably invented by the Phœnicians, and were known to the Assyrians in the time of Sennacherib. One is represented in the palace of that monarch at Kouyunjik.

Triremes were invented by the Corinthians about 750 B. C.

Fig. 5000 is a view of a Roman *biremis*, or two-banked galley. The Romans, by the account of Livy, first became aware of the importance of a fleet during the second Samnite war, B. C. 311.

Fig. 5000.



Roman Biremis.

As their colonies spread, especially when the Pontian Islands were embraced in their bounds, the necessity grew. In the time of the first Punic war the Romans became a maritime power, clearly foreseeing that in default of a navy Carthage could not be subdued. See also Smith's "Dictionary of Greek and Roman Antiquities," p. 783 *et seq.*

A. D. 1500. The "Great Harry," constructed by Henry VII., was the first ship of the English royal navy. Previous to this the navy consisted of vessels furnished by certain maritime towns.

1515. The "Henry Grace de Dieu," of 1,000 tons and 122 guns, mostly of small caliber, was built under the orders of Henry VIII. It was a sea-going failure

The "Caraçon," built by Francis I., ditto.

1603. The English navy consisted of 42 ships.

1610. The "Prince," 1,400 tons, built by James I.

The "Carrack" was a large ship. The "Santa Anna" was the property of the Knights of St. John, of about 1,700 tons, sheathed with lead, and built at Nice, 1530. It was a floating fortress, and aided Charles V. in taking Tunis in 1535. It had a crew of 300 men, and 50 pieces of artillery.

Of celebrated voyages may be mentioned that of the Phœnicians in the time of Pharaoh Necho (B. C. 610) in circumnavigating Africa.

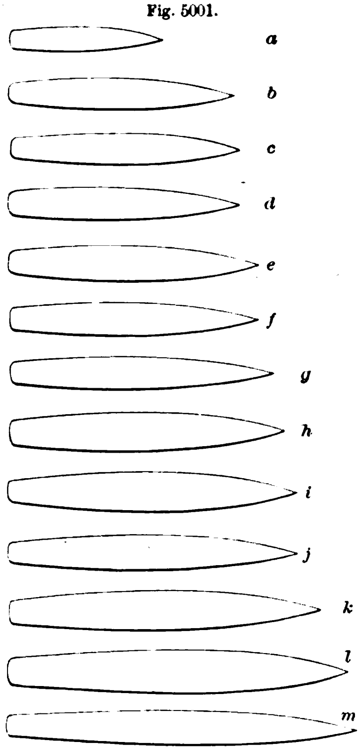
Christopher Colon in crossing the Atlantic, 1492.

Vasco de Gama in doubling the Cape of Good Hope, November 20, 1497.

Ferdinand Magellan in discovering the Pacific Ocean, into which he sailed from the Straits of Magellan, November 28, 1520, and which he named the Pacific Ocean. He sailed across the Pacific, reached the Ladrones, was killed by mutineers; the vessel anchored at Tidore, November 8, 1521, having been at sea 27 months.

Sebastian de Elcano, Magellan's lieutenant, doubled the Cape of Good Hope, and on September 7, 1522, the "San Vittoria" anchored at St. Lucar, near Seville, Spain; the first circumnavigation of the earth.

Fig. 5001.



Proportions of Ocean Steamers.

a, "Baltimore," N. G. Lloyd's line. Length, 185 feet; beam, 29 feet; length to breadth, 6·38.

f, "Rhein," N. G. Lloyd's line. Length, 332 feet; beam, 40 feet; length to breadth, 8·30.

g, "Westphalia," Hamburgh line. Length, 340 feet; beam, 40 feet; length to breadth, 8·50.

h, "Pennsylvania," American S. S. Co. Length, 343 feet; beam, 43 feet; length to breadth, 7·91.

i, "Russia," Cunard line. Length, 358 feet; beam, 43 feet; length to breadth, 8·33.

j, "Queen," National line. Length, 358 feet; beam, 41 feet; length to breadth, 8·73.

k, "Ville du Havre," French line. Length, 423 feet; beam, 49 feet; length to breadth, 8·63.

l, "City of Montreal," Inman line. Length, 433 feet; beam, 44 feet; length to breadth, 9·84.

m, "Atlantic," White Star line. Length, 435 feet; beam, 41 feet; length to breadth, 10·61.

The following works on seamanship may be consulted: —

Falconer's "Dictionary." "The Ship, its Origin and Progress." Steinitz. London, 1849. "Sheet Anchor." Lever. London (Am. ed.), 1854. "Kedge Anchor." New York, 1852. Luce's "Seamanship." Newport, R. I., 1863. Young's "Nautical Dictionary." London, 1863. Totten's "Naval Text-Book." New York, 1862. "Sailor's Word Book." Adm. Smyth. London, 1867. "Shipbuilding," by Rankine, Watts, Barnes, and Napier. Wiley & Sons. New York.

In Plate LIX., the upper figure is a longitudinal midship section of a steam sloop-of-war, carrying 22 guns. Vessels of this class are of 1,100 to 1,200 tons measurement, and have engines of 200 to 300 horse-power.

The next view shows the gun or spar-deck plan of the same.

The lower or berth deck is not shown by plan view. It contains the cabins, state-rooms, and accommodations for officers and crew in vessels of this class.

The sectional plan of the upper hold shows the arrangements of the lower deck, the bins for stores, stowage of the hatch, chain-cable lockers, arrangement of boilers, and general distribution of fuel; also magazine and shell-room.

The plan of lower hold shows the arrangement of keelsons, engine-bearers, and boiler-bearers, stowage of tanks and provisions in fore-hold, and details of magazine and light-room.

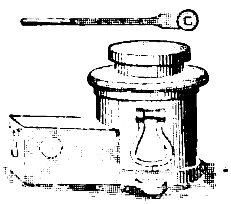
Ship'build-ing-dock. A chamber with a floor and walls of stone masonry, having an opening toward the adjoining harbor, which can be closed when required by a pair of folding gates or by a floating caisson gate. The size is according to the length and beam of the vessel designed to be built in it. The sides slope off in a series of steps at about an angle of 45°, so as to form abutments for shores and scaffolding. The width at top is equal to the width at bottom plus twice the depth. See also DRY-DOCK; GRAVING-DOCK.

Ship-jack. A compact and portable form of hydraulic jack, adapted for lifting ships and other heavy objects; the number required being proportionate to the weight. The launch of the "Great Eastern" was ultimately effected by the employment of these jacks.

Fig 5002.



Ship-Jack.

Ship-pen'du-lum. A pendulum with a graduated arc, used in the

navy to ascertain the *heel* of a vessel, so that allowance may be made in laying a gun for the inclination of the deck.

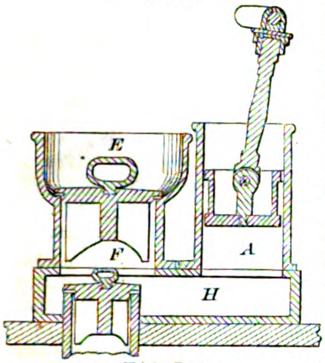
Ship's Ar′mor. See ARMOR-PLATING.

Ship's Berth. (*Nautical.*) *a.* The position occupied by a ship in an anchorage or dock or beside a wharf.

b. A standing bed-place on shipboard.

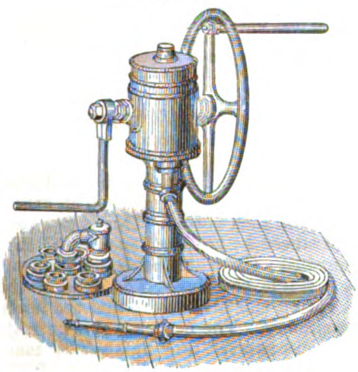
Ship's Pump. A suction-pump for freeing a ship's hold from water. That illustrated is provided with a chamber *H* above the deck, with which the head of the pump-barrel and foot of the suction-tube *A* communicate. The cover *E* and valve *F* are removable, so that ready access may be had to the interior of the pump. Downton's pump is used in the British navy as a bilge, deck-washing, and fire-engine pump. It has three buckets, one above another, in the barrel, and an air-chamber in the head, so as to discharge a continuous stream of water. When fitted with deck or suction plates, it is capable of drawing water from three to six different parts of a vessel.

Fig. 5003.



Ship's Pump.

Fig. 5004.



Ship's Pump with Hose.

Ship-thim′ble. (*Nautical.*) An eyelet or metallic grommet, forming an eye in a sail or to a rope.

Ship′wright's Tools. See WOOD-WORKING TOOLS AND MACHINES.

Shirr. (*Fabric.*) An elastic cord inserted in cloth or between two pieces. See RUBBER THREAD.

Shirred Goods. (*Fabric.*) Goods with elastic cords (*shirrs*) interwoven in suspenders, garters, etc.

Shirt′ing. (*Fabric.*) Bleached or unbleached cotton cloth, of quality and texture suited for undergarments.

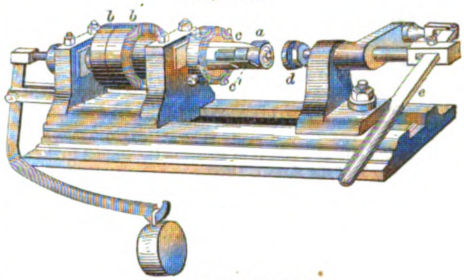
Shive. 1. A bung.

2. The scale or bark removed from the fibrous portion (*hare*) of hemp and flax in *braking*.

3. A SHEAVE (which see).

Shive-cut′ting Ma-chine′. (*Wood-working.*) A machine for cutting shives or bungs. It has heads *a* and *d*, between which the board, out of which the bungs are to be cut, is placed. The cutters *c c′* are on a hollow spindle, which is rotated by a band on the pulley *b*. *b′* is a loose pulley. The board to be cut being in position, the lever *e* is moved, driving forward the head *d* and forcing the board against

Fig. 5005.



Shive-Cutting Machine.

the head *a*, which retreats, allowing the cutters *c c′* to make an annular groove, which goes through the board and produces a bung. The lever is then backed; the head *a* is advanced by means of the weight, which acts upon the rear of the spindle, and the bung is forced from between the cutters and drops to the floor.

Shiv′er. 1. A small *sheave.*

2. A small wedge or key.

Shoad; Shode. (*Mining.*) Surface ore in pieces mixed with other matters, and indicating the *outcrop* of a lode or vein in the vicinity.

The method of finding the vein by tracing the *shoadstones* to their source at the *strike* is called *shoading.* Holes dug to prospect or intercept the vein are called *shoad-pits.*

Shoal-a-larm′. An audible alarm consisting of a bell, whistle, or trumpet, rung or blown by power derived from the rocking of the vessel, which is moored at the shoal, or by machinery moved by the current, tide, or wind. See FOG-ALARM.

Shoal-in′di-ca′tor. (*Nautical.*) A buoy or beacon placed upon a shoal to indicate its position to mariners.

Shock. 1. (*Husbandry.*) *a.* A collection of *sheaves* standing together in the field, for the grain to ripen. Called in England a *shook* or a *stook.* It has usually twelve sheaves, but customs differ.

b. A collection of cut stalks of corn standing in the field around a central core of four stalks, whose tops are diagonally woven together and bound at the intersection. This central support holds the stalks while they are being set up, and is called a *gallows.* The shock should be bound when about one third of the stalks are in place, and bound again when all are gathered. It should be of a conical form when completed.

2. See SHOOK.

Shod′dy. (*Fabric.*) A cloth made from worn woolen rags. These are torn to pieces by a machine having spiked rollers (termed a devil), cleansed, and the fiber spun with a certain proportion of new wool, the yarn being afterward woven into the full-bodied but flimsy fabric, termed shoddy.

Mungo is made from tailors' clippings similarly treated.

Sho′der. (*Gold-beating.*) The package of gold-beater's skin employed in the second stage of gold-leaf making. The first package is the *kutch.* The last is the *mold.*

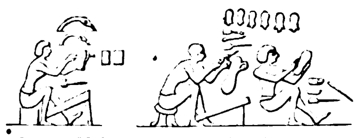
Shoe. 1. (*Apparel.*) *a.* A covering for the foot, made of leather in Europe, America, and some other parts; of paper and various fabrics in China and Japan; of wood in Holland and France (sabots); of dressed skins among the North American Indians (moccasins).

A shoe has a thinner and more elastic leather for the upper, and one or two thicknesses of thicker leather for the sole. The parts are united by stitches, pegs, nails, screws, cement. See BOOT; MOCCASIN; SABOT.

Among the interesting series of trades practiced by the Egyptians in the times of Joseph and of Moses, and illustrated in the tombs of Thebes and elsewhere, are shown the shoemaker at his bench engaged in boring a leather sole with an awl. The latter is also represented, as also two pieces of leather not yet cut to shape, and two thongs ready twisted, which are to be attached to the sole as a means of securing the sandal to the foot. The painting is of the time of Thothmes III., the contemporary of Moses, 1490 B. C.

Another shoemaker's shop is represented in a Theban painting, where a larger stock and selection of tools are shown. Two men are employed; one is piercing the side piece by which the thongs are attached to the soles, and the other tightening the thread in the time-honored way, gripping it by the teeth. The tools are a mallet, bent and straight awls, a scraper, and a tool like a comb, which probably had a row of points for marking the places for piercing with the awl.

Fig. 5006.



Sandal-Makers and Shoemakers in Thebes.

In Dr. Abbott's collection of Egyptian antiquities, now in the possession of the Historical Society of New York, are a number of shoes which have survived the lapse of centuries. While many of them are shriveled, dried, and dilapidated, sufficient remains to identify their form and mode of construction. The most interesting one is yet occupied by the foot of a mummy. The bones and dried integuments reveal a form of extreme elegance, with a highly arched instep and feminine grace and proportions. The material of the shoe has become brittle by the desiccation of perhaps 25 centuries, and is falling to pieces. It appears to have been of kid, but is securely locked in a case, and does not admit of very close inspection.

The shoes of the ancient Egyptians were made of papyrus, leather, or textile fabrics. The *upper* was sewed to the *sole*, but an examination of a number of shoes of that ancient people has failed to reveal a *heel*.

The Chinese and the inhabitants of India have had shoes from time immemorial. Skins, silk, rushes, linen, wool, wood, bark, and metal have been used by these Orientals.

The Homeric heroes are represented without shoes. Moses wore sandals or shoes in the wilderness of Sinai. The early Greeks and Romans used them but little; succeeding ages introduced foot coverings of various kinds: the sandal with latchet; the same with a toe-piece or cap; a leather moccasin, or soleless shoe; a shoe in which the toes are exposed (Fig. 4557, *e*); a shoe, as we understand it; slippers; boots; buskins, etc., etc.

The material was of *tanned* or *tawed* skins.

Homer, Ovid, and Pliny agree in celebrating the skill of Tychius, the Bœotian, in the art of shoemaking. The latter credits him with the invention of leathern shoes. It may be supposed that the sandal and moccasin had been in use from time immemorial, and that Tychius united an upper to a sole and formed a shoe.

If so, he had been anticipated in this by the Egyptians.

Artaphernes, speaking to Histiæus, said, "Aristagoras drew the sandal on, but it was of your stitching." See SANDAL.

"Extravagance has descended to our clothes and shoes." — ATHENÆUS.

The Roman senators wore leathern (or skin) boots reaching to the midleg: these were usually black, but Roman magistrates wore red shoes on occasions of ceremony.

The Roman foot-gears were the *calceus*, or shoe, and the *solea*, or sandal. The former had an upper and sole, and was tied upon the instep with a latchet or lacing. See SANDAL.

The *solea* was a cork or wooden sole, covered above and below with leather, and stitched on the edge. It left the upper part of the foot bare, and was secured by straps, which were crossed over the instep and wound about the ankle. No buckle.

The *caliga* was the coarse shoe of the Roman soldier and company officers. The regimental officers, so to speak, wore the *calceus*. The sole of the *caliga* was thickly studded with hob-nails.

Other protections for the foot were the *cothurnus* and the *socca*. See Smith's "Dictionary of Greek and Roman Antiquities."

The shoes of the Emperor Marcus Aurelius had separate compartments for the toes, as we see by a statue of that monarch.

The small shoes and cramped feet of the Chinese ladies cannot be traced farther back than the tenth century A. D.

From the twelfth to the fifteenth centuries shoes were made for the fashionables with long toes, stuffed with *tow*. In the reign of Richard II., the toes of the boots were chained to the knees. In 1493, Parliament limited the length of the *pike*, or useless projection, to two inches.

In the seventeenth century very high heels were in vogue among the English ladies.

See "The Boot and Shoe Makers' Assistant," London, 1853, for an excellent display of early foot-coverings.

The Syrian shoes are made to be easily shifted on and off, as they are left at the entrance to a mosque or room. They are made of various materials for indoor or outdoor wear; leather for the latter. They have boots also, but the representations of their "foot-gear" with which we are favored by travelers make very poor affairs of either shoes or boots, they appearing to have no broad sole, but to resemble heavy moccasins.

Fig. 5007.

Syrian Shoes.

Isambard M. Brunel invented, in 1810, a machine for making seamless shoes. Sir Richard Phillips states as follows, in his "Morning Walk from London to Kew": —

"I was shown his manufactory of shoes, which is full of ingenuity, and, in regard to subdivision of labor, is on a level with the admired manufactory of pins. Every step is effected by the most elegant and precise machinery; while, as each operation is performed by one hand, so each shoe passes through 25 hands, who complete from the hide, as supplied by the currier, 100 pairs of strong and well-finished shoes per day. All the details are performed by the ingenious application of the mechanic powers; and all parts are characterized by precision, uniformity, and accuracy. As each man performs but one step in the process, which implies no knowledge of what goes before or comes after him, so the persons employed are not shoemakers, but invalided soldiers, who are able to learn their respective duties in a few hours. The contract at which these shoes are delivered is 6*s.* 6*d.* per pair ($1.56), being at least 2*s.* (44 cents) less than what was before paid for an inferior article."

Brunel's nailed shoes did not answer the expectations formed of them; the nails were found to penetrate the leather of the soles and hurt the soldiers' feet in marching, so that the scheme was finally abandoned.

Shoes are now largely made by machinery. Several different methods and a great variety of machines are employed. In one process, a thread is cut upon a brass wire, and the screw thus made is forced through the sole and upper placed on an arm beneath and riveted and then cut off. This is repeated as the shoe is advanced by the workman, until the operation is finished; the whole being effected automatically by a single machine. The ends of the wires are then cut off and filed down, and the heels nailed on by machinery. The heels are also burnished and the soles sand-papered and finished by machinery. See NAILING, PEGGING-MACHINE; pages 2161, 2162; also the pages here following.

India-rubber shoes and boots are made by the following process: —

The gum is ground and cleaned.

Is triturated with say 3 per cent of sulphur.

Dissolved in benzine or other solvent.

The *cement* thus obtained is spread upon fabric by rollers; the lower roller carrying the cloth moves slower than the heated upper roller, and thus generates a friction which *grinds* the gum into the cloth.

The cloth is cut by pattern into the required shapes and sizes.

These are united by rubber cement over a last.

They are treated with linseed-oil varnish laid on with a brush.

Put in a heater, 280° Fah., for 7 hours.

b. A *snow-shoe*; a *racket*.

2. (*Farriery.*) A metallic plate nailed to the hoof of a horse, mule, or ox, to preserve the hoof from wear and prevent it from becoming sore. See HORSE-SHOE.

3. (*Machinery.*) *a.* A bottom piece on which a body is supported, as the *ink*, *step*, or support for the lower end of a vertical shaft.

b. A piece on which an object is placed while moving, to prevent its being worn.

4. (*Building.*) *a.* A block or base piece for the reception of a pillar, or on the top of a column for the reception of a truss, girder, or other portion of the flooring or roof-frame.

b. An iron plate having an inclined seat adapted to receive the foot of a rafter.

5. (*Shipwrighting.*) The step of a mast; it rests on the keelson.

6. (*Nautical.*) *a.* The *bill-block.* A wooden piece secured to an anchor during the operation of *fishing*; it holds the point as the anchor rises, and keeps it from tearing the ship's side.

b. A board lashed to the fluke to extend its area and consequent bearing surface when in the ground.

c. A foot-board on which a spar is erected, to act as a jib in hoisting.

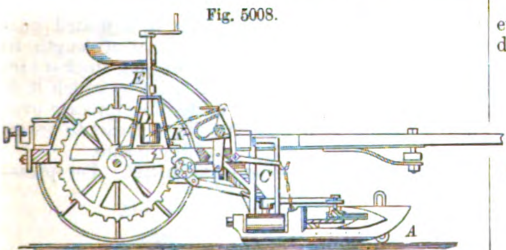
7. (*Wheelwrighting.*) *a.* A strip of wood or steel fastened beneath the runner of a sled or sleigh, to take the wear. Cast-iron soles of a peculiarly hard quality are used to advantage, and are bolted to the runners. Otherwise called a *sole.* See SLED.

b. A drag to receive the wheel of a vehicle to retard the course of the latter in going down hill. But little used in this country, where we have convenient wagon and carriage locks. See WAGON-DRAG.

8. (*Agriculture.*) *a.* The metallic block on the inner end of a finger-bar; it runs on the ground next to the standing grain. To it the finger-bar is hinged in harvesters of the usual construction.

Fig. 5008, *A*, shoe; *C*, bell-crank lever, having attached a chain *K*, which is wound upon the drum

Fig. 5008.



Mowing-Machine.

D on the crank-shaft *E*, to raise the finger-bar from the ground.

b. The shaking portion of a winnowing-machine or grain-separator, in which the grain is separated from the chaff and offal. The shoe is pivoted at one end and oscillated by power applied to the other. It is furnished with riddles and sieves, and the grain, etc., under treatment is subjected to a blast of air from a rotary fan.

9. (*Milling.*) The spout beneath the feeding-hopper which conveys the grain from the latter to the eye of the runner. The shoe is shaken by a *damsel* on the spindle.

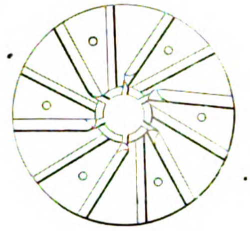
10. (*Mining.*) *a.* An inclined trough used in an ore-crushing mill.

b. A removable piece of iron at the bottom of a stamp or muller in a stamp-battery, ore-grinder, or amalgamator.

11. (*Railway-engineering.*) That part of a car-brake which is brought in contact with the wheel in the act of stopping a train.

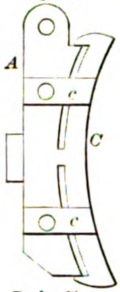
That shown in Fig. 5010 has a metallic sole *C*,

Fig. 5009.



Shoe.

Fig. 5010.



Brake-Shoe.

with arms *c c* embracing the wooden shoe *A*, and having holes to receive pins or blocks which pass through the shoe.

12. The iron point of a pile.

13. The short horizontal section at the foot of a rain-water pipe, to give direction to the issuing water. The top end is the *head.*

Shoe-block. (*Nautical.*) One having two sheaves which revolve in planes at right angles to

Fig. 5011.

Shoe-Block.

Fig. 5012.

Shoe-Stretcher.

each other. They are generally used as *buntline-blocks* to courses, the *buntline* reeving in the upper sheave, and the *whip* in the lower one.

Shoe-brush. Shoe-brushes formerly were always employed in pairs, — a hard brush for removing the dirt and polishing, and a softer one for spreading the

Fig. 5013.

Shoe-Edge Trimmer (Shoe-Machine Manufacturing Co.).

blacking. It is now usual to unite the two, a small circular soft brush being attached to the back of the hard brush, which is frequently provided with a handle. The soft brush is sometimes cylindrical and turns on pivots.

Shoe-butts. (*Leather.*) Stout leather for soles.

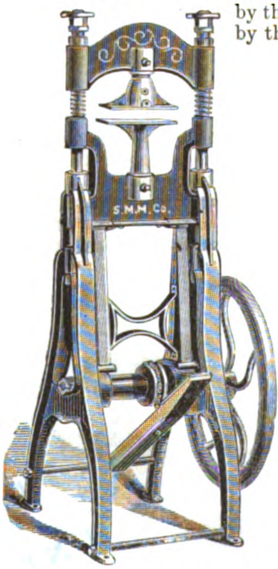
Shoe-clasp. A buckle for closing some kinds of shoes.

Shoe-dis-tend′er. An implement for expanding a somewhat tight shoe. An expanding-last. In the example (Fig. 5012), the cap *D* and heel-plug *C* are driven apart by the action of the screw, and thereby stretch the shoe.

Shoe-edge Trim′mer. (*Shoemaking.*) The shoe is mounted upon a jack, the carriage of which has communicated to it a movement of translation and rotation, so that while the side of the sole is being trimmed, the shoe is fed longitudinally against the knife, but at the toe and heel is rotated beneath it. The knife is universally jointed, to permit the hand of the operator to determine the different bevels cut.

Shoe-em-boss′ing Ma-chine′. (*Shoemaking.*) For embossing boot and shoe fronts with any required ornamental design before they are worked up. It can be made to emboss the fronts of finished shoes by a simple attachment. The upper platen is moved by the treadle and returned by the springs.

Fig. 5014.



Shoe-Embossing Machine.

Fig. 5015.

Shoe-Eyeleting Machine.

Shoe-eye′let-ing Ma-chine′. Eyelets are fed one by one from the reservoir at the top, down the inclined ways, and are seized at the foot between the plunger and anvil, and riveted in their proper places in the shoe or strip of leather, which is held and fed by the operator.

Shoe-fast′en-er. A device for closing a shoe. A button-hook.

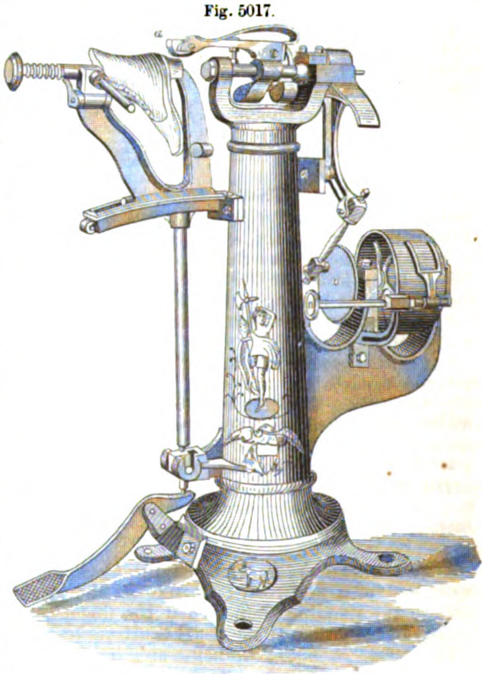
Fig 5016.

Shoe-Hammer.

Shoe-ham′mer. A hammer with a slightly convex, broad face, and a wide, thin, rounding peen, whose length is transverse to the handle. Used in pounding leather upon the lapstone, to condense its pores. Also in driving pegs. The peen is used in pressing out the creases incident to the crimping of the leather.

Shoe-heel Bur′nish-ing-ma-chine′. A machine in which a shoe or boot is chucked and revolved against a burnishing-tool. The one shown

Fig. 5017.

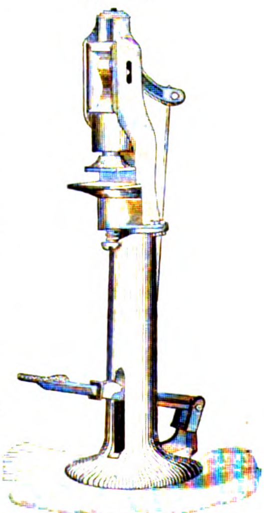


Shoe-Heel Burnishing-Machine.

in Fig. 5017 uses a *hot-kit*, that is, a heated burnisher. A flexible gas-pipe of sufficient length to follow the oscillations of the burnishing-stock *a* carries to the interior of the tool a jet by which it is kept heated. The tool is made to reciprocate over the surface of the heel, passing from breast to breast at each oscillation with an elastic pressure.

Shoe-heel Press′ing-ma-chine′. For pressing together the *lifts* which compose a boot or shoe heel, and dispensing with the shop work of hammer and lapstone. The bed is adjusted vertically by a screw to any thickness to which the blank heel may be built, and the plunger brought down by the depression of the treadle with such force as to compact the lifts together.

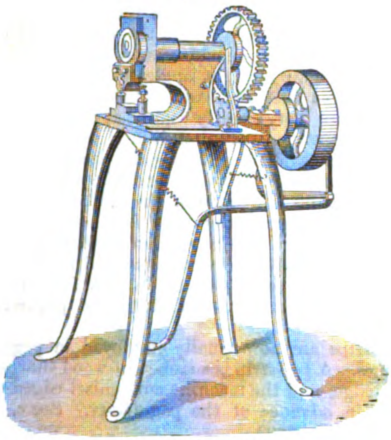
Fig. 5018.



Heel-Pressing Machine.

Shoe-heel Prick′ing-ma-chine′. The operation of this machine succeeds that of the heel-pressing machine. The compressed lifts, secured together in heel form by tacking, are placed upon the platen and pierced with all the

Fig. 5019.

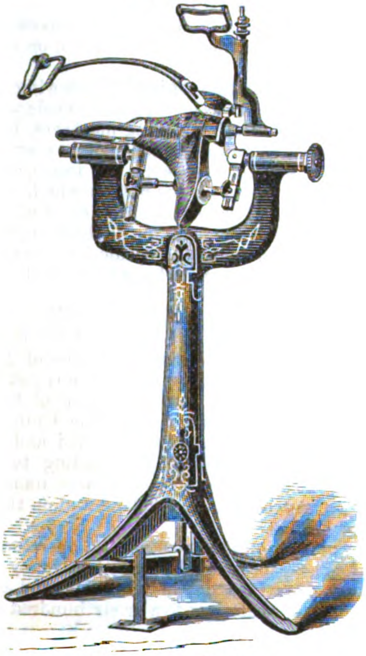


Heel Pricking-Machine.

nail-holes simultaneously, by the descent of the plunger carrying the gang of awls. The heel is then ready to receive the nails for attachment to the shoe.

Shoe-heel Trim′mer. The Coté heel-trimmer was patented in the United States in 1873, but first introduced into use in the Dominion of Canada. The shoe is held stationary by the treadle-clamp, and the knife-stock, which is centrally pivoted to the outer plate or jaw bearing upon the tread-lift, is then

Fig. 5020.



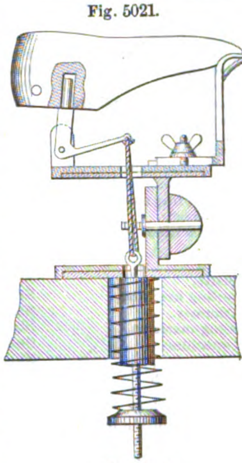
Coté Shoe-Heel Trimmer.

grasped in the hands of the operator, and moved to give a sweeping cut to trim the heel.

Shoe′ing-ham′mer. (*Farriery.*) A light hand-hammer used for shoeing horses.

Shoe′ing-horn. A device to assist in putting on a shoe. It is inserted between the heel of the person and the rear part of the counter of the shoe. Frequently made of polished horn, but also of sheet-metal.

Fig. 5021.



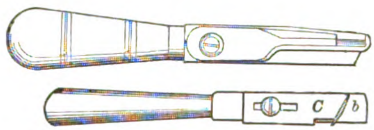
Shoe-Jack.

Shoe-jack. A holder for a last while a shoe is in process of manufacture. See Figs. 5017, 5020; PEGGING-MACHINE, Figs. 3603 and 3606. In the example, by horizontal and vertical adjustments, which incline it as required, the last is presented in a convenient position for stitching or pegging the work.

Shoe-key. (*Shoemaking.*) A hook by which a last is withdrawn from a boot or shoe.

Shoe-knife. A thin blade of steel affixed by a tang in a wooden handle, and used by shoemakers for cutting and paring leather. One shown in Fig.

Fig. 5022.



Guarded Shoe-Knife.

5022 is provided with a gage or guard *C* having a turned-up lip *b*, and adjustable by means of a slot and thumbscrew to determine the depth of cut.

Shoe′mak-er's Pinch′ers. The jaw-tool with which a shoemaker strains the leather over the last. See *L S*, Fig. 3726, page 1706.

Shoe′mak-ing-ma-chine′. Mark Isambard Brunel obtained an English patent, August 2, 1810, No. 3369, for a machine making boots and shoes. It was intended for fastening the soles to the upper by metallic pins or nails. It shows a press with clamping plates the shape of the sole, between which the leather is pressed, their margins forming the guide for a knife which cuts them to form. The sole is then clamped on a last, and a plunger with an awl and punch at the end is brought down by a lever. The pegs of "metal, leather, bone, whalebone, catgut, or any other animal or vegetable substance fit for it," are placed by hand in the holes made by the awl. As each one is driven the awl on the plunger makes a hole for the next peg. The peg-holes are spaced by notches on the guide-plate, which is clamped on the shoe-sole, and exposes a half-inch margin of sole all round. Metallic pins are clinched; others are beaten and seared.

The modern practice is to divide the various operations among a number of machines, which are separately considered on the adjacent pages.

Shoe-nail'ing Ma-chine'. See NAILING-MACHINE, Figs. 3283, 3284, 3285, pages 1507, 1508.

Shoe-pack. A moccasin of tanned or tawed leather. See PAC.

Shoe-peg. (*Shoemaking.*) A small slip of wood used to fasten the upper to the sole, and the soles to each other. See Fig. 3568, page 1648.

Shoe-pegs are said to have been invented by Joseph Walker, of Massachusetts, about 1818.

They are made by machinery. The bark is peeled off the log, which is then sawed into slices across the grain, a little thicker than the length of a peg. The face of each block which is intended for the heads of the pegs is planed smooth.

The block is grooved by a machine in which a V-shaped cutting-tool reciprocates rapidly across the face of the block, which is advanced the thickness of a peg between each stroke of the cutter, by feed-rollers. After the block has been grooved one way, it is again grooved at right angles to the first grooves, the surfaces of the block on one side now presenting a regular succession of quadrangular pyramids, which are the points of the yet embryo pegs.

The splitting is done on machines by a vertically reciprocating knife, which drives into each groove in turn, as the block is fed beneath it, the object being not to split the pegs entirely apart, but to have them hang together at the heads. The blocks are fed to the splitting-knives by fluted rollers, the flutes of which fit the grooves in the blocks made by the grooving-machine. When the block has passed through the splitting-machine once, it is turned and fed through again at right angles to the direction in which it was first fed, and after this operation the pegs are very nearly split apart, but they still hang together somewhat like a bunch of split lucifer matches. After the second feeding, knotty and faulty parts are removed, and the block is forcibly thrown off the table of the splitting-machine on to the floor, and the pegs fall asunder. The pegs are then dried in a tumbler heated by steam-pipes, bleached with sulphur fumes till they assume a uniform white color, run through a fanning-mill to free them from dust, and finally packed for market.

Peg-strips are now usually employed in pegging-machines. A *peg*-strip is a ribbon of wood sharpened on one edge, and the machine cuts chisel-edged pegs from it in advance of the peg-driver. See *c*, Fig. 3598, and Fig. 3603.

The largest factory of shoe-pegs in this country is at Burlington, Vt., where one factory transforms every day four cords of wood into four hundred bushels of shoe-pegs.

There are now many substitutes for wooden pegs; the cable screw-wire, pegs of pressed leather, rivets of various kinds. See Fig. 3598.

Shoe-peg machinery includes the *slabber* or *siding-machine*, for fitting the bearing surface of logs preparatory to sawing; sawing or *heading* machine; *boring*-machine for cutting out knots; *pointer*; *splitter*; *bleaching*-apparatus; *fan-blower*; *steam-dryer*; *polisher*; *separator*; *winnower*, or *duster*.

Shoe-pock'et. (*Ménage.*) A small leather pocket attached to a saddle for the purpose of carrying one or more extra horseshoes when on a journey on horseback.

Shoe-sew'ing Ma-chine'. The sewing-machine for boots and shoes was for some time made somewhat as the ordinary leather sewing-machines, but these did not reach the inside of the shoe in a satisfactory manner to sew the upper to the insole, although stitches could be put on the outside which sewed the soles together. The sewing-machine in which a device at the end of the jack, inside the shoe, was made to act in concert with the needle, piercing the sole from the outside, seems to have fulfilled the requirements of the case.

The machine of the McKay Sewing-Machine Association, shown in Plate LX., is the result of more than three years' effort and an expense of $130,000 before a practical working machine was put in operation (in 1861). The number of pairs of boots and shoes sewed on the machine in the United States up to the present time is two hundred and twenty-five millions (225,000,000), according to reports made by the manufacturers. A large number have also been sewed on it in England and on the Continent of Europe.

One or two of the most skillful operators on the machine have occasionally sewed as many as nine hundred pairs in a day of ten hours, and any good operator can easily sew five or six hundred pairs in a day.

In preparing a shoe for this machine, an inner sole is placed on a last; the upper is then lasted and secured to the inner sole, and the outer sole is then tacked on. This outer sole is channeled for the reception of the enchained part of the stitch. A large spool attached to the rotating horn is provided with thread coated with shoemaker's wax, and the thread, which passes from such spool about guides in the horn, to a whirl at the tip of the horn, is heated to warm the wax by a lamp carried on the horn. The whirl is a small ring placed at the end of the horn, and through which there is an opening for the pas-

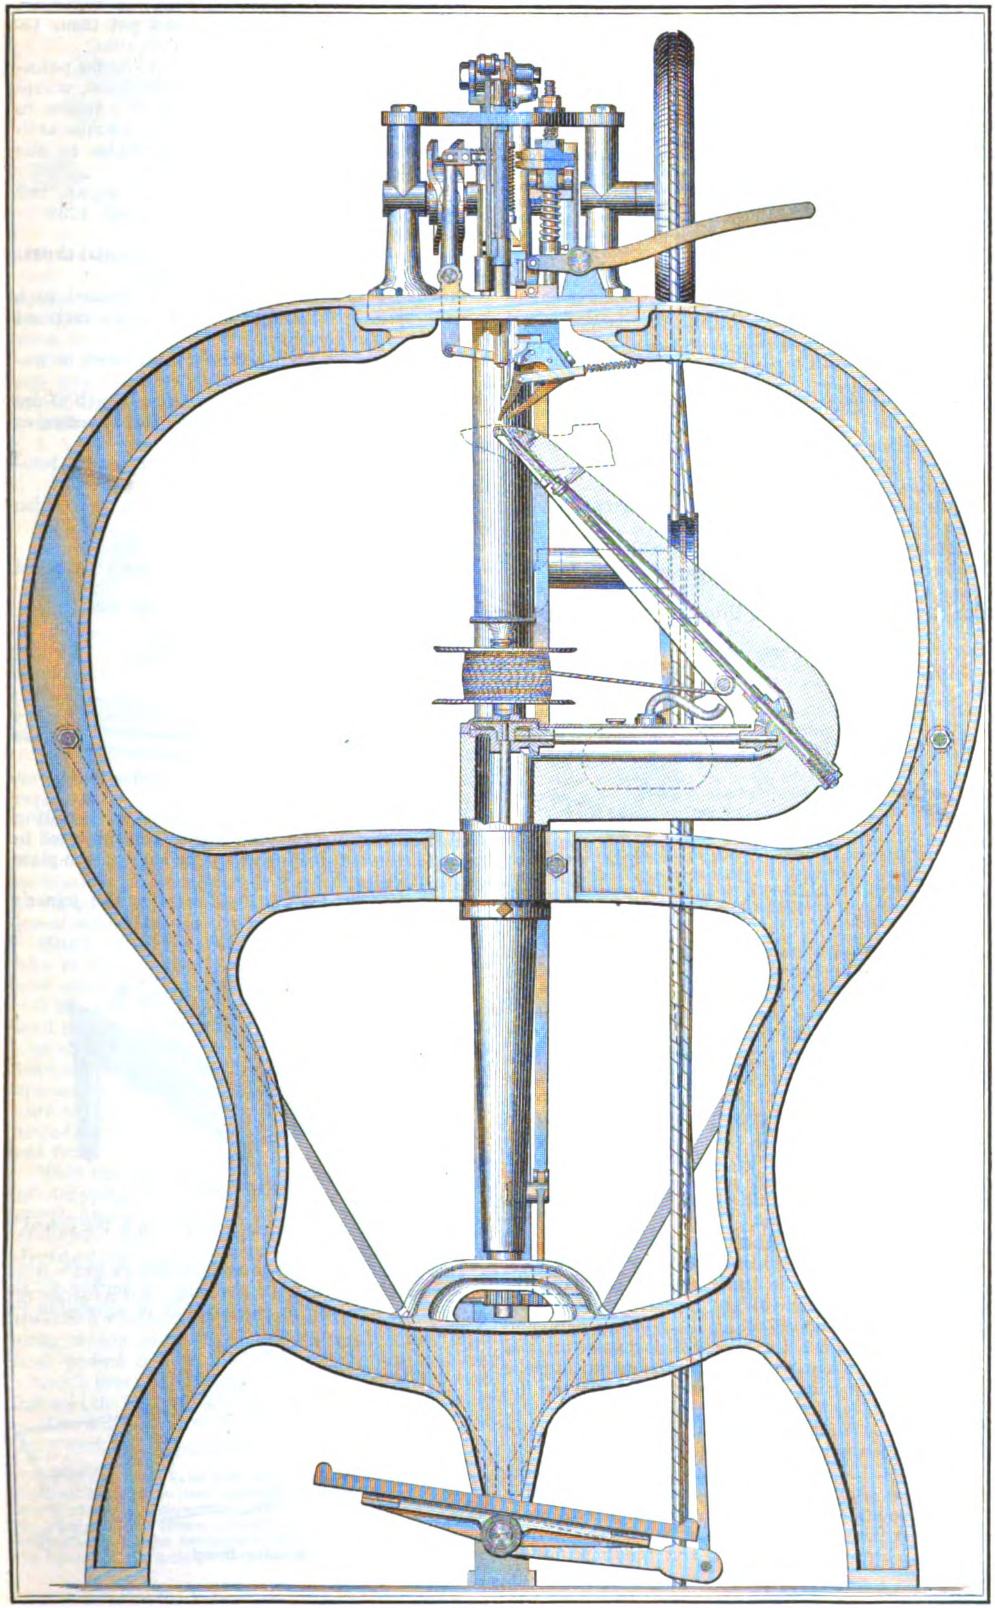

Plate LX. McKAY SHOE-SEWING MACHINE. See page 2162.

sage of the needle. A shoe is placed on the horn, as shown in dotted lines, and the stitching is commenced preferably at or near the shank, and as the stitching proceeds, the horn is rotated and the shoe moved thereon so as to bring it properly under the action of the needle. The hooked needle, after penetrating the sole resting on the horn, has the waxed thread laid in its hook by means of the whirl, and in ascending it draws a loop of thread through the sole and upper. A cast-off closes the hook and prevents the escape of the loop, while the shoe is moved for a new stitch, and when the needle next descends it passes through the loop on its shank and draws a new loop up through it, in this way enchaining one loop with another. Just enough thread is drawn from the spool to form a stitch, and this action is automatic, according to the thickness of the material being sewn.

Shoe-shave. (*Shoemaking.*) An implement on the principle of the spoke-shave, for trimming the soles of boots and shoes.

Fig. 5023.

Shoe-Shave.

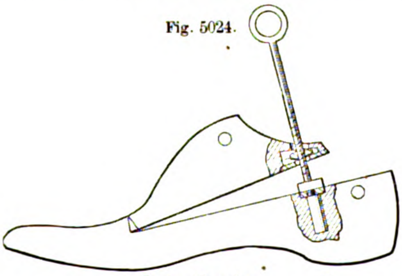
Shoe-sole. See Sole.

Shoe-stir′rup. (*Saddlery.*) A stirrup having a foot-rest shaped like a shoe.

Shoe-stone. A whetstone for a shoe-knife.

Shoe-stretch′er. An expansible last for distending shoes. The example shows one for stretching the instep. The nut, through which the operating screw passes, plays freely in the recess of the last block. The block may be elevated by a short screw taking into a nut in the last, or by a long screw resting upon a bearing screwed into said nut.

Fig. 5024.



Instep-Stretcher.

Shoe-valve. (*Hydraulics.*) A valve at the foot of a pump-stock, or at the bottom of a reservoir. In the figure it is shown as attached to a reservoir; the lever is moved by a rod which passes upward through a tube reaching to the water level. The screw-socket of the tube is shown on the right.

Fig. 5025.

Shoe-Valve.

Sho′la. (*Fabric.*) A substance resembling Chinese rice-paper, manufactured in India from the cellular pith-like stems of the *Hedysarum lagenarium*, and used for making life-buoys, boxes, bottle-cases, hats, and numerous other articles. Its cellular structure and lightness particularly adapt it for the manufacture of hats, and the ivory-like surface which may be imparted to it, for ornamental objects.

Shole. (*Shipbuilding.*) A piece of plank put under a shore where there is no ground-way.

Shook. 1. (*Coopering.*) A package containing the staves and heading of a cask ready for setting up. The materials for a cask are thus placed, ready prepared, in a compact form for transportation. Whalers carry out the staves and headings for oil-casks ready prepared in *shooks*, and put them together on board as the catch of fish requires.

Casks are also shipped in *shooks* to Africa for palm-oil and to other parts for other commodities, where the inhabitants lack the ability or the means to make their own packages. They form a staple article of exportation from the United States to the West Indies.

2. Furniture made in parts and not set up, but shipped in packs. See Knock-down, page 1239.

3. A set of boards for a box.

Shoot. 1. (*Architecture.*) The horizontal thrust of an arch or vault upon the abutments.

2. (*Hydraulics.*) *a.* A channel in a river forming a cut-off or an inclined plane for logs.

b. A branch from a main trunk or water-pipe.

3. (*Mining.*) A vein or branch of ore running in the same general direction as the *lode*.

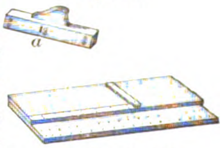
4. A trough or inclined plane to carry coal, lumber, or what not. A *chute.*

5. (*Weaving.*) The *weft* thread of a *web.* Also called the *woof, filling,* or *tram.*

Shoot-board. See Shooting-board.

Shoot′ing-board. 1. (*Stereotyping.*) A board or planed metallic slab with a plane-race on which an object is held while its edge is squared or reduced by a side-plane. It is used by carpenters and joiners, but the form shown in Fig. 5026 is especially adapted to the uses of the stereotyper in trimming the edges of stereotype-plates. The plate is held by the left hand upon the upper bench, resting against the bar. The side-plane *a* is reciprocated in the race, the bit shaving away the edge of the plate presented to it.

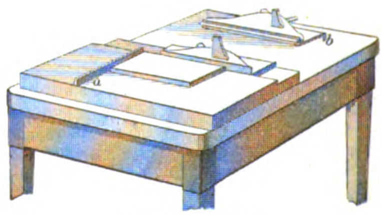
Fig. 5026.



Shooting-Board.

2. (*Joinery.*) Fig. 5027 illustrates the joiner's shooting-board mounted on a table. *a* is the board; *b*, the side-plane.

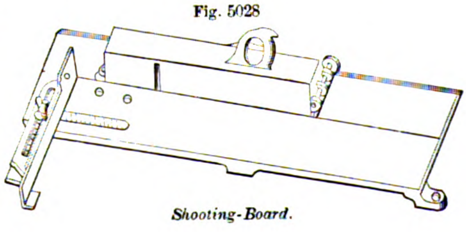
Fig. 5027.



Shooting-Board.

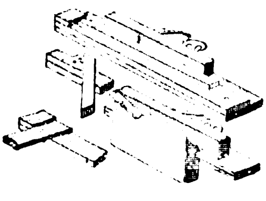
In Fig. 5028, the plane reciprocates on ways, and is adjustable to or from the edge or surface to be acted upon; a stop or holder that is adjustable to

Fig. 5028



Shooting-Board.

Fig. 5029



Shooting-Plane.

or from the plane, as well as at any angle, is also attached to the table.

Shoot'ing-plane. A side-plane used, in connection with the shooting-board, for squaring or beveling the edges of stuff.

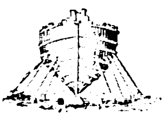
Shoot'ing-stick. (*Printing.*) A piece of wood or metal, usually about 1 foot long, 1½ inches wide, and ½ inch thick, by which the *quoins* are driven in *locking up* the *form* in the *chase.*

The *form* lies on the *imposing-stone*, the *foot* and *side sticks* are against the pages, and the *quoins* are driven between the *sticks* and the frame of the *chase.*

Shore. A prop or supporter.

1. (*Shipwrighting.*) *a.* One of the wooden props by which the ribs or frame of a vessel is externally supported while building; or by which the vessel is laterally supported on the *stocks.*

Fig. 5030.



Shore.

b. A timber temporarily placed beneath a beam to afford additional support to the deck, when taking in the lower masts.

c. A strut used to support a mast in heaving down.

d. The cap-shore is a beam placed forward of a cap to support it.

A vessel is supported in a dock by *breast-shores.*

2. (*Building.*) A *dead-shore* is a temporary post beneath a wall to carry the superstructure during repairs.

Short-pile. (*Hydraulic Engineering.*) A stick of round timber from 6 to 9 inches in diameter, and from 6 to 12 feet long. Such are driven as closely as possible without causing the driving of one pile to raise the adjacent ones. They are used to compress and consolidate ground for foundations.

Shot. 1. (*Fire-arms.*) *a.* Small spherical pellets of lead or *shot metal*, used for shooting birds and other small game.

They were originally made by rolling an ingot of lead into a sheet of a thickness corresponding to the size of the shot to be made, then cutting the lead into cubes and placing the latter in a "tumbler"; the action of the leaden cubes when rubbed against each other in the operation of the apparatus gradually rounding them until brought to a more or less spherical form.

This was superseded by the method now employed of dropping the molten metal, in a finely divided state, from a hight into water, invented by Watts, of Bristol, England, about 1782. It is said that he dreamed one night that he was out in a shower of rain, every drop of which was a round pellet of lead. Musing on the matter, he became interested in the question whether such would be the result of dropping melted lead. He accordingly melted some lead, and poured it from the top of St. Mary Redcliffe Church into water below. His plan succeeded, and he sold the invention for a handsome sum of money.

The following direction for making shot is found in a work published in the seventeenth century: —

"Melt lead down in an iron kettle, skim it, and when it is so hot that it begins to turn greenish, strew as much fine powdered auripigmentum (arsenic) upon it as will lie upon a shilling to every twelve or fifteen pounds of lead, which then must be stirred well, and the auripigmentum will flame. A little may be taken out in a ladle for an essay, and which, when reduced to a proper heat, may be dropped into a glass of water. If the drops prove round and without tails, there is auripigmentum enough therein, and the temper of the heat is as it should be; but, if otherwise, more auripigmentum must be added, and the heat augmented till it be found right."

Small shot is mentioned as hail-shot in many English statutes of the Tudors and Stuarts.

A shot-tower is usually about 180 feet high, and 30 in diameter at bottom, 15 at the upper story, where the melting is conducted in brick furnaces built against the wall around the central opening down which the melted lead is rained into a water-tank at the base of the tower. Platforms with furnaces are also built at lower elevations for making smaller sizes of shot. The method of reducing the lead to a shower of drops is either by pouring it into a sieve or by pouring it out of a wide ladle which has a serrated lip. The lead flows out in a number of streams, which break into separate drops, the resistance of the air and their cohesive tendency causing them to become spherical in falling.

Many of the drops, however, assume an elongated form, and sometimes two or more drops coalesce; these form imperfect shot, which are afterward separated.

The colanders or sieves are hollow hemispheres of sheet-iron about 10 inches in diameter, and the size of the holes is as follows for the respective sizes of shot: —

No. 0, the holes are 1/50 inch in diameter;
1, the holes are 1/55 inch in diameter;
2, the holes are 1/63 inch in diameter;
3, the holes are 1/72 inch in diameter;
4, the holes are 1/80 inch in diameter;
and by regular gradation to
No. 9, the holes are 1/380 inch in diameter.

The colander is faulty in respect of its delivering the stream at greater rapidity when full or nearly so, than when nearly empty, owing to the variation in pressure of the metal as it decreases in depth. It is now generally superseded by the ladle, which has a serrated side to divide the lead into streams equal in number to the serrations. Different ladles are used for varying sizes of shot, the serrations being more numerous for small shot and proportionately fewer for shot of larger size.

Fig. 5031.

Lead-Pouring Ladle.

The pourer takes a ladleful, perhaps 20 pounds of melted alloy, — for a little arsenic is added to the lead, — and resting it on a bar over the shaft, brings the lead into a quiescent state, scrapes away the oxide from the pouring side, and then carefully tips the ladle, so that the depth of the stream is even throughout the length of the comb, in order that the metal may be delivered in streams of equal sizes at the several notches. The drops having become partially cooled and consolidated during their fall, are received at the bottom of the tower in a *well* or reservoir filled with water, from whence they are taken and transferred to the drying-machine, where they are lightly rolled between flannel rollers, and when thoroughly dry the elongated and imperfect shot are separated by rolling the whole down a series of inclined planes, each slightly lower than the preceding and separated from it by a slight opening; the perfect ones, having a greater momentum leap the opening, while the defective ones fall through, and are remelted.

The different sizes are then separated by an apparatus resembling a chest of drawers, provided with sieves of different degrees of fineness, to which a shaking motion is imparted.

The shot are finally polished by placing them in revolving cylinders with graphite, by which, and the attrition, a black and shining surface is produced.

In 1849, a process of making shot by dropping the metal through a tube up which a strong current of cold air was driven was patented by Smith. This obviates the use of a high tower.

In 1868, Glasgow and Wood, of St. Louis, patented the making of shot by dropping the molten lead through a column of glycerine or oil, instead of air.

The sizes of drop shot vary with different manufacturers. The following gives the sizes and number of shot to an ounce, of a Baltimore and a New York house: —

Baltimore.				New York.

b. Projectiles for cannon are also generically termed shot. See CANNON-BALL; CASE-SHOT; GRAPE-SHOT, etc. See list under PROJECTILES.

Ordnance projectiles are, before being issued for service, subjected to a series of tests in order to ascertain if they are sound and of proper dimensions. The instruments required are one large and one small ring-gage, and one cylinder-gage for each caliber, a hammer, and steel punches. The shot or shell is first examined, to see that it has no flaws or other visible imperfections, and is then tried by passing it through the large ring-gage. It must pass through this in all directions, but must not pass at all through the small one. It is then tried by rolling it through the *cylinder-gage*, which is set up endwise at a moderate inclination. If it sticks, it is rejected.

In the case of a hollow projectile farther examination is required. It must be struck with a hammer, to judge by the sound if it be free from flaws or cracks.

The diameter of the interior cavity is then verified at various points by means of proper gages, as is also the diameter of the fuse-hole.

The shell is next placed in a tub of water, the fuse-hole being stopped with a wooden plug having an aperture for the insertion of a pair of bellows. The shell being nearly covered with water, air is forced into its interior by means of the bellows, and if there be any holes in it the air will rise in bubbles through the water. This test also gives another indication of the soundness of the metal, as the parts containing cavities will dry more slowly than the rest.

2. (*Mining.*) A charge of powder in a blast-hole, usually fired by a *smift* or slow-match.

3. (*Weaving.*) A pattern produced by weaving warp and weft threads of different colors.

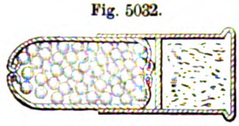
4. (*Nautical.*) Said of cables when two are spliced end on.

Shot-belt. A long leathern tube for shot, worn as a baldric, and having a charger at the lower end.

Shot-box. (*Nautical.*) A box in which grape or canister shot are placed convenient to the guns.

Shot-car′tridge. A round of ammunition for a shot-gun. The shot are frequently inclosed in a wire-gauze case to prevent their scattering too much. In the example, a fibrous, elastic tube is tied at one end, and prepared with stearine or similar substance, applied hot in a former; the small shot being inserted, the other end is tied. For breech-loaders, the cartridge is inserted into a copper capsule charged with powder and fulminate, in any usual manner.

Fig. 5032.



Shot-Cartridge.

Shot-gage. A metallic ring with a handle, used for testing cannon projectiles. Two sizes are employed for each caliber.

The *large* gage is slightly larger, and the *small* gage a little smaller, than the *true* diameter of the shot or shell, which must pass through the former but not through the latter. It is afterward rolled through a cylindrical gage, any jamming or sticking in which causes the rejection of the projectile.

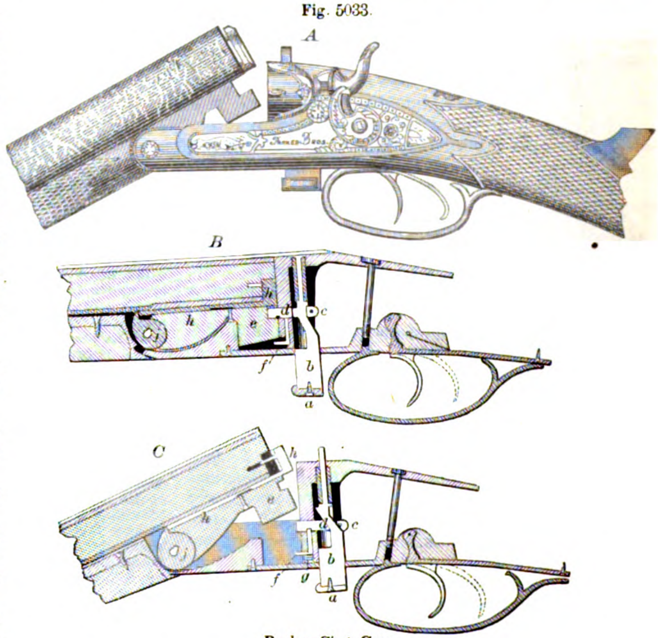
In the United States ordnance service the first are called *ring-gages*; the latter, *cylinder-gages*.

Shot-gar′land. (*Nautical.*) A wooden frame to contain cannon-balls, secured to the coamings and ledges around the hatchway of a vessel. See also SHOT-RACK.

Shot-gun. A smooth-bore fire-arm for shooting small game. Shot-guns are frequently made double-barreled, and of late years the breech-loading principle of Lefaucheux and others has been extensively introduced. Some breech-loaders, as Maynard's, are provided with interchangeable rifle and shot barrels.

Fig. 5033 is the Parker double-barrel, breech-loading gun, made by Messrs. Parker Brothers, West Meriden, Conn. *A C* show the barrels and mechanism in loading, and *B* in firing, position. For loading, the breech of the piece is placed under the right arm; by pressing on the finger-piece *a*, the lifter *b* is raised, and its beveled side, coming in contact with the screw *c*, draws the bolt *d* from a mortise in the lug *e*, releasing the barrels, which, turning on the joint *j*, are ready for the insertion of the cartridges. In this position, a small hole in the under side of the bolt comes directly over the trip *f*, which is thrown upward by the spiral spring *g*, and holds it against the lifter, whose top now projects above the frame directly in the line of sight of the gun. After inserting the cartridges, the barrels are brought down by a quick motion with sufficient force to bring the top of the barrel in line with the top of the breech-pin; the bottom of the lug *e* strikes the trip *f*, withdrawing it from the bolt *d*, which then enters the mortise in the lug; the cartridges, coming in contact with the face of the frame, are forced into the chambers, and the gun is ready for firing. As the action of the lifter not only withdraws the bolt from, but forces it into, the mortise of the lug, the fact of the top of the lifter being in place, so that the sportsman can sight along the barrel, affords an assurance that the gun is securely locked.

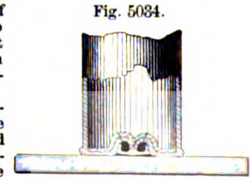
Fig. 5033.



Parker Shot-Gun.

An automatic extractor *h* inserted in a hole drilled in the lug and extending around and into the chambers of the barrels, serves to withdraw the cartridge-shells. Its front end rests against a snail on the joint *j*, on which the barrels turn; so that in assuming the position *A C*, it is forced backward, pushing out the shells sufficiently far to be readily withdrawn by the fingers.

Fig. 5034.



Cartridge.

The lock is of the rebounding class; the hammer being automatically thrown back to half-cock after firing by an arrangement which effectually prevents accidental discharge. See REBOUNDER.

Fig. 5035.

Capper.

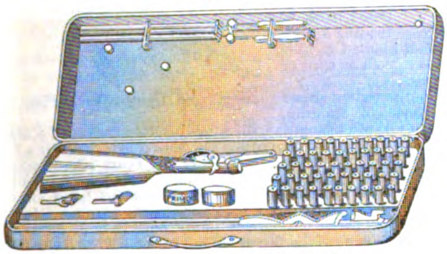
Fig. 5034 is the metallic shell used; it is made from one piece of metal, and reinforced by a *strengthener* soldered to its bottom; the Berdan primer is used in connection therewith, and is pressed home upon the nipple, so as not to project beyond the bottom of the shell, by the device (Fig. 5035).

A reversible loading plug is employed, either for charging the shells or withdrawing the caps.

Fig. 5036 shows the case containing the gun and its appurtenances complete.

Shot-lock′er. (*Nautical.*) Slats or planks pierced with holes to receive shot, and placed along the sides and round the hatchways.

Fig. 5036.



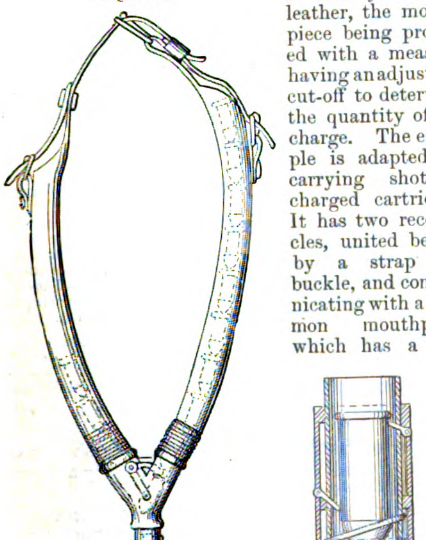
Parker Gun and Appliances in Case.

Shot-met′al. An alloy of lead, 56 parts; arsenic, 1. Used for making bird-shot.

Shot-plug. (*Nautical.*) A tapered cone of wood driven into a shot-hole in a vessel's side, to prevent leakage.

Shot-pouch. A receptacle for bird-shot, carried on the person. It is usually made of leather, the mouth-piece being provided with a measure, having an adjustable cut-off to determine the quantity of the charge. The example is adapted for carrying shot or charged cartridges. It has two receptacles, united behind by a strap and buckle, and communicating with a common mouthpiece, which has a gate permitting the escape of one cartridge at a time.

Fig. 5037.



Shot-Pouch.

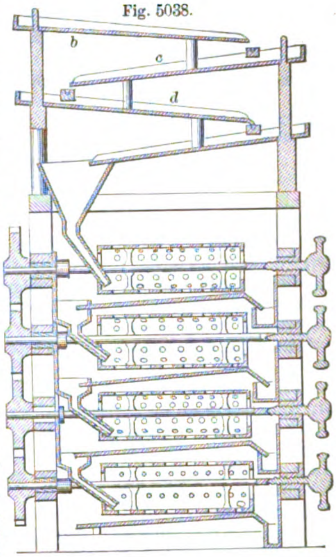
Shot-prop. (*Nautical.*) A wooden plug covered with tarred hemp, to stop a shot-hole in a ship's side.

Shot-rack. (*Nautical.*) A wooden frame, around a hatch or near a gun, in which a certain number of round shot are kept for service.

Shot-silk. (*Fabric.*) A silk stuff whose warp and weft threads are of two colors, so as to exhibit changeable tints under varying circumstances of light. *Changeable silk.*

Shot-sort′er. A frame with a series of sieves of different grades of fineness, to sort shot into various grades of size. The imperfect shot are separated by a series of inclines *b c d* with foot-troughs, over which the perfect shot are projected by their velocity, to be afterward assorted in a series of rotary screens of gradually increasing coarseness.

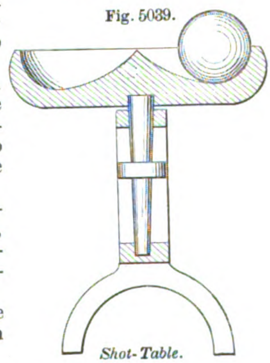
Fig. 5038.



Shot-Sorter.

Shot-ta′ble. A device for insuring the equal shrinkage of shot in all directions while cooling. It has an annularly grooved surface with a conoidal central projection, and turns on an upright spindle. The hollow spherical mold is placed thereon after the cast is made, and rotated until the casting is cool enough to be removed.

Fig. 5039.



Shot-Table.

Shot-tow′er. A tall building from the summit of which melted lead is dropped into a cistern of water. See Shot.

Shoul′der. A projection on an object, to oppose or limit motion or form an abutment, as

1. (*Vehicle.*) The butting-ring on an axle.

2. (*Carpentry.*) The square end of an object at the point where the tenon commences; as of a spoke, the stile of a door, etc. See Tenon.

3. (*Printing.*) The projection at the top of the shank of a type beyond the face of the letter.

4. (*Fortification.*) The obtuse angle formed by the junction of the *face* and the *flank* of a bastion.

5. The contraction in a lamp-chimney just above the level of the wick in an *argand* or *flat-wick* lamp. It answers the purpose of the diaphragm ring of coal-oil lamps.

Fig. 5040.

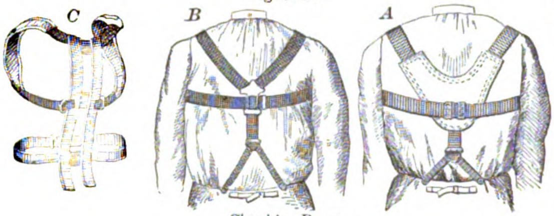
Shoulder-Block.

Shoul′der-block. (*Nautical.*) A single block having a projection at the bottom of the *shell* to prevent the rope that is rove through it from becoming jammed between the block and the yard. These blocks are

mostly used for *bumkin* or lift blocks on the lower yards.

Shoul'der-brace. (*Surgical.*) An appliance for treating round shoulders or unconfirmed curvatures of the spine. *A B* (Fig. 5041) illustrate two

Fig. 5041.



Shoulder-Brace.

forms, adapted to serve as suspenders or skirt-supporters, and used for preventing this deformity or in the treatment of its earlier stages. *C* is a brace with waist-belt and two steel back-pieces, employed in more advanced cases.

Shoul'der-ing-file. A flat safe-edged file whose narrower sides are parallel and inclined.

When made of large size and right and left, they are sometimes called parallel V-files.

Shoul'der-of-mut'ton Sail. (*Nautical.*) A triangular fore-and-aft sail, employed on boats, etc. The apex is at the head of the mast and the foot is extended by a boom.

Shoul'der-wash'er. (*Vehicle.*) The washer between a wheel and the shoulder of an axle-tree. The exterior washer is the *linch*-washer.

Shove. The central, woody portion of the stem of flax. The *boon.*

Shov'el. An implement having a hollowed blade and provided with a handle; used for raising earth or other material.

The mechanical character of a shovel consists in its adaptation for lifting and throwing loose matter. This is bringing it within closer bounds than is common in some parts of the United States, but the practice is a little loose. The term *shovel-plow* will remain in despite of anything that may be said as to the appropriateness of the name. The shape of the share was originally so nearly like that of a common pointed shovel that it has given a name to the tool. An excellent tool it is, either with one or two shovels, especially the latter. *Shares* they should be called, as their office is like that of plowshares.

The long-handled shovel with a curved, pointed blade, and a bent handle, is a Flemish tool, and a very good one.

The Flemish is heart-shaped, and has no *tread.*

The handle of the foundry-shovel is short. The blade should be of the best quality, and but slightly curved, to facilitate scattering the sand when mixing, or *turning it over* after casting.

Mining-shovels are shown at Fig. 3178, page 1451.

Bezaleel of Judah was a master mechanic, and made the shovels for the Tabernacle, 1491 B. C.; and Hiram, the widow's son of Naphtali, whose father was a man of Tyre, made the shovels for Solomon's temple, 1005 B. C. They were of brass, or rather bronze, as the copper was alloyed with tin, not zinc.

From their connection in the text with pots and tongs, they were no doubt fire-shovels. The tongs were of gold.

The wooden shovel (*palas ligneas*) was much used in Roman agriculture. Used in throwing up grain; as a winnowing-shovel it was termed *ventilabrum.*

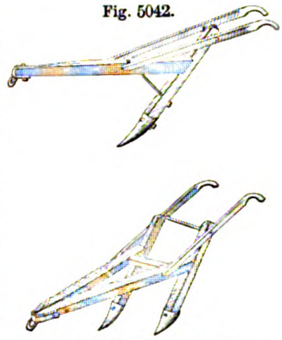
Hawkins's feeding-shovel, English patent, 1816, was for supplying coal to the bottom of a fire. It had a close cover, so as to form a box, and the handle was a sliding rod connected with a piston, by pressing which the coals were thrust into the fire.

Shov'el-plow. One having a simple triangular share, and employed for cultivating ground between growing crops.

The *shovel* is a *share*, but while objecting to the name there is no objection to the tool. They are made either single or double; so called, not that the *double-shovel* plow has, in any sense, a double shovel, but it has two sheths, and a share on each.

The *single*-shovel plow has been in use for many years; the double-shovel is a later invention. It resembles some of the plows used for a thousand years and more in Asia and Southern Europe (see *a b*, Fig. 3822, page 1743); but it is a better implement, and the double-shovel is nearly perfect in its way and for its purpose: that is, tending a crop which is planted in hills or rows, such as corn or potatoes.

Fig. 5042.

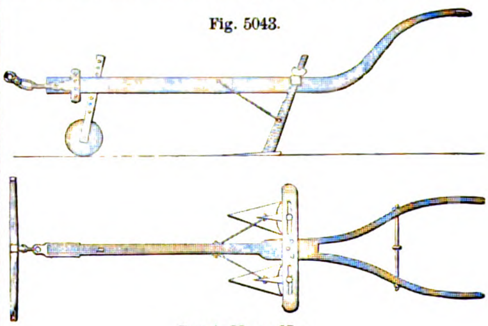


Single and Double Shovel-Plow.

The illustration shows the mode of framing. The shovels are triangular, the wings bending backward a little, and the point curved forward. The shovel is secured by a bolt to the sheth. A clevis on the nose of the beam affords means for attaching the single-tree of the horse. One plow is a foot in advance of the other; and it is a *right* or a *left* hand shovel-plow, according to the shovel which is in the advance. In the West farmers prefer left-handed plows, both in large plows and in shovel, throwing the furrow or soil to the left. In the Eastern States and in Europe the right-hand is said to be yet the favorite. Several reasons combine to make the left-hand the more convenient. Some refuse to try it. *Verbum sap.*

The nearest approach to our shovel-plow in Britain is the Scotch horse-hoe, which, when used without the middle shovel, has two shovels at the side, but parallel. This is inferior to the

Fig. 5043.



Scotch Horse-Hoe.

American oblique arrangement. The proper way to work all such tools is to go down one side of a row of plants and up the other side, using the forward shovel to work to the row, the other shovel merely cultivating the ground in the balk.

Show'er. (*Pyrotechny.*) A term applied to gold-rain, small stars of slowly burning composition, etc., constituting the decoration of a rocket or shell, and which produce the effect of a shower of fire in falling.

Show'er-bath. A bath in which a shower of water is dropped upon the person, usually a stream distributed by a strainer.

Shrap'nel. (*Ordnance.*) A hollow projectile for cannon, invented by General Shrapnel of the English artillery.

As originally constructed, the projectile consisted of an iron shell filled with balls, sufficient powder being mingled with the balls to burst the shell when the fuse ignited the charge.

It is also called *spherical case-shot*, and was designed to attain a longer range than common *case-shot* or *grape.*

The bursting charge is designed to be of just sufficient strength to open the shell without scattering the balls, which should continue their flight.

The *improved shrapnel* has its bursting charge in a cylinder in the middle of the shell.

The *diaphragm shrapnel* has its powder-chamber separated from the balls; the interstices between the latter being filled up with coal-dust.

Shrapnel are commonly filled with leaden musket-balls, melted sulphur or bituminous matter is poured in to fill up the interstices, and a chamber sufficiently large to contain the bursting charge is bored out beneath the fuse-hole.

Shrink'age. The contraction of a material in cooling after being heated; or in consequence of desiccation, as in the case of wood and clay. It is an important element to be taken into consideration in many mechanical processes.

1. (*Wood.*) The contraction of the fibers of wood is across the direction of their length.

In order to insure tight and true joints in wooden constructions, the wood should be perfectly seasoned before using. This, when effected in the natural way, which is best, requires from 1 or 2 to 10 years, according to the size and character of the piece.

2. (*Civil Engineering.*)

The volume of earth and sand in the natural bank exceeds that in embankment in the following proportions: sand, 1/7; clay, 1/9; gravel, 1/11; and the volume of rock in embankment quarried in large fragments exceeds that in bank fully one half.

The following diminutions in bulk occur when the loose material finally becomes compacted: light sandy earth, 1/8: yellow clayey earth, 1/10; gravelly earth, 1/12. — ELWOOD MORRIS.

Sand, 8 per cent; loam, 12 per cent; clay, 10 per cent; surface soil, 15 per cent; clay puddled, 25 per cent. — *New York Public Works.*

The following permanently occupy more space: hard sandstone, large fragments, 5/12; blue slate rock, small fragments, 6/10. — E. MORRIS.

Rock, one third to one half. — *New York Public Works.*

3. (*Metal-working.*) Molten metals, with the exception of some alloys, contract in cooling.

Patterns are always made larger in all their dimensions than the finished castings are required to be. For cast-iron about 1/96 is allowed, or 1/8 inch in every foot. Brass contracts rather more, 3/16 inch shrinkage to the foot being allowed. See CONTRACTION RULE.

The following table shows the actual shrinkage of various materials: —

Iron, small cylinders	= 1/16 inch per foot.
Iron pipes	= 1/8 inch per foot.
Iron girders, beams, etc.	= 1/8 in 15 inches.
Iron, large cylinders, the contraction of diameter at top	= 1/16 per foot.
Iron, ditto at bottom	= 1/12 per foot.
Iron, ditto in length	= 1/8 in 16 inches.
Brass, thin	= 1/8 in 9 inches.
Brass, thick	= 1/8 in 10 inches.
Zinc	= 5/16 in a foot.
Lead	= 5/16 in a foot.
Copper	= 3/16 in a foot.
Bismuth	= 5/32 in a foot.

This property is taken advantage of in the process of *shrinking on*, as it is termed, that is, surrounding a metallic cylinder with a ring, into which it will not enter while the ring is cold, but which slips on readily when it is heated to or below a red heat, and binds the cylinder firmly when cool: this is adopted for reinforces of some cannon, the couplings of propeller-shafts, the tires of car and carriage wheels, etc.

Shrink'ing-head. (*Founding.*) A body of molten metal in the gate of a mold, to supply metal to the casting during shrinking. A *riser.* A *sinking-head.*

Shroud. Plural, *shrouds.* 1. (*Nautical.*) *a.* Large ropes extending from the lower-mast heads to the sides of the ship, where they are fastened to the dead-eyes, which are secured to the channels. They serve to steady the mast athwartship, assist the stays and backstays in supporting it in a fore-and-aft direction, and afford means of ascending it.

The shrouds of topmasts are similarly secured to dead-eyes on the edges of the tops. Those of topgallant-masts pass over the ends of the cross-trees on the topmast-heads.

In each case the mast is supported laterally by the shrouds. The back stays are also auxiliary in this lateral support.

The *bowsprit-shrouds* extend from the head of the bowsprit to the sides of the vessel. The *futtock-shrouds* connect the topmast-shrouds around the edge of the top with the lower rigging at the cat-harpings.

Bentick-shrouds are ropes of the size of the topmast rigging, seized on to the *futtock-staves* and leading to the opposite channels, where they are set up to support the masts in heavy rolling.

Bumkin shrouds or braces; strong ropes fixed to the bumkin ends to support them in opposition to the purchase which acts on them in a contrary direction, to prevent them from rising and being sprung.

Shrouds are named from their position, or from the spar to which they are attached, as *fore, main, mizzen, topmast, topgallant,* etc.

b. The chains by which the smoke-stack is braced, in steamers.

2. (*Machinery.*) One of the two annular plates at the periphery of a water-wheel, which form the ends of the buckets.

Shroud-bri'dle. (*Nautical.*) A kind of crowfoot fastened to the shrouds, to hold sheets, braces, etc.

Shroud'ed Gear. (*Machinery.*) Cog-gear in which the cogs are protected by a flange coming out even with the face of the wheel, so that the interdental spaces are in effect mortises in the face of the wheel.

Shroud'ing. (*Hydraulic Engineering.*) The annular peripheral plates of a water-wheel, forming the ends of the buckets; usually termed the *sides* of the buckets, as occupying positions at the sides of the wheel.

Shroud-laid Rope. (*Rope-making.*) A rope made of four strands twisted around a core. A *hawser-laid* rope is of three strands twisted together without a core. See ROPE.

Shroud-plate. 1. (*Nautical.*) *a.* An iron plate fixed to a ship's side for the attachment of the shrouds.

b. A ring surrounding a mast and to which the futtock-shrouds are secured.

2. (*Hydraulics.*) One of the annular plates of a water-wheel which form the ends of the buckets.

Shroud-truck. (*Nautical.*) A wooden thimble secured to the shrouds and acting as a fair-leader for the running-rigging.

Shrunk-on. (*Metal-working.*) A term applied to iron bands, tires, or reinforces, which are placed on an object while hot, so as to shrink tightly around the object in cooling.

Shuf'fle-scale. (*Tailoring.*) A measure used by tailors. It is graduated at both ends, each end being independently adjustable.

Shuf'fling-plates. (*Locksmithing.*) A series of isolated slabs or boards, made to advance in a given plane, then to drop down, return on a lower level beneath another set of advancing plates, and then rise to repeat the movement.

Shunt. 1. (*Railroading.*) An English term signifying to switch off a car or train from the main to a side track.

2. (*Ordnance.*) The transferrence of the studs on a projectile from the deeper to the shallower sides of the grooves of a gun in passing along the bore, so that it may leave the bore axially, as is effected in Armstrong's and some other systems of rifling.

3. (*Telegraphy.*) A wire connected across the terminals of a coil, so as to divert a portion of the current.

Shunt-gun. (*Ordnance.*) A rifled gun, having two sets of grooves, — one down which the studs on the ball are passed in loading; and another, not so deep, along which the studs pass in discharging, — the ball being shunted from one set to the other at the bottom of the bore.

Shut. (*Metal-working.*) The line of junction of two pieces of metal united by welding.

Shute. A CHUTE or SHOOT (which see).

Shut'ter. 1. (*Joinery.*) A framing hung upon hinges to the sash-frame of a window, and serving

to close out the light or spectators. There are *inside* and *outside* shutters. The former are usually in several pieces, called *flaps*, which are hinged together and fold into a casing called a *boxing*.

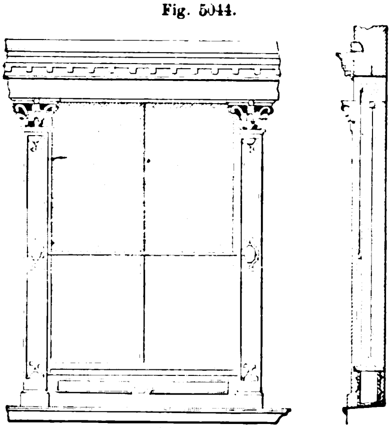
The principal piece is a *front shutter*, and the auxiliary leaf is a *back flap*.

A *flag-shutter* has but one leaf.

Some shutters are arranged to be opened and closed by a sliding movement, either horizontally or vertically; and others, particularly those for stores or shops, are made in sections so as to be entirely removed from the window.

Howards' wire shutter consists of a strong wire grating attached at each side to a band of spring-steel or brass kept in

Fig. 5044.



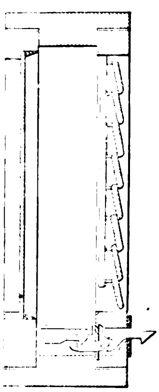
Wire Shutter.

place by a groove in the sash. The lower end is secured to a horizontal bar, and the upper to a roller, by which the shutter is raised or lowered, winding or unwinding.

2. (*Founding.*) A gate for cutting off the supply of metal to a mold. See SHUTTLE.

Shut'ter-fast'en-ing. A hook or catch for fastening a shutter; open or shut. The example has a catch for each position.

Fig. 5045.



Shutter-Fastening.

Shut'ter-hook. 1. A hook on a shutter, to fasten over a catch on the wall or window-sill.

2. A catch on the wall, to hold the shutter, which is opened against it.

Shut'ter-lift. A catch on a store-shutter, by which to lift it (*a b*, Fig. 5046).

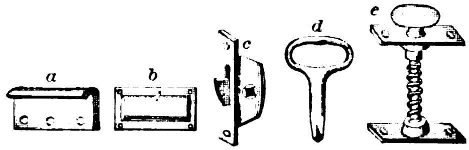
Shut'ter-lock. (*Carpentry.*) A mortise-lock in the edge of a shutter or door. *c*, shutter-lock; *d*, key.

Shut'ter-screw. (*Carpentry.*) A screw which passes through a shutter, from the inside of the store front or door, into a nut mortised into the shutter, and not exposed to the outside (*e*, Fig. 5046).

Shut'ting-post. The post or joint against which a gate or door is closed.

Shut'tle. 1. (*Weaving.*) A boat-shaped piece of wood which carries a *bobbin* or *cop*, containing the yarn of the *weft* or *woof*. The shuttle sometimes has wheels to facilitate its motion. It is

Fig. 5046.



a b, Shutter-Lifts; c d, Shutter-Locks; e, Shutter-Screw.

thrown by hand or by the fly. In the latter case, the ends of the shuttle-race form boxes into which the shuttle is received, and out of which it is driven by a *picker*.

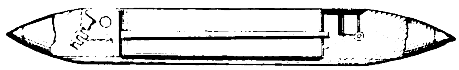
John Kay, of Bury, England, was the inventor of the fly-shuttle, 1735. This reduced the labor of weaving by one half, and raised it from the position it had occupied since the time the pyramids of Egypt were built. He, like many of his class, was driven from town to town, persecuted by the weavers who used his shuttle, died in poverty in Paris, and was buried in obscurity.

"My days are like a weaver's shuttle." — JOB.

The following show a few of the numerous varieties of loom-shuttles: —

Fig. 5047 has a spindle on a hinge. The bearing of the serpentine spring is so placed on the spindle-head as to hold the spindle up, when completely raised for the substitution of the

Fig. 5047.

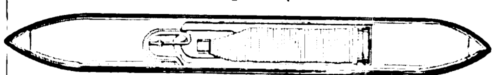


Loom-Shuttle.

bobbins; but when the spindle is slightly depressed the spring acts to return it to working position, and with accumulative force.

In Fig. 5048, the upright guide-wire placed within the cavity at the delivery end of the shuttle is so shaped as to assist the

Fig. 5048.

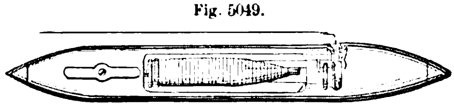


Weaver's Shuttle.

operator in guiding the thread to a narrow slit in the side of the shuttle, and thence to the eye.

In Fig. 5049, the devices are to regulate the tension of the filling as it runs from the spool to the eye of the shuttle. A spring-

Fig. 5049.

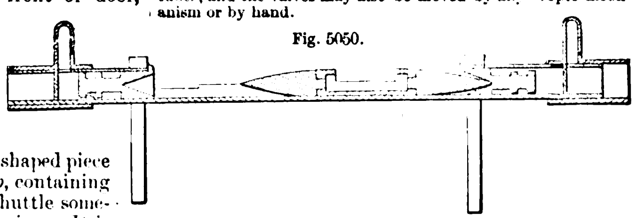


Tension Device for Shuttles

loop is placed on the inside, near the eye, in connection with a stationary wire by which the strain is equalized and the kinks straightened out. In threading, a curved wire hook is introduced through a guide-way cut in the shell of the shuttle, to catch the filling and draw it through the eye.

In Fig. 5050, the shuttle is thrown by pistons operated by condensed air. The race terminates at each end in a cylinder in which the piston plays. The air is introduced through flexible tubes, and the valves may also be moved by any proper mechanism or by hand.

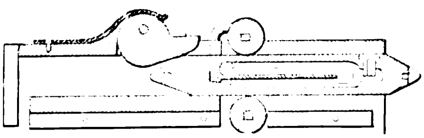
Fig. 5050.



Shuttle operated by Condensed Air.

In Fig. 5051, pickers are dispensed with, and the shuttle is driven by rapidly revolving frictional rollers, which intermittingly are brought into contact with its sides.

Fig 5051

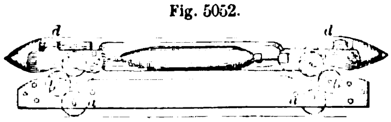


Roller-driven Shuttle.

An eccentric *swell* gradually checks the shuttle upon its being received by the shuttle-box, and instantly releases the same upon its expulsion.

In Lyall's loom the shuttle is carried through the shed on a carriage which moves on an iron raceway, and is carried back and forth by a band which receives an alternating longitudinal motion from a wheel. Upon this carriage is laid the shuttle which rests on the rollers *b b*. These rollers revolve because they are in contact with the rollers *a a*, which are in turn caused to rotate by the movement of the carriage on the raceway, and impart a precisely equal motion to the rollers *c c* of the shuttle. Hence, in passing over the lower threads of the shed, the shuttle produces no friction. The shuttle is held down by a projection above, against which the rollers *d d* play. The upper threads of the shed pass between this projection and the rollers *d d*. See POSITIVE-MOTION LOOM, Fig. 3903, page 1772.

Fig. 5052.



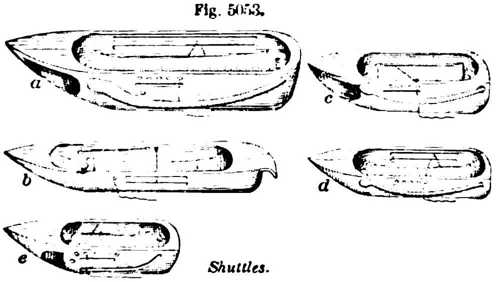
Positive-Motion Shuttle.

The *shuttle* for haircloth weaving has no *pirn*, but a spring-catch to hold the ends of the hair forming the *weft*, and carry them through the *shed* when the shuttle is thrown.

2. (*Sewing-machine.*) The sliding thread-holder which carries the lower thread between the needle and the upper thread, to make a lock-stitch. See SEWING-MACHINE.

Fig. 5053 illustrates different forms and relative sizes of shuttle employed in several lock-stitch sewing-machines.

Fig. 5053.

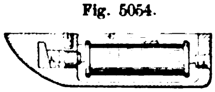


Shuttles.

a, Singer, for manufacturing purposes.
b, Howe, "C."
c, Singer, No. 5.
d, Singer family-machine.
e, another form of "Singer."

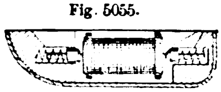
In Fig. 5054, a lever *c* is so bent and placed within the shuttle that one end bears upon the bobbin-thread, while its other end bears against a spiral spring, which presses a sliding bearing against the axis of the bobbin. The diminution of the thread relieves the pressure of the lever upon the spring.

Fig. 5054.



Shuttle.

Fig. 5055.

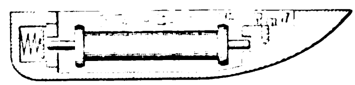


Shuttle.

Fig. 5055 has spring bearings for both journals of the bobbin.

In Fig. 5056, the thread tension is regulated by means of the free end of the spring *c* being locked in a notch of the adjustable cam *d*.

Fig. 5056.



Shuttle.

3. (*Hydraulic Engineering.*) The gate which opens to allow the water to flow on to a wheel. That side of a wheel which receives the water is known as the *shuttle* side.

4. (*Founding.*) When a casting is poured direct from the furnace, a kind of sluice, consisting of a sheet-iron blade covered with dried loam and provided with a long handle, is placed where the *sow* terminates and the ingate begins. By means of this, the molder only starts pouring when the sow is sufficiently full and the iron of the right temperature, and he controls the flow during the whole time.

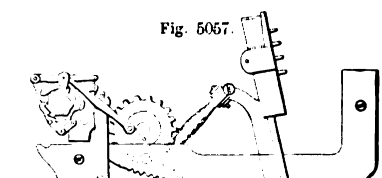
Shut'tle-bind'er. (*Weaving.*) A contrivance in a shuttle-box to catch the shuttle and prevent its bouncing out.

Shut'tle-box. A tray or case at the end of a shuttle-race, to receive the shuttle at the end of its fly.

Specifically, one of a set of compartments containing shuttles with differently colored threads, and brought into relation with the picker according to the pattern. The shuttle-boxes are adjusted vertically to bring the shuttles in the required succession to the pickers; a pattern-chain governs the movements of the rods to which the shuttle-boxes are secured.

In the example, a lever is connected by a link to a standard, upon which latter the shuttle-boxes are mounted, and is operated by two cams in such a manner as to raise or lower the standard upon which the series of shuttle-boxes is placed, so that any one of the boxes may be brought to the race from any position at every pick. The cams are actuated by a pawl and ratchet connected by rods with levers placed in contact with a revolving pattern-chain.

Fig. 5057.



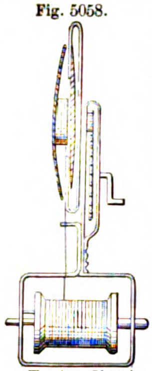
Shuttle-Box for Figure-Weaving Loom.

Shut'tle-check. (*Weaving.*) A device to prevent a shuttle from bouncing out of the box by recoil. It may be a simple binder, which grips the shuttle with sufficient force, or it may be a positive bar to the motion of the shuttle, operated by the stop motion.

Shut'tle-race. (*Weaving.*) The track on the lay on which the shuttle runs as it passes through the shed.

Shut'tle-wind'er. A device for winding a shuttle, such as the round shuttle of the Wheeler and

Fig. 5058.



Tatting Shuttle-Winder.

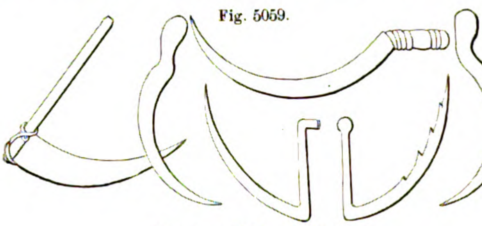
Wilson sewing-machine, or a tatting-shuttle, as in the example. The shuttle is attached to a clasp and rotated above the spool; the spring which serves to carry and revolve the shuttle also forces its jaws open to receive the thread. See also BOBBIN-WINDER, Figs. 755, 756, pages 317, 318.

Shwan-pan. The Chinese abacus. See ABACUS; SCHWAN-PAN.

Sick'le. (*Husbandry.*) A hooked blade, flattened in the plane of its curve and sharpened on its inner edge. One side of the blade is notched, so as always to sharpen with a serrated edge.

Fig. 5059 shows some patterns of sickles as used by the Egyptians, it may be said, from time immemorial; for the tombs of Beni-Hassan and Thebes show that it was used in the times of

Fig. 5059.



Egyptian Sickles (1500 B. C.).

Jacob and of Moses, an interval in which 70 persons and their servants became 3,000,000. The sickles are drawn from colored views in the tombs. In some, the blade is colored blue, to represent iron or steel; in others, it is colored to represent bronze, which was no doubt the metal more commonly used for this purpose; in fact, bronze was used even for surgical instruments down to A. D. 79, as is proved by the discovery of a complete set at Pompeii.

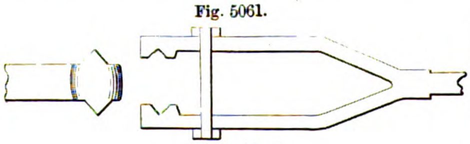
Fig. 5060.

Ancient Egyptian Reaping-Hook.

Fig. 5060 is copied from a painting in the Ancient Elethia, and indicates the shape and mode of using the sickle in Egypt. The handle was stocked at right angles to the sweep of the blade. This is not so convenient as our mode of handling, as it requires so firm a grasp to prevent rotation in the hand.

Sick'le-head. (*Husbandry.*) The pitman-head in a reaping-machine, which grasps the end of the cutter-bar. In the example, the sickle-bar head has

Fig. 5061.



Sickle-Head

conical points, which enter corresponding sockets in the forked arms of the pitman.

Side. 1. (*Machinery.*) The lateral portion of an object.

2. The surface on the *right* or *dressed* side of cloth.

3. (*Nautical.*) The part of a vessel from *stem* to *stern* and from the *gunwale* to the *main*-wale. Below the latter is the *bottom*.

Side-axe. An axe with a handle bent somewhat askew, to prevent striking the hand in hewing. A *broad-axe*.

Side-bars. 1. (*Saddlery.*) Two plates which unite the *pommel* and *cantle* of a saddle. In the Murdock saddle they are of steel, and give elasticity to the seat, which is suspended from the *pommel* and *cantle*.

2. (*Carriage.*) The longitudinal side-pieces of a traveling-forge or battery-wagon.

Side-beam Steam-en'gine. A form of *marine engine* invented by Napier of Glasgow. The original *beam-engine* was the *atmospheric engine* of Newcomen. The working-beam was elevated on a wall or pillar, the pump and piston-rods being attached to the respective ends. The extreme elevation of the beam and the want of compactness of the structure rendered desirable the change which Napier accomplished.

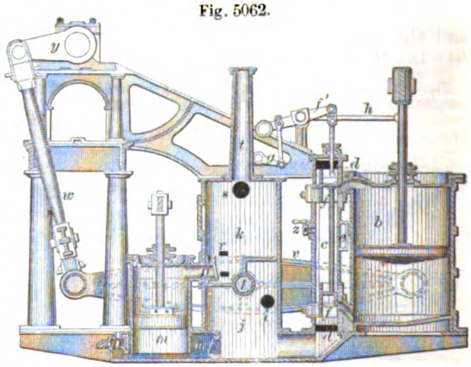
The lowering of the center of gravity increases the stability of the vessel, and, in some cases, the machinery is brought below the water-line, — an especial advantage in war-vessels.

The length of the stroke in marine engines is shorter in proportion to the diameter of the cylinder than is usual in land engines, and seldom much exceeds the diameter of the cylinder. Instead of a single beam, the center of which is elevated above the center of the shaft, two side-beams are used, working outside the side-frames, and having their centers as low down as the vibration of the beam will admit, the connecting-rod working upward instead of downward.

The shaft is considerably elevated above the top of the cylinder, and the frame is braced to the cylinder by a diagonal truss. The cold-water pump and cistern of land condensing-engines are dispensed with, injection water from overboard being freely used.

The illustration is a longitudinal section, and is taken from Hebert. *a* is the foundation plate on which the engine is erected; it is supported upon two deep sleepers of wood, which cross the floor timbers of the vessel, and to which they are firmly bolted. A portion of the bed-plate is formed into a channel, nearly as deep as the sleepers, and a part of this channel forms the bottom of the condenser, while another part receives the foot of the air-pump. *b* is the cylinder; *c* the slide-case, which is formed into three vertical compartments, connected at top and bottom by the apertures *d d*; the needle compart-

Fig. 5062.



Side-Beam Engine.

ment forms the steam-chamber, and the side compartments are the eduction-passages; *e* is the steam inlet; *f* the slide-valve, formed of two short slides, connected by a rod; the slides, which on the back form $1/3$ of a circle, are pressed up to the seats by screws at the back, acting upon a block of metal; f' is the valve-lever, working upon the shaft of the parallel motion as a fulcrum; the motion of the eccentric is communicated by the intermediate lever *g*; *h*, the parallel bar; *j*, the condenser, cast in one piece with *k*, the hot-well; *i*, the injection-pipe. A tube or cylindrical passage is cast in the condenser, through which pass the gudgeons *l* of the working-beams: these gudgeons are securely wedged into bosses cast on the sides of the condenser, and the brass bearings are fixed in a boss in the center of the beam. *m* is the air-pump; *n*, the foot-valve; *o*, the blow-through valve, through which the air and water are blown out of the condenser at starting the engine; *p*, the delivery-valve, through which the water passes into the hot-well; *r*, the connection with the relief-valve; *s*, the passage by which the waste water is carried into the sea; *t*, an air-vessel; *v*, the beam; *w*, the connecting-rod; *y*, the crank; *z*, the blow-through cock, connecting the

steam-chamber of the slide-chamber with the eduction-passage. This cock is opened before starting the engines, for the purpose of expelling air from the latter.

The feed-pump and bilge-pump are worked from the cross-head of the air-pump, and are not shown in the cut.

Side'board. 1. (*Carpentry.*) A vertical board at the side of a work-bench, and provided with holes or pins for supporting one end of a piece of work, the other being held by the bench screw or clamp.

2. (*Vehicle.*) An additional board on the side of a wagon, to increase its carrying capacity.

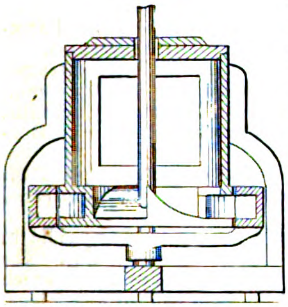
3. A piece of dining-room furniture with table and drawers.

Side-chain. (*Locomotive Engine.*) One of the chains uniting the sides of the tender and engine, as a safety arrangement in the event of the drag-bar giving way.

Side-cut'ting. (*Civil Engineering.*) Earth cut away on the side of a canal or railroad when there is not sufficient excavation on the line to form the embankments.

Side-dis-charge' Wa'ter-wheel. (*Hydraulics.*) A form of turbine in which the water, being received at the center, is discharged radially. In the example, the water falls vertically on central chutes, and is deflected outward and forward against the buckets, from which it has a side discharge.

Fig. 5063.



Side-Discharge Wheel.

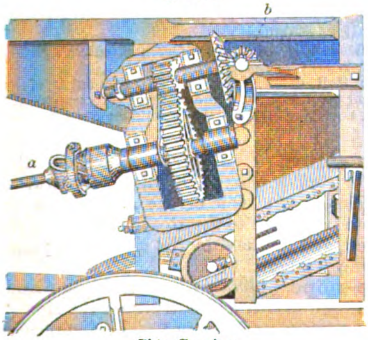
Side-drum. (*Music.*) A drum with a wooden body and somewhat longer than the ordinary drum; slung at the side of the performer. It gives a duller sound than the drum whose sides are of metal.

Side-fil'lis-ter. (*Joinery.*) A plane for making a rabbet. The width and depth is regulated by a movable stop. Much used in planing stuff for window-sash. See *h*, Fig. 3783, page 1724.

Side-flap. (*Saddlery.*) A piece of leather which hangs between the stirrup-strap and the skirting.

Side-gear'ing. The cog-wheels on the side of a thrashing-machine, receiving motion from the tumbling-rod *a*, which is driven by the horse-power, and communicating motion to the thrashing-cylinder, whose axis is shown at *b*.

Fig. 5064.

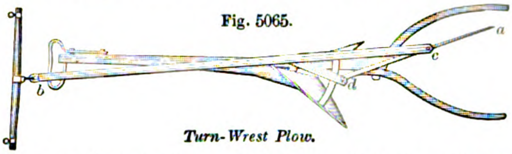


Side-Gearing.

Side-hill Plow. A plow whose cutting apparatus is reversible, so as to throw its furrow-slice to the right or left, as may be desired. This enables the lead horse of the team to return in the furrow just made, the plow throwing the soil down hill while traveling in either direction. This saves the time of going back empty with the ordinary plow when the hill is too steep to allow the furrow to be thrown up hill. It was originally invented by a Scotchman, a Mr. Gray, and was improved by Smith of Deanston and by Wilkie of Addington.

The English form of this plow has been in use for many years, being intended, as its name indicates, for plowing down hill with a back-and-forth furrow. It is called in England a *turn-wrest* plow.

Fig. 5065.



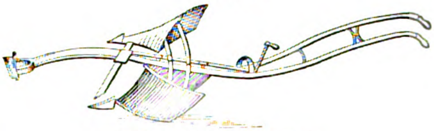
Turn-Wrest Plow.

"The beam, head, and sheath are placed in the direction of a line passing through their middle; and the two handles are placed equidistant on each side of that line. There are two mold-boards and two colters, and a mold-board is produced on either side at pleasure by moving the lever *a*, between the plow-handles, from one side to the other. The line of draft can be shifted with equal ease and expedition, and at the same time one of the colters raised up clear of the land, and placed along the side of the beam, whilst the other is put down and placed in a proper position for cutting off the furrow-slice from the land. These operations are performed by the plowman without changing his position between the stilts, by simply shifting two levers, *b c* and *d a*." — LOUDON.

Hay's *turn-wrest* (English) has a right-handed body and a left-handed one placed end to end, its beam and handles turning on a pivot at the center of the body. There are several United States patents of the same kind.

Huckvale's is so constructed that, by reversing the position of the handles, the body part is turned, and the sole becomes the landside, or *vice versa*; the share becoming the colter, or the colter the share, as the case may be.

Fig. 5066.



Wilkie's Turn-Wrest Plow.

Wilkie's *turn-wrest* plow (British) has two complete mold-boards and shares connected by bars to a rod, which form the axis on which they rotate when moved by an adjusting-rod between the handles. The same colter and landside answer for either the right or left hand plow. The rod extending to the colter, in moving the mold-board, moves also the colter one inch at the point, so as to give it the proper position in the line of draft. See also Fig. 2509, page 1103.

Fig. 5067.

Reversing-Movement.

The American form of the invention consists in making the share, mold-board, and landside upon a piece which moves on a horizontal axis at the lower edge. This is unlocked and partially rotated at the end of a furrow, converting the landside into a share and sole, and presenting the mold-board in the other direction.

Side-hook. (*Carpentry.*) A piece of wood having projections at the ends, used for holding a board fast while being operated on by the saw or plane.

Side-keel'son. (*Shipbuilding.*) An additional keelson on each side of and parallel to the main keelson, and secured to the floor timbers. Also called *sister keelson*.

Side-le'ver. (*Steam-engine.*) A heavy lever, working alongside the steam-cylinder and answering in its functions to the *working-beam*. The object is to economize hight and secure compactness (Fig. 5062).

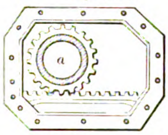
The *side-levers* communicate motion from the *cross-tail* to the side-rods, and they to the paddle-shaft.

Side-le′ver En′gine. (*Steam-engine.*) A marine engine having side-levers instead of a working-beam to turn the wheel-shaft. See SIDE-BEAM STEAM-ENGINE.

Side-light. (*Nautical.*) A plate of glass in a frame fitted to an air-port in a ship's side, to admit light. It is thrown open for ventilation, and closed when necessary to exclude water.

In Fig. 5068, *A*, the glass *a* is inclosed in a circular frame, having teeth gearing with a rack on the inside of a metallic box; it is rolled to one side to open the port, and is made water-tight, when closed, by an elastic packing in the frame.

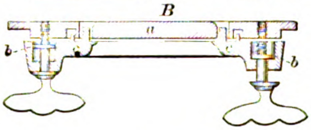
Fig. 5068.



A

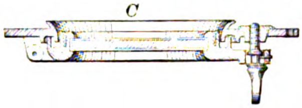
B. The light *a* is held in position by screws entering proper apertures in the vessel's side; the screws are provided with collars *b b*, which prevent them from falling out when the frame *c* inclosing the light is removed.

B



C. The light-frame *d* is hinged to the vessel's side, and is held when closed by a screw.

C

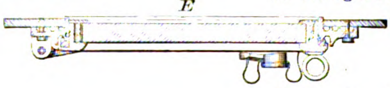


D. The frame is conical, fitting in an opening of corresponding shape, and is held in place by screws.

D

E. The face of the port-rim has one or more annular grooves *e e* corresponding to ridges on the light-frame, so fitting as to make a water-tight joint. It turns on a hinge, and is closed by a screw.

E



F

Side-Lights.

F. The frame turns on a hinge, and is held in closed position by a lever-catch *f*, having an interior screw by which the packing may be compressed as tightly as required.

Side-plane. (*Joinery.*) A plane whose bit is presented on the side, used to trim the edges of objects which are held upon a *shooting-board* while the plane traverses in a race. See SHOOTING-BOARD.

Side-plate. (*Saddlery.*) A wide leather trace-strap, which reaches back a little beyond the point at which it is connected to the breeching.

Side-pond. (*Hydraulic Engineering.*) A reservoir at the side of a canal-lock to economize the water in locking. A pond is placed on either side; each has the same horizontal area as the main chamber, is intended to contain one fourth of the *fill* of the latter, and connects with it by a sluice. The bottom of one pond is at half the hight or lift of the lock, so that when the valve is opened, it receives one quarter the contents of the main chamber; the sluice is then closed. The other chamber has its bottom at one quarter of the lift of the lock, and receives one quarter of the original contents of the main chamber. The lock is then discharged of the remaining one half and the boat floated in. To fill the lock, the contents of the *side-ponds* are discharged thereinto, which half fill the chamber, and save that amount from the upper level or pond. Thus half the amount is saved in locking up a canal-boat, which, passing up, finds the lock full, and allows a descending boat to be locked down with the expenditure of half a lockful of water. One lockful will carry a boat each way.

Side-rab′bet Plane. (*Joinery.*) A form of joiner's plane for working rabbets or sinkings on the sides of boards. The iron is vertical, and cuts at the side instead of at the bottom.

Side-rail. (*Railway Engineering.*) *a.* A short rail at a switch, to bear against the wheel-flange and keep the wheel on the track.

b. A hand-rail running alongside the boiler of a locomotive.

Si-de′re-al Clock. A clock regulated to keep regular time, *sidereal*, not *mean*. Sidereal time is reckoned by sidereal days of 23*h.* 56*m.* 4*s.* mean solar time, which are measured by the interval between two successive passages of any fixed star over the same meridian, and are divided into 24 sidereal hours.

Side-re-flect′or. (*Optics.*) A highly polished concave speculum placed at the side of an object, to direct an illuminating pencil of rays upon it.

Side-rib. (*Fire-arms.*) The rod at the side of a carbine to which the sling is fastened.

Side-rods. (*Steam-engine.*) Rods connecting the cross-head above the piston-rod with the side-levers of that form of marine steam-engine.

Sid′er-o-graph. (*Fine Arts.*) An engraving on steel. Specifically, the Perkins method. See BANK-NOTE ENGRAVING, page 228; TRANSFER-PRESS.

Sid′er-o-scope. An instrument for detecting minute degrees of magnetism by a delicate combination of magnetic needles. Invented by Lebaillif, and described by Brewster in his "Treatise on Magnetism."

Side-round. (*Joinery.*) A joiner's plane for making half-round moldings. They work in pairs, right and left.

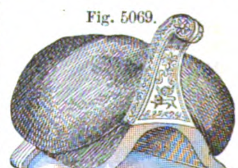
Side-sad′dle. (*Saddlery.*) A lady's saddle in which the feet are both presented on one side. The right knee is placed between the two horns, which are respectively called the *large* and the *small horn.*

Used by the Saxons in England; also in France, 1227. It was not very common, however. Riding like a man and on a pillion behind a man were the more usual practices till the seventeenth century; and even after that in places where the roads were too bad for wheeled vehicles.

The women in some parts of Europe still retain what we deem the masculine mode of riding.

The English ladies rode astride like men till the time of Richard II., when his Queen, Anne of Bohemia, introduced side-saddles (about 1380). Side-saddles had been occasionally used in some of the continental European countries for several centuries. What time the change was made does not seem to be known, but until 1540 ladies appear always to have ridden on the off side, whether on the side-saddle or pillion.

Fig. 5069.



Queen Elizabeth's Side-Saddle.

The side-saddle of Queen Elizabeth is still preserved at Horeham Hall, Essex, England. The pommel is of wrought-metal, and has been gilt. The seat is a velvet cushion.

"I did borrow a very fine side-saddle for my wife." — PEPYS, 1661.

Side-screw. 1. (*Joinery.*) A screw at the front edge of a work-bench, for holding the work.

2. (*Fire-arms.*) One of the screws by which the lockplate is secured to the stock. They pass through the stock, and are held by the side-screw plate or by side-screw washers.

Side-snipe. (*Joinery.*) A molding-plane made like a snipe's mouth and cutting on the side.

Side-space. (*Railway.*) The distance outside of each line of rails.

Side-stick. (*Printing.*) A tapering stick or bar at the side of a form in a chase. The matter is locked up by driving quoins between the stick and the chase.

Side-strap. (*Saddlery.*) A strap passing for-

ward from the breeching-rings, to unite with the tug at the back-band.

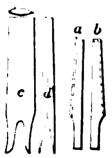
Side-tack'le. (*Gunnery.*) A purchase hooking in to an eye-bolt on a naval gun-carriage and an eye-bolt in the ship's side, and serving to train the gun to point forward or abaft the beam, and to run it out of the port. Each carriage has a side-tackle on each side.

Side-tool. (*Wood-turning.*) *a. Right-side* tool, cutting on the side and end. So beveled as to cut from the right hand to the left.

b, left-side tool, the reverse of the former.

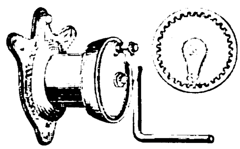
c d, for cutting insides of cylinders; sharp on the edge.

Fig. 5070.



Side-Tools.

Fig. 5071.



Side-Winch.

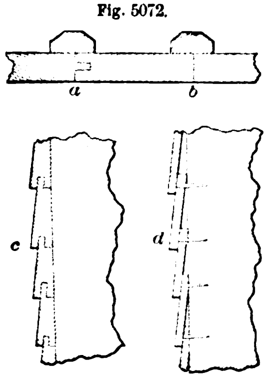
Side-tree. (*Shipwrighting.*) One of the principal or lower main pieces of a made mast.

Side'walk. A foot-pavement. A raised walk for pedestrians at the side of a road or street.

Side-winch. A hoisting device which may be secured to the side of a wall or a beam, for hoisting light weights. The motive apparatus is a crank whose shaft carries a pinion that meshes into an interior gear, to which the rope-carrying drum is attached.

Sid'ing. 1. (*Carpentry.*) The boarding of the sides of a frame building: it may be formed of boards nailed on flat with a plain butt-joint or tongued and grooved, the junction being covered with a cleat or strip (*a b*, Fig. 5072); the boards may be sawed beveling, and tongued and grooved (*c*), or plain weather-boarding (*d*) may be employed.

Fig. 5072.



Siding.

2. (*Shipbuilding.*) That part of the operation of *forming* or *trimming* ship's timbers, etc., which consists in giving them their correct breadths. It is one part of the operation of FORMING (which see).

3. (*Railway Engineering.*) A short line of additional track laid alongside of a railway, and connected therewith by switches. It is for a train to lie by while another is passing on the main line. A *turn-out, shunt*, or passing-place.

Sid'ing-ma-chine'. A machine for sawing timbers, or re-sawing boards into thin stuff for weather-boarding. See RE-SAWING MACHINE.

Siege. 1. The floor of a glass-furnace.

2. A workman's table or bench.

Siege-gun. (*Ordnance.*) A cannon sufficiently light to be conveniently transported, and throwing projectiles adapted for breeching walls in sieges. It is mounted on a siege-carriage, and forms part of the train of an army. The calibers employed in the United States service are the 18 and 24 pdr. smooth-bores and the 4½-inch rifled. A short 8-inch howitzer is also used for siege purposes. See CANNON.

Siege-gun Car'riage. (*Ordnance.*) Siege-gun carriages differ from those of ordinary field-pieces in being stronger and heavier, and in being destitute of the rings and hooks for carrying the implements. The limber has no ammunition-chest, the ammunition and implements being transported in wagons accompanying the train.

Three sizes of siege-gun carriages are used in the United States service: one for the 4½ rifled gun, model of 1861; one for the 18-pdr. smooth-bore gun, which also answers for the 30-pdr.; and one for the 24-pdr. Some peculiarities of construction and its mode of adaptation for transportation and service are described under GUN-CARRIAGE (which see).

Siege-train. (*Ordnance.*) The artillery, with its carriages and equipments, which is carried with an army for the purpose of attacking fortified places.

The guns are of sufficient caliber for breaching walls, but not too heavy for convenient transportation in the field. 18-pounder and 24-pounder smooth-bore guns, 8-inch howitzers, light 8-inch and 10-inch mortars, and, in the United States service, a rifled gun of 4½ inches caliber are employed. The gun-carriages are similar in general construction to those used for light artillery, and are unaccompanied by caissons. A peculiarly constructed wagon is employed for transporting the mortars. The ammunition and other supplies are carried in ordinary wagons, all of which are included in the general term *siege-train*.

Sieve. 1. A frame of wood or metal, having a meshed bottom, used for separating particles of different degrees of fineness.

The *sifter, strainer, riddle, colander*, are all forms of sieves, and have special applications rather than different functions.

The ancient Egyptian sieves were made of string, papyrus, or rushes, according to quality; and some were made of perforated metallic plates, as shown in a group where the public pounders are at work reducing to powder the materials brought to them. See MORTAR, Fig. 3226.

"The Gauls were the first to employ flour bolts made of horse-hair; the people of Spain made their sieves and meal-dressers of flax." — PLINY.

Sieves are of horse-hair, gauze, wire, silk (for pottery, porcelain, and flour), perforated parchment (for gunpowder), cloth, wooden slats, etc. See also SIFTER.

2. (*Founding.*) The hand-sieve is especially a molder's tool, in the use of which he becomes very expert. Brass-wire cloth of various degrees of fineness strained in circular hoops, three or four inches deep, is generally used.

3. A kind of coarse basket.

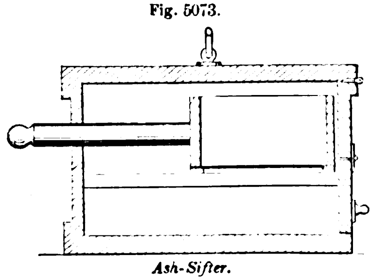
4. (*Calico-printing.*) A cloth extending over the vat which contains the color.

Sieve-cloth Loom. (*Weaving.*) A form of loom for weaving the fine goods known as bolting-cloth.

Sift'er. An implement with meshes, fine or coarse, according to circumstances, for separating materials according to size.

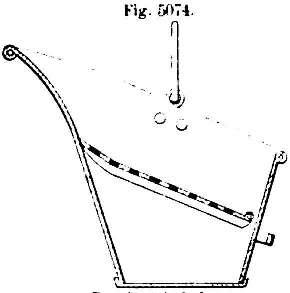
Sifters are used for sifting ashes from cinders; flour from lumps, etc.; sand from gravel; dust or smaller seeds from grain; and for various other purposes.

Fig. 5073.



Ash-Sifter.

Fig. 5074.



Scuttle Ash-Sifter.

Fig. 5073 is a reciprocating sifter for ashes; it is moved to and fro on slides in a box which confines the dust.

Fig. 5074 shows a hinged sifter in a coal-scuttle.

Fig. 5075 is a rotary ash-sifter.

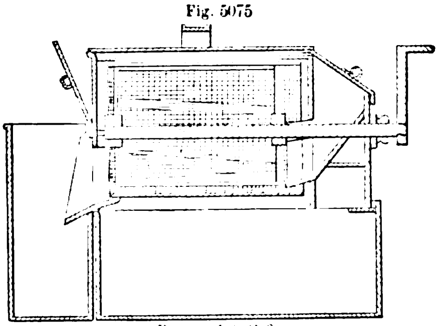
Fig. 389, page 169, shows an ash-sifter in a barrel.

Fig. 390, page 169, shows an ash-sifter in a deep stone hearth.

Fig. 388, page 169, is a rotary drum-sifter with a discharging trap.

Fig. 5076 is a scoop with a flour-sifter in the rear part.

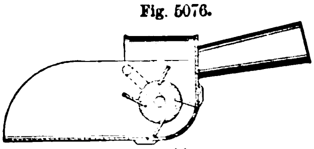
Fig. 5075



Rotary Ash-Sifter.

Fig. 5077 is a flour-sifter with a reciprocating scraper and a foraminous concave.

Fig. 5076.



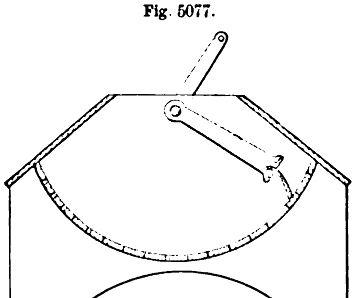
Flour-Sifter.

Fig. 5078 is a sand-sifter, having a series of sieves arranged with mechanism for imparting to it a rocking motion. The sand is raised by the cups of an elevator and discharged into the upper sieve.

Sift'ing-ma-chine'. See SIFTER; ASH-SIFTER; COAL-BREAKER.

Sight. 1. (*Ordnance.*) A piece of metal attached or applied to a fire-arm, and by which the

Fig. 5077.



Sifter.

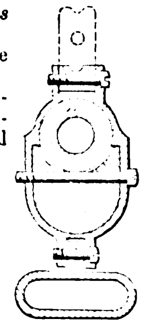
arm is pointed at the object. Small-arms have breech and front sights, the former usually notched and the latter pointed. See BREECH-SIGHT; LEAF-SIGHT; FRONT-SIGHT.

Sights for cannon include the breech-sight, front-sight, rimbase-sight, and PENDULUM-HAUSSE (which see). See BACK-SIGHT; MUZZLE-SIGHT; BREECH-SIGHT; TELESCOPIC SIGHT, etc.

The United States service rifle has a *notch* for 100 yards, and two *leaves* for 300 and 500 yards respectively.

Fig. 5079 shows a sight for service fire-arms.

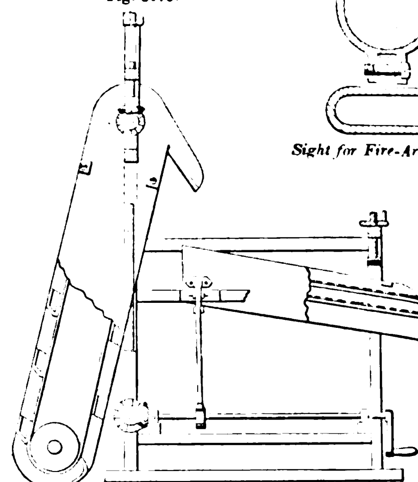
Fig. 5079.



Sight for Fire-Arms.

2. Some surveying and other instruments of precision have plain-sights, usually consisting of a vertical

Fig. 5078.



Sand-Sifting Machine.

piece with an opening divided by a spider's thread, hair, or fine wire.

3. (*Of a Drawing.*) The part within the border or margin lines. The *face* of the sheet consists of the *sight* and *margin*, the latter being the part outside of the border lines.

Sight'en-ing. (*Calico-printing.*) A fugitive color added to a paste to enable the printer to judge of the perfectness of the work.

Sig'nal. A means of communication by audible or visible signs between two distant points according to a preconcerted system.

The means of signaling are numerous. Among them may be cited: —

Balls.	Horns.
Bells.	Lanterns.
Bonfires.	Lights.
Electric sounders.	Rockets.
Flags.	Semaphores.
Guns.	Torpedoes.
Heliostats.	Whistles.

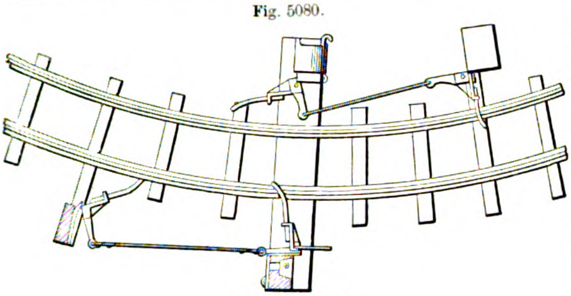
Flags are very generally employed for signaling, being equally well adapted for land or sea service. In the former case the various combinations are made by waving the flag to the right or left, or by holding it in a particular position. Nautical signals are formed by the different arrangements and combinations of several flags and pennants of different colors; each of these indicates a number, corresponding to a phrase or sentence, which is entered in a book. Every naval vessel is furnished with one of these books, by reference to which the number and signification of any combination displayed by another naval vessel of the same nation may be at once understood. The particular system used is termed a code. That of the British navy is capable of expressing about 14,000 words and phrases. Codes of more limited capability are employed in the merchant service.

Flashing-signals are made by intermittent flashes of lime light, of shorter or longer duration, so as to spell out a message.

Railway-signals are made for many purposes, usually to check speed or stop; but some signals indicate that the way is clear (see RAILWAY-SIGNAL). Fig. 5080 is a signal to be placed on curves, tunnels, or sidings. An adjustable hook on the cab of the locomotive strikes a trigger on a wayside post and sets a signal in advance.

Reconnoissances by signal-parties have been made by means of balloons on several occasions, the balloon in each case being

Fig. 5080.



Railway-Signal.

what is called *captive*, that is, being held by a rope to limit the ascension and prevent its escape.

The first occasion was at the battle of Fleurus, in 1794, when the French used it to ascertain the position and evolutions of the Austrians. It was fired at by the Austrians, but allowed to ascend out of range.

A captive balloon was again made use of by the French at Solferino, 1859.

A third use of balloons in this species of service was with the Army of the Potomac in the Peninsular campaign, and perhaps in other fields of action.

The search for the lamented Sir John Franklin gave rise to many ingenious schemes for signaling the party and giving them notice of succor.

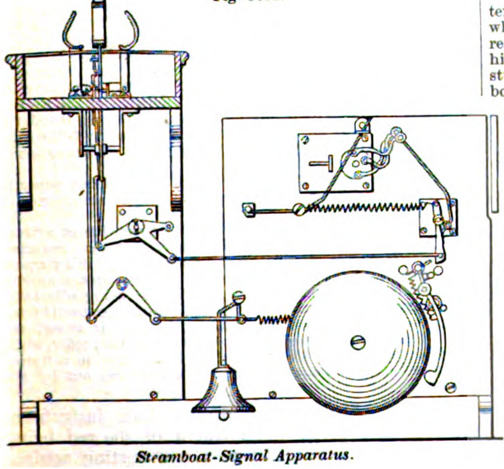
Mr. Wallace's plan was to make a survey with the assistance of a captive balloon, affording a means of distributing notices which might reach the party.

The plan understood to have been adopted was that of Mr. Shepherd. Balloons were inflated and set free, having printed packets of paper or oil-silk, which were distributed occasionally as the balloon traversed across the country. The papers contained directions, stating the latitude and longitude of the exploring ships, the direction in which they were proceeding, and the localities at which provisions had been left. These papers were attached at intervals to a long slow-match made of rope, dipped in niter, and the match, burning gradually away, released the notices consecutively, and thus distributed them over a wide expanse of country.

Mr. Darby constructed signals attached by a string to a hollow fuse, which released the *petard signal*, whose contact with the ground caused an explosion equal to that of a 6-pounder cannon, and released hundreds of little packets of printed notices wrapped in tin-foil. The petard called attention to the spot, and the bright little packages would be easily observed, and would be attractive to the natives by whom they might be discovered.

Mr. Darby had also a bill-distributor attached to his to deliver notices. A third of his devices was a hollow shell containing the information to be disseminated, and a vertical staff with a flag. The tripod base was so arranged as to stand erect on land or water. Our informant states that each of Mr. Darby's plans was tried and worked successfully. See lists under ALARMS; ELECTRICAL APPLIANCES; TELEGRAPH. See also SIREN; SEMAPHORE; RAILWAY-SIGNALS; FIRE-ALARM TELEGRAPH.

Fig. 5081.



Steamboat-Signal Apparatus.

Sig'nal-ap'pa-ra'tus. A device to operate or transmit a signal. It may be mechanical or electrical. Signal-apparatus of various kinds are cited under different heads.

Fig. 5081 is a steamboat-signal apparatus. The movement of a lever by the pilot actuates an indicator traversing the face of a marked dial coincidently with the sounding of a bell. The levers projecting through a plate having slots extending in different directions are caused, by means of wires, to move a lever connected to the shaft of the index by cord attached at different points on its periphery; thus, a greater or less extent of movement on the levers will move the index through a proportionate arc.

Sig'nal-box. A street box having a signaling apparatus connected by wires with a central apparatus for ringing alarms of fire. See FIRE-ALARM TELEGRAPH, page 849.

Sig'nal-lamp. 1. A lamp with white, red, and blue panes or bull's-eyes, for signaling trains. See RAILWAY-SIGNAL.

The signal-lamp of the English railway-service has a bull's-eye in front and a recess between it and the burner, for dropping in any particular colored glass, according to the light which is to be shown. The colored glasses are contained in a pocket, and a red, green, or blue glass can be placed in position by the engineer or signal-man as may be required.

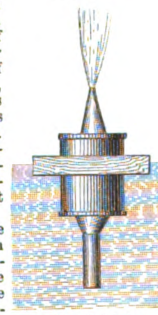
2. Marine signal-lamps or lanterns are displayed at night on board a ship, for the purpose of indicating her position to other vessels and preventing collisions. The United States Naval Regulations provide that a bright white light, sufficiently brilliant to be visible at least five miles, and showing over an arc of ten points on each bow, shall be carried at the foremast-head.

On the starboard side a green light, and on the port side a red light, each to be visible at least two miles, and showing over an arc of ten points, from straight ahead to two points abaft the beam, are to be carried.

Sig'nal-light.

A form of signal-light to be thrown into the water to direct attention of a man overboard, and of rescuing boats, consists of a tin cylinder with conical top, and a float by which it is sustained vertically in the water. The case is charged with phosphide of calcium, secured air-tight therein. For use, the top of the cylinder is cut off and the bottom end of the tube opened, so that water can enter, and evolve gas from the compound, which inflames as soon as it comes in contact with the air.

Fig. 5082.



Signal-Light.

In Fig. 5083, *A B* are side and end elevations of Cooke's apparatus for displaying the electric light from the clock-tower of the Parliament Houses at Westminster.

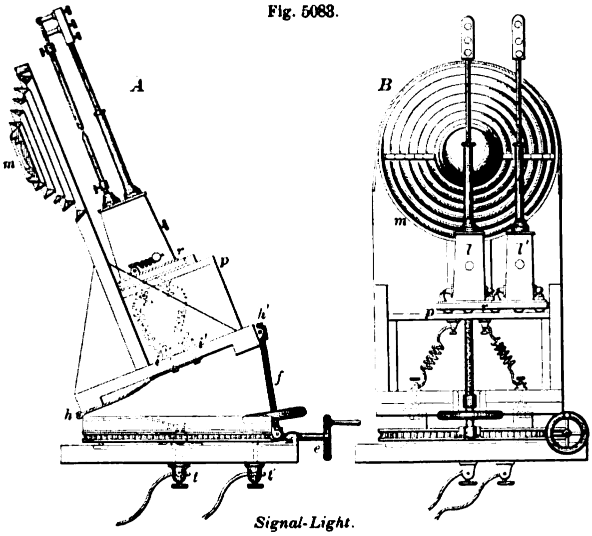
t t' are two screws which receive the terminals of the battery-wires, from whence the positive and negative currents are conducted respectively to the hinges *h h'* of the stand, and thence to the studs *i i'*, which transmit it to the carbon points in the regulators *l l'*; these are fixed upon a board *r*, which slides upon the table *p*, and each carries two copper strips, which make connection with the studs *i i'*, when either lamp is in proper position; when the carbon points of one lamp are near consumed, as *l* for example, it may be pushed over, so that *l'* occupies its place, the interruption of light being only instantaneous; fresh points are then placed in *l*, which in its turn replaces *l'*, the light being thus rendered practically continuous for as long a time as necessary.

By means of the elevating-screw *f* and hand-wheel *e* having a worm gearing with teeth around the periphery of the table *c*, the light, transmitted through a Fresnel lens *m*, may be thrown in any desired direction, either in altitude or azimuth.

Sig'nal-post. A staff for displaying flags or signal-lanterns.

Sig'nal-rock'et. Signal-rockets are composed of a *case*, charged with composition; a *pot* filled with *stars*, *gold-rain*, or *serpents*, and a stick. They are named from the interior diameter of the case, as $\frac{3}{4}$-inch, 1-inch, or $1\frac{1}{2}$-inch rockets.

Fig. 5083.



Signal-Light.

The case is formed of stout paper, which is cut into rectangles in width equal to the length of the case; these are rolled over a wooden former which is of the same diameter as that of the interior of the rocket, the paper is pasted after the first turn, and is drawn around the roller, keeping it perfectly taut as each turn is taken. This is done on a flat table, and successive sheets of paper are added until the required thickness is attained. It is then choked near one end by means of a stout cord wound once around it and drawn taut by means of a treadle, after which the choke is secured by several turns of twine, leaving an aperture large enough for the insertion of the spindle in driving; the case is now dried in the shade.

When dry, the composition may be driven into the case. For this purpose the choke end is cut off square to such a length that when the case is inserted in the mold, the choke shall fit closely over the nipple of the spindle, the end of the case resting on its base; being placed on the spindle, the case is driven firmly down, and the *mold* placed over the case. The mold is a metallic tube, bound with rings; or a block having a circular hole, into which the case fits, may be used for holding the case while driving. For driving, three or more *drifts* are used; these are of the same diameter as the rocket, but of different lengths, and all except the shortest are recessed to receive the spindle.

Fig. 5084.

a, Mold, or Block. b. Spindle. c, Drift. d, Case.

A ladleful of composition is poured into the case and driven down by 25 or 30 blows of a wooden mallet on the head of the drift, which is then withdrawn, and another ladleful of composition poured in, which is similarly treated: the operation is proceeded with in this way, using the longest hollow drift first, and afterward the shorter ones successively until the top of the spindle is reached. The case is then driven one diameter in hight with the solid drift, the composition covered with a paper wad cut to fit the case, over which is driven a wad of clay about ¼ of a diameter in hight.

Cases may be driven without a *mold*, being firmly fastened in an upright position.

The rocket is primed by a piece of quick-match, inserted in the choke-hole and coiled away at the bottom of the composition. A cap of strong paper is then pasted over this end.

The *pot* is a cylinder of rocket-paper, which is slipped over the case at the clay-wad end, projecting about 1½ diameters beyond the end of the case; it contains the ornaments and a bursting charge of powder, and is pasted on to the case.

The *cone* is made by a semicircular piece of thick paper wrapped around a conical wooden former and pasted. This is secured over the end of the pot by a similar cone of thin paper, one inch longer, whose bottom is cut into slips and pasted to the pot.

The stick tapers gradually, being of .6 to .8 of an inch at the large, and .35 to .5 of an inch square at the small end. The large end is that attached to the rocket, and is tied on by means of twine or iron wire. Its length is such that, when attached, the rocket should balance at from about 1 to 2 inches in rear of the case.

These dimensions apply for ¾ to 1½ inch rockets; for larger or smaller ones, they will be nearly in similar proportion to the size.

Marcus Græcus, who wrote about the close of the eighth century, gives the following directions: pulverize in a marble mortar 1 pound sulphur, 2 charcoal, and 6 of salter.; ram some of this powder tightly in a long narrow tube closed at one end, then set on fire, and the tube will fly through the air.

This is a veritable rocket.

Rockets from 3 to 4 inches in diameter ascend from 1,000 to 1,200 yards in from 7 to 10 seconds, and are visible 35 to 40 miles. Rockets of 1 or 2 inches diameter only ascend to from 450 to 600 yards.

Sig'nal-tow'er. An elevated structure, as a beacon, from which to display a semaphore or other signal.

Sig'na-ture. A distinguishing letter or number at the bottom of the first page of each sheet of a book, to indicate its order to the folder and binder.

Signatures are sometimes inserted at the bottoms of other pages, as the third, fifth, and seventh, in octavo, the third in quarto, and so on of the other styles.

The signature of the first sheet of matter is B, A being reserved for the title-page, index, contents, etc.; the next would be C, and so on. The old Roman alphabet, which is destitute of J V W, is adopted, so that the twenty-fourth sheet will be A A or 2 A, according to the custom of the office.

In the United States, numbers are very generally employed to indicate the signature.

About 1469-70, alphabetical tables of the first words of each chapter were introduced, as a guide to the binder. Catch-words (now generally abolished) were first used at Venice by Vindeline de Spire.

The name and residence of the inventor of signatures are doubtful; it appears they were inserted into an edition of "Terence," printed at Milan in 1470, by Anthony Zorat. And an edition of "Baldi Lectura super Codic," etc., was printed at Venice by John de Colonia and Jo. Manthen de Gherretzem, anno 1474: it is in folio, and the signatures are not introduced till the middle of the book, and then continued throughout. Abbé Reve ascribed the discovery to John Koelhof, at Cologne, in 1472. They were used at Paris in 1476, and by Caxton in 1480.

Si-le'si-a. (*Fabric.*) A linen made in Germany.

Si'lex. See SILICA.

Sil'hou-ette. A profile or outline representation of an object filled in with black. The inner parts are sometimes touched up with lines of lighter color, and shadows are indicated by a brightening of gum or other lustrous medium.

The invention has been ascribed to the daughter of Dibutades, a potter of Corinth, who drew the outline of the shadow of her lover's face cast by a lamp upon the wall, about 776 B.C. Her father, the legend relates, cut away the plaster within the outline of the profile, took an impression in clay, and baked it in his oven; this, it is said, was still preserved at Corinth when that city was sacked by Mummius, B. C. 146. Numerous and fine specimens are to be found on ancient Etruscan vases.

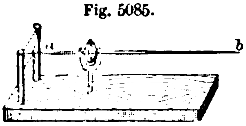
The first notice of the modern practice of the art was in regard to portraits made by Elizabeth Pyberg, who cut the profiles of William and Mary out of black paper, 1699. The name silhouette was given them, about 1757, in derision of the French Minister of Finance, Étienne Silhouette, he having vexed the people of Paris by many salutary and some rather trifling reforms; the wits, therefore, dubbed any very cheap article a silhouette.

It is frequently made by the eye, the artist having paper in one hand and scissors in the other, the subject standing with profile presented.

The portraits may be taken without the exertion of artistic skill, by tracing the shadow of the person and then reducing the portrait to the required size. A machine for this purpose is shown in the adjacent cut. The tracer moves upon a universal joint on the standard, the respective ends being adjustable as to length, so as to suit the required relative proportion between the large view and the miniature copy. In using, one end of the tracer is caused to follow the line of the profile, while the other marks upon the paper which is presented in a frame. The paper is then removed and the portrait cut out by the scissors.

Sil'hou-ette In'stru-ment. An instrument for tracing profiles. The end *a* of the rod being furnished with a lead-pencil and resting against

Fig. 5085.



Silhouette Instrument.

the sheet of paper, a person sits in position that the end *b* of the rod may be made to follow the profile of the features and head, the diminution in the size of the drawing being dependent upon the relative distances of the subject and the paper from the axis of oscillation of the rod. See TRACING-MACHINE; ENGRAVING-MACHINE; PANTOGRAPH.

Sil'i-ca. An oxide of silicon, having the formula Si_2O_4. It occurs nearly pure in quartz rock, chalcedony, flint, and in various other more or less impure forms constitutes an important part of the earth's crust.

Its economic uses are various and important, as in the form of sand, for making mortar, glass, and artificial stone. The sandstones, principally composed of silex, are largely employed in building, and, in combination with alumina and other minerals, it forms granite and many other rocks which are universally diffused over the earth's surface.

Sil'i-con. Equivalent, 21.2; symbol, *Si*. Next to oxygen it is stated to be the most abundant substance in nature. A brown, non-conducting substance; the base of silex or silica, whose formula is Si_2O_4.

Silk. 1. The fine glossy thread spun by the caterpillars of various moths of the genus *Phalæna*. That of the *Phalæna bombyx*, or common silk-worm, is most generally known and used.

The earliest notices of the use of silk are to be found in Chinese annals, as we might expect: these people had the worm, its products, and the means of recording. If we assume with one of the moderates that Hoang-to, who began the culture of silk in China, lived in 1703 B. C., he was contemporary with Joseph, the viceroy of Egypt. The wife of the Emperor, named Si-ling-chi, is particularly credited with the success of the domestication of the worm and the mode of availing its product.

The passage in Ezekiel rendered silk is believed to be a misnomer: probably fine flaxen goods.

Another reference to silk in the Bible is in Revelations xviii. 12, where it is mentioned as among the treasures of the typical Babylon.

For ages after its first importation into the West the Greeks and Romans remained ignorant of the manner in which it was produced. The Greeks, returning from their Persian conquests, 323 B. C., brought back wrought-silk.

One specimen of silk has been found in the Catacombs of Egypt. It is associated with some bead network taken from a mummy at Sakkarah.

The *serica* of the ancients, from whence the silk was derived, and whence its European name, has been identified probably with the modern Khotan.

Procopius calls it Serinda, which terminal denotes the India whence it was derived, or else an indication of the alliance of the two by race, position, or inter-commercial relation.

All the ancient and modern names of silk are derived from the Chinese *Se*, which in Corea becomes *Sir;* in Mandchou, *Sirghé;* was in Chaldee, Arabic, and Syriac, *Seric;* in Greek, *Sericon;* in Latin, *sericum;* in Anglo-Saxon, *seolc*, and so on.

The first ancient Western author who mentions it distinctly is Aristotle; in his time it is believed to have been imported in skeins from Asia and woven in Cos. The references to it in later authors are numerous. Crassus found that the Parthian troops had silken flags attached to gilt standards. The silken and embroidered robes of Cleopatra are celebrated by various authors, — Lucan, for instance. It long remained an expensive luxury: Heliogabalus, it is said, being the first Roman who had a complete silken garment; and silk was worth its weight in gold in the time of Aurelian. At the end of the third century it was worked with a warp of linen or wool, and became more common.

The history of the introduction of silk culture into Europe is thus related by Procopius ("De Bello Gothico," IV. 17): —

"About this time [A. D. 530] two monks having arrived from India, and learned that Justinian was desirous that his subjects should no longer purchase raw-silk from the Persians, went to him and offered to contrive means by which the Romans would no longer be under the necessity of importing this article from their enemies the Persians or any other nation. They said that they had long resided in the country called Serinda, one of those inhabited by the various Indian nations, and had accurately informed themselves how raw-silk might be produced in the country of the Romans. In reply to the repeated and minute inquiries of the emperor, they stated that the raw-silk is made by worms, which nature instructs and continually prompts to this labor; but that to bring the worms alive to Byzantium was impossible; that the breeding of them is quite easy; that each parent animal produces numerous eggs, which are hatched by the heat of manure. The emperor having promised the monks a handsome reward if they would put in execution what they had proposed, they returned to India and brought the eggs to Byzantium, where, having hatched them in the manner described, they fed them with the leaves of the black mulberry, and thus enabled the Romans thenceforth to obtain silk in their own country."

Western Europe was long supplied from this point. The manufacture was introduced into Spain by the Saracens.

In 780, the Emperor Charlemagne sent Offa, king of Mercia, a present of two silken vests, indicating the esteem in which the material was then held.

In 1147, Roger II. of Sicily, returning from Palestine, plundered Athens and Corinth, seized workmen who understood the silk manufacture, and introduced it into his own dominions. From thence it slowly spread to Italy and France. Louis XI., in 1480, obtained Italian workmen and established the manufacture at Tours, and in 1521 Francis I. established a colony of Milanese at Lyons.

The manufacture was encouraged in England by James I. in emulation of his "Brother the French King," as he styles him. The revocation of the Edict of Nantes by Louis XIV., in 1685, drove 50,000 Protestants from France, and materially aided in spreading the manufacture of silk, crystal glass, jewelry, and other fine goods, in which that nation of *émeutes* and artists so highly excelled.

In 1717, John Lombe obtained by stealth from Sardinia a model of the silk throwing-mill, and set up silk-works in Derby, England. The works afterward devolved upon his brother William, and then reverted to a cousin, who became Sir Thomas Lombe, whose name is also creditably associated with the pursuit of the enterprise.

Silk from spiders was spun, in 1710, by Bonn, a Frenchman, who manufactured with this material both stockings and gloves. He estimated 12 house-spiders = 1 silk-worm.

The Arachnidæ have engaged other artists not belonging to the great college of Laputa, and a patent of the United States was granted to some officers of the United States Army, January 9, 1866. They appear to have found in South Carolina some spiders of wondrous fibrous fecundity, and patented a machine in which the Arachnidæ are secured upon a frame, their spinnerets being so presented as to yield their webs to be associated and wound upon a spool. The legs are drawn back out of the way of interference while the reeling proceeds.

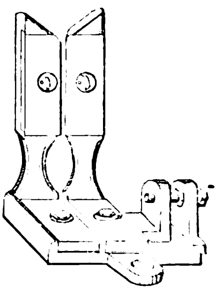
2. (*Fabric.*) A fabric woven from silk. There are many varieties, different in the fineness, density, and finish, such as —

Shot-silk.	Tissue.
Lutestring.	Gros.
Satin.	Moire-antique.
Satinet.	Ribbon, etc.

For specific list of appliances in the treatment and manufacture of silk and other fiber, see COTTON, FLAX, WOOL, HEMP, SILK, etc., APPLIANCES.

Silk-clean'ing Knife. An implement for freeing the fiber from gummy impurities and other dirt. It is drawn over or between knife-edged surfaces, which exercise a scraping action.

Fig. 5086.



Silk-Cleaning Knife.

Silk-cot'ton. A short silky and elastic fiber obtained from the *bombax* and some other trees. It is employed by the Hindoos for producing a coarse and loose yet warm kind of cloth, and has been used instead of silk for covering hat-bodies.

Silk-cul'ture. The series of operations in silk-culture is as follows: —

1. The insect, the *Bombyx mori*, deposits eggs smaller than a grain of mustard-seed.

2. Each egg hatches into a caterpillar less than one quarter of an inch long, acquiring a new skin as often as the old one becomes too small; four of these *molts* or renewals take place, at the end of which the worm is three inches long.

3. The full-grown worm, ceasing to eat, begins to expel the silk from two orifices in the head.

4. The silk, at first a glutinous gum, hardens into a thread or fiber, which the insect winds into a hollow ball around itself. This is the cocoon.

5. The body of the worm gradually lessens in bulk, while the cocoon becomes gradually larger as the silk is withdrawn from the body of the worm.

6. The cocoon being finished, the worm changes into a chrysalis.

7. In two or three weeks the chrysalis becomes a moth and eats out of its prison.

8. The moths of the respective sexes provide for a new generation of eggs, which are deposited, and then the parents die.

The silk-worm will flourish, with care, in moderately temperate climates, though tropical and subtropical regions are its peculiar habitat. The extreme east of Asia, — China and Japan, — which have a climate differing but little from that of the Southern United States, appear to be more favorable to the development of the insect than any other part of the world; at least, it seems to require less care there, though they are grown in great perfection in Italy and Southern France. There seems no reason, apart from the higher cost of labor, why our own country should not be able to produce all the raw-silk required for its own consumption. Previous to the Revolutionary War, large quantities were raised in Georgia; and during the *Morus multicaulis* mania of some thirty-five years ago, silk of unsurpassed quality, and fabrics therefrom which compared favorably with the products of foreign looms, were produced.

The worm, however, not being able to endure great atmospheric changes, requires, in our climate, careful attention. Its eggs, also, to prevent premature hatching, must be carefully kept in a cool place during the summer season.

When first hatched, which is done by exposing the eggs to a sufficient warmth, the young worms, then scarce one quarter of an inch long, are placed in contact with the food, mulberry-leaves generally, which is to form their future subsistence. The white mulberry (*Morus alba*) is largely used in Southern Europe, and it is claimed by some to produce a stronger, though coarser silk than that derived from worms fed on the *Morus multicaulis* (many-stemmed) or paper-mulberry, which is the favorite in China, and which was at one time very extensively planted in this country. The worm, however, can subsist on other leaves.

A writer in a French scientific periodical states that by feeding silk-worms on vine-leaves he has obtained cocoons of a magnificent red, and, by feeding them on lettuce, others of a very deep emerald green. Another silk-grower has obtained cocoons of a beautiful yellow, others of a fine green, and others again of violet, by feeding the silk-worms on lettuce or on white nettle. He says that the silk-worms must be fed on mulberry-leaves when young, and supplied with the vine, lettuce, or nettle leaves during the last twenty days of the larva stage of their life.

However this may be, the fact in practical silk-worm raising is that the worm, when placed on the leaves, eats continuously, with the exception of intervals when it lies by to molt, until it attains its full size, about three inches in length; it then selects a place about the frame where it is reared, in which to spin its cocoon. When the cocoon is spun it is necessary to kill the contained insect before it develops into a moth, reserving a certain proportion to lay the eggs which are to form a future supply.

This is done by baking at a low heat.

The filaments are then reeled off as described under SILK-REEL, and the various processes necessary for the completion of the fabric, whatever it may be, are proceeded with in the manner treated of under SILK-MANUFACTURE. See Figuier's "Insect World," pp. 214 - 250.

The cocoons are divided into nine qualities by the French.

1. *Good cocoons;* free from blemishes and well shaped.
2. *Calcined cocoons;* having worms which died after completing their work.
3. *Cocalons;* somewhat loose in texture.
4. *Choquettes;* having worms which died before finishing their work.
5. *Dupions;* double cocoons, difficult to detach.
6. *Soufflons;* loose cocoons, difficult to unwind.
7. *Pointed cocoons;* with a damaged point at which the thread breaks.
8. *Perforated cocoons;* at which the moth has escaped.
9. *Bad choquettes;* the silk spotted, rotten, blackish.

Silk-doub'ling Ma-chine'. A machine for twisting together two or more filaments of twisted silk. See DOUBLING, 5, page 731.

Silk-loom. (*Weaving.*) A loom specifically constructed for weaving silk. See WEAVING; LOOM.

Silk-man'u-fac-ture. The processes intervening between the making of the cocoon and the preparation of the silk for market.

1. The chrysalis is killed within the cocoon by the application of heat before it has developed into a moth.
2. The *floss silk* is stripped from the exterior of the cocoon.
3. The cocoons are placed in warm water, to loosen the gummy adherence of the filaments.
4. The filament ends are carried around a reel and wound into a skein.
5. The skeins are made up into hanks or bundles, forming the *raw silk* of commerce.

The length of each filament is usually about 300 yards; 250 average cocoons weigh about 1 pound; 12 pounds of cocoons yield 1 pound of silk = 3,000 cocoons to 1 pound of silk. — DODD.

6. The raw silk is wound from the hanks in which it is brought to market on to hexagonal frames, called swifts, and is thence transferred to bobbins.
7. *Clearing.* To remove irregularities from the surface, each thread is caused to pass under a steel scraper or between two rollers. This is done by the *clearing*-machine, where it is wound upon other bobbins.
8. *Spinning.* The spinning-machine is provided with a number of rapidly rotating spindles by which a twist is imparted to the filaments drawn from the bobbins taken from the clearing-machine, as they are transferred to another set of bobbins.
9. *Doubling.* Two or more of the filaments are twisted together, and at the same time wound upon bobbins by the *doubling*-machine.
10. *Throwing.* The *throwing*-machine twists and combines the threads in a manner nearly similar to that of the spinning-machine. For some purposes the two operations are combined; for others the throstle-frame is employed.
11. *Glossing.* After throwing, the silk is usually dyed, and is then transferred to the *glossing*-machine, where, by the combined action of steam and stretching, it is elongated and a glossy surface is imparted. The fibers may be stretched in length one tenth.
12. *Winding.* The various processes enumerated having been completed, the silk is again wound upon bobbins, and is ready to be woven.

The quality of silk is denoted by the number of yards to the *denier*, a weight equal to 24 grains.

Silken thread merely wound and cleaned is called *dumb singles;* when wound, cleaned, and thrown, *thrown singles;* if single-twisted, *tram;* if double-twisted, *organzine;* if the natural gum is left, *hard silk;* if removed, *soft silk*.

For silk gauze, *dumb singles* is employed.
For ribbons and common silks, *thrown singles*.
For the weft threads of the best silk, *tram*.
For the warp threads of the best goods, *organzine*.

Floss silk is the outer portion of the cocoon; it is worked up into yarn for cheap handkerchiefs, shawls, and other coarse fabrics, by processes somewhat resembling cotton spinning.

After sorting, the filaments are disentangled by a hackling process, being held firmly at one end while the other is drawn over a set of *gills*.

At the *filling-engine*, the silk, while passing between feeding-rollers, is subjected to the action of a series of moving combs.

The *drawing-frame* holds the filaments firmly by one end while a comb travels over their surface to remove impurities and short fibers.

The *cutting-engine* acts like a tobacco or chaff-cutting machine, and cuts the parallel filaments into lengths of about $1\frac{1}{4}$ inches.

The *scutcher* converts these short fibers into a sort of down, which is washed in soap and water, boiled in pure soft water, pressed, dried, scutched to loosen it up, carded, made into slivers, drawn, doubled, drawn, rove, and spun, like cotton.

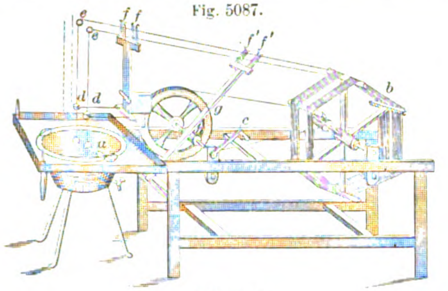
Silk-mill. A building where silk is reeled, spun, and woven.

Silk-reel. An apparatus for unwinding silk from the cocoon. The glutinous quality of the filament when first spun by the worm causes the threads forming the cocoon to adhere closely together, requiring the action of heat and moisture to effect their separation.

For this purpose the cocoons are placed in a shallow pan of water *a* heated by a furnace beneath. The ends of several filaments are united and attached to the reel *b*, to which motion is imparted by turning the crank *c*. The threads pass upward through glass eyes *d d* over rollers *e e*, by which a slight twist is imparted, and are guided by cylinders of porcelain *f f f' f'* to the reel. The shaft *g*, on which the latter pair of guides is placed, is caused to traverse from side to side by a pin on its under side working in a cam-groove in the roller *h*, so as to distribute the thread on the reel. Unless this be done it cannot be unwound, and is consequently unsalable.

One of the arms of the reel is provided with a screw, so that it may be shortened when desired to remove the skein. It is screwed out again for winding.

Fig. 5087.



Silk-Reel.

The automatic silk-reel is designed for unwinding the thread from the blocks of the throwing-mill and winding it into hanks.

Silk-shag. (*Fabric.*) A coarse, rough, woven silk with a shaggy nap.

Silk-siz'ing Ma-chine'. See SILK-SORTING MACHINE.

Silk-sort'ing Ma-chine'. A machine by which silken threads of various thicknesses are sorted into sizes between certain limits and wound upon separate bobbins, according to size.

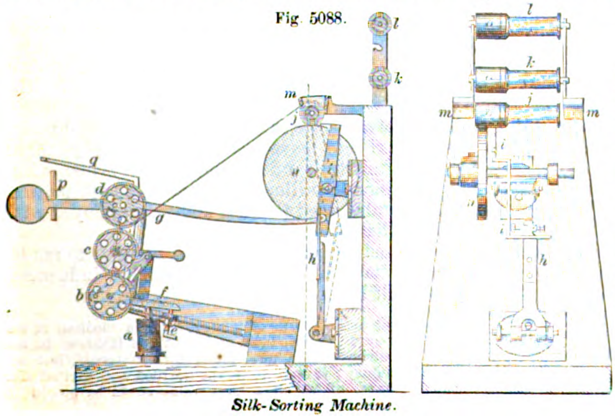
Fig. 5088 is Atwood and Leigh's machine. The thread from the bobbin *a* passes to and between the gage-rollers *b c d*, which have a certain bearing on each other, and are simultaneously raised or lowered by turning the adjusting-screw *e*, operating the pivoted lever *f*, on which the journals of the lower roller rest. The shaft of the upper roller is connected with a lever *g*, the shorter arm of which is weighted so as to nearly counterbalance the preponderance of the other arm, which is forked at the end, straddling the upper end of the lever *h*, which bears against the lower bent arm of the lever *i*, so that the two constitute a compound lever.

The silk is wound from the roller *d* on to one of the bobbins *j k l*, each of which receives a different sized thread between certain limits. Either of these bobbins, depending on the size of thread being delivered, is placed in bearings in the arms *m m*, where it is turned by the revolution of the drum *n* bearing against the cylindrical portion *o* of the bobbin. The upper end of the lever *h* has two notches on one side and one on the other, and the fork of the lever *g* has two inwardly projecting pins, one on each side. The lever *h* may be shifted from side to side, so that one of these pins may bear against either its front or back, for the purpose of adjusting the delivery of the thread. If this should vary from the prescribed limits, the lever *g* tilts, throwing backward the lever *h*, which, in turn, operates the lever *i*, causing its upper cam-shaped extremity to come in contact with the roller *o* on the end of the bobbin, and lift it out of contact with the drum *n*, so that it ceases to revolve. One of the bobbins *k l* is then substituted, the thread is broken, and its end is attached to the bobbin, and wound thereon so long as the bobbin continues to act, or until it is thrown out of contact with the drum *n*.

In case the thread becomes so thin as to endanger its breakage, the lever *g* drops until the adjustable set-screw *p* comes in contact with the stop *q*, throwing the middle and lower rollers out of frictional contact, and they cease to deliver.

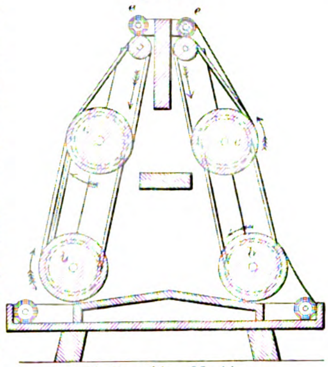
By having a larger number of rollers and slightly modifying the stop arrangements, the machine may be adapted to sort more than three sizes of thread.

Fig. 5088.



Silk-Sorting Machine.

Fig. 5089.

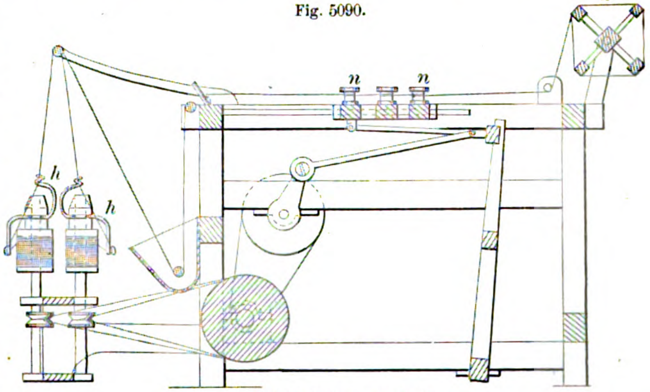


Silk-Stretching Machine.

Silk-stretch'ing Ma-chine'. An apparatus for imparting the proper tension to silk fibers.

In the example, the ends of the fibers, reeled on bobbins placed at the lower part of the frame, are moistened and attached to drums *B B*, whose motion unwinds them from the bobbins; when all is wound off on to the drums *B B*, the free ends of the fibers are similarly attached to the drums *C C*, which are set in motion, unwinding and stretching the fibers from the drums *B B* on to themselves. The final stretching is effected by the bobbins *E E*, which draw the silk from the drums *C C* and over a series of rollers, one for each thread. Winding from the lower bobbins on to the lower drums, and from the upper drums on to the upper bobbins, may be effected simultaneously.

Fig. 5090.



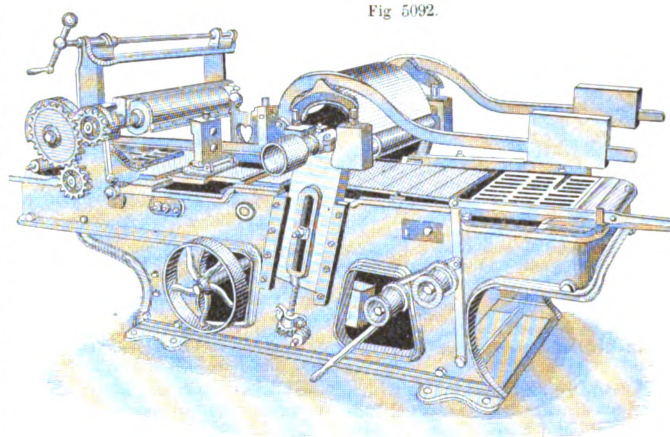
Silk Twisting and Reeling.

Silk-throw'ing Mill. At the commencement of the eighteenth century, silk machinery was so imperfect in England that the supply of thrown silk was chiefly derived from Italy. In 1717, John Lombe returned from Italy with drawings of the machinery employed in that country, where the process was kept as a profound secret. He obtained access to the mills by bribing the workmen, and committed the results of his observations to paper at night. Having been discovered, he with great difficulty made his escape. In 1718 he obtained patents for the improvements thus introduced, and in 1719 erected a mill on the Derwent at Derby, 5 stories high and $\frac{1}{8}$ of a mile

in length, which was considered one of the wonders of the age.

Silk Twist'ing and Reel'ing. In the apparatus (Fig. 5090), the silk previously wound upon spools is twisted by the flyers *h h*, then macerated in a trough, coiled upon the rollers *n n*, and finally wound upon the reel *u*.

Fig 5092.



Fay's Sill-Dressing Machine.

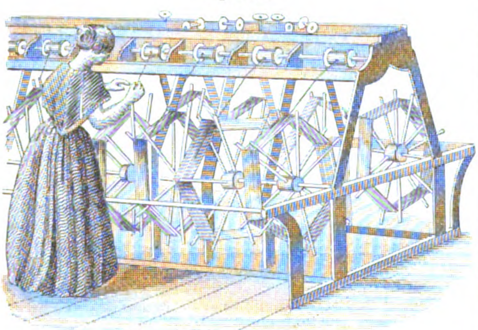
Silk-wind'-er. (*Silk-manufacture.*) *a.* The reel on which silk is wound from the cocoons. See SILK-REEL.

b. The machine on which raw silk in the *hank* is transferred to bobbins preparatory to spinning.

Each hank is extended upon a light six-sided reel, called a *swift*, a number of which are arranged on axes on each side of a frame. The bobbins, one for each swift, are arranged above them.

The ends of the filaments on the swifts are connected to the bobbins, and the swifts are set in motion, causing the bobbins to turn and deliver the silk.

Fig. 5091.



Silk-Winder.

The swifts are adjustable to receive hanks of varying sizes, and have a friction device on the axis, to prevent them from turning faster than the bobbins can take the silk. The filaments pass through eyes on a rod having an endwise traversing motion, which lay them spirally and evenly upon the bobbins.

Fanshaw's silk-winder, English patent, 1827, was designed to avoid the breakage of the filament in winding the skein silk on to bobbins. Instead of mounting the skein on a reel, which is rotated by drawing upon the thread, the reel is made stationary, and a revolving flyer passes around and lifts the thread, which passes over a roller, thence to the center of rotation, and is then wound upon a bobbin.

Silk-worm Gut. A fine cord for angling, made of the silk-gut of the worm.

Fine worms about to begin spinning, being selected, are killed by immersing in vinegar. After steeping for about twelve hours, a worm is removed and pulled apart, exposing two transparent yellowish-green cords. These are stretched to the required extent, and fastened in the elongated condition on a board to dry.

Sill. 1. (*Carpentry.*) The lower timber in a wooden structure, — in a building, a loom, a bridge, a door or window frame, etc., etc. Nearly synonymous with *sole*; but the latter refers more specially to moving objects, such as a plow, a shoe, a sled, etc.

Sometimes called *ground-sill.*

2. (*Fortification.*) The inner edge of the bottom or sole of an embrasure.

3. (*Mining.*) The floor of a gallery or passage in a mine.

Sill-dress'ing Ma-chine'. A special kind of wood-planing machine for dressing heavy timbers on two or more sides, for car-bodies or other structures. It has various adjustments for different thicknesses and widths of stuff.

Sil'lon. (*Fortification.*) A work raised in a ditch to defend it if too wide. It must be lower than the main works, but higher than the covered way.

Si'lo. A large shallow ditch protected by thatch or boards from rain, sun, and air, and used as a store-pit for potatoes or beets designed for starch-making or the manufacture of beet-root sugar.

Si-lom'e-ter. (*Nautical.*) An instrument for measuring, without the aid of the log-line, the distance passed over by a ship. Various forms have been proposed or actually constructed. See LOG; VELOCIMETER; and list under METER.

Sil'ver. Equivalent, 108; symbol, *Ag.* (*argentum*); specific gravity, 10.5; point of fusion, 1873° Fah. Generally occurs as a sulphide, and is often associated with other metals. The ore is ground and the silver separated by amalgamation. See AMALGAMATOR.

It is a clear white, malleable, ductile metal; may be extended into leaves not exceeding $\frac{1}{10000}$ of an inch in thickness and drawn into very fine wire; has considerable brilliancy and takes a high polish.

The metal is used for coin and plate, alloyed with copper to harden it.

It is used to coat metals (see PLATING) to render them less liable to change by atmospheric influences, but is itself liable to be attacked by sulphur.

Silver is the earliest form of money, being a medium of exchange in Assyria, Egypt, Tyre, and with the Hebrews in the time of Abraham. Gold was valued for ornaments, but not current as money; it was no doubt hoarded and carried like precious stones, of which a large value could be placed in a small compass.

Silver was also used for ornaments; "jewels of silver" and

"jewels of gold" were given by Abraham's servant to Rebecca; "a golden ear-ring of half a shekel weight, and bracelets for her hands of ten shekels weight of gold."

Vessels of various kinds and images were also made of it, and at a very early day.

It is generally allowed to be the best material for drinking-vessels and table-ware, and has been a favorite therefor in all historic ages. Joseph, who was viceroy of Egypt, speaks of "*my* cup, the *silver* cup."

The images (*terraphim*) which Rachel stole from her father Laban were no doubt of silver.

The ancient notices of silver are numerous, both as a medium of exchange and for articles of use, ornament, and luxury.

A traveler in Honduras describes the primitive mode in which silver ores are treated by the Indians in that country. "The man disappeared in a hole in the hillside, and presently appeared with a lump of ore. The man and woman then selected each a flat stone, and began pounding the ore, which was thus gradually reduced to the condition of a gravelly dust. The fire, meanwhile, was fed largely by the children; a small earthen pot, holding a portion of the *brosa*, was set deep in a bed of coals. The wood was piled over it, sulphurous vapors escaped, and when the whole had burned fiercely awhile and fallen to ashes, our son of Tubal Cain drew forth the pot and turned out upon the ground a mass of gray, black, and red slag and ash, out of which I drew with a stick a button of red-hot silver, weighing, perhaps, two ounces."

Fig. 5093.

Indian Silver-Miner.

An antique appearance may be given to silver by exposing it to the fumes of hydro-sulphuret of ammonia, or immersing it for a short time in the solution.

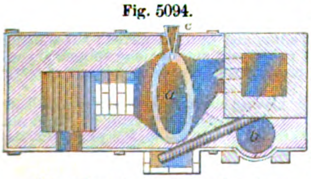
The salts of silver are much used in the arts, — the protoxide and nitrate in photography, the nitrate in hair-dyes and indelible ink.

Silver is separated from lead by repeated melting and crystallization of the lead; the crystals of lead being removed at each operation, the remainder becomes richer in silver, which is then removed by a process similar to that described under ASSAY.

The fact that the richer portion is less fusible than that containing a greater proportion of lead, is utilized in the Pattinson concentration process. See PATTINSON'S POTS, page 1638.

The silver-from-lead-extracting furnace, which may be considered as performing the process of cupellation on a large scale, employs the agency of heat and air-blast in the oxidation and removal of the lead, the alloy being exposed in a shallow pan of bone-dust aggregated in a basin-shape within an oval frame of iron, and forming the hearth of the reverberatory. This hearth is called a *test*, and is supported by a fixed iron ring, called the compass-bar, in the furnace.

Fig. 5094.



Silver-from-Lead-Extracting Furnace (Plan).

The alloy of lead and silver flows into the *test* *a* by a spout from the melting-pot *b*, and the lead on the surface becomes oxidized. The air-blast, entering at the tuyere *c*, blows the supernatant oxide toward the opposite end of the oval hearth, when it flows over the depressed portion of the wall of the cupel, and is collected in a pot below.

As the lead is thus removed, fresh alloy flows from the pot *b*, and the process is continued until a profitable concentration of the silver is attained. The charge is then withdrawn, and the process repeated on a new lot of alloy. The concentrated results of a number of charges are treated in a similar furnace, the dross of oxide being removed by skimming. The eventual refinement is known by the *lightening*, a peculiar brightness incident to the face of the molten metal when the last film of litharge is dissipated and before the cooling of the silver itself begins to take place.

Some beautiful similes have been drawn by the Hebrew writers from the silver-refining process, the *brightening*, which manifests the perfection of the process, being held to be a type of the condition of the human soul purified by trials and perfectly reflecting the face of Him who sits "as a refiner and purifier of silver."

In 1850, Mr. Alexander Parkes patented in England a process for extracting silver from lead by means of zinc. This is now employed in various works in Prussia and France; and it is claimed that ores containing but 8 ounces of silver to the ton can be profitably worked by it.

The process is conducted in large cast-iron Pattinson pots, holding from 10 to 12 tons of lead. The lead is melted and the zinc introduced in three portions, the first being $\frac{2}{3}$, the second $\frac{1}{4}$, and the third $^{1}/_{12}$ of the whole amount used. When the first portion is melted, it is mixed in by rabbles and perforated ladles, or by a mechanical stirrer, for 20 or 30 minutes, when the fire is withdrawn, the metal covered with wet coal-slack, and allowed to cool slowly; the zinc, having formed an alloy with the silver in the lead, rises to the surface. The spongy crust or silver sponge, which forms on top, is taken off to the depth of about two inches, when the lead begins to crystallize; it is again heated up, the second portion added, and treated in the same manner as before. After the second sponge is removed, some liquefied lead, which is subsequently removed from the sponge, and contains a little silver, is added, together with the last portion of the zinc, and the same operation again proceeded with. The whole process takes some 20 or 24 hours. The silver sponge takes up the copper and gold from the lead, leaving behind the antimony and bismuth.

In Balbach's method of using zinc for separating the precious metals from lead, a sufficient quantity of zinc to take up all the silver and gold, say 20 to 80 pounds to the ton of lead, is fused in a kettle, and the molten lead, slightly purified by the process of fusion, is allowed to flow into the kettle, while the zinc is thoroughly incorporated by stirring. The alloy is then cast into pigs, which are placed in a furnace having an inclined hearth, and heated sufficiently to melt the lead, but not the zinc, silver, and gold. The pure lead is drawn off, leaving an alloy of the latter metals in the furnace, to be afterward separated by farther reduction.

The silver processes of Freiberg, Saxony, are about as follows:

The *barrel-amalgamation* process, see page 77.

The *hot-water process*, in which the ores of silver are roasted, so as to give soluble sulphates of silver, which are dissolved out by hot water, and metallic silver is thrown down by copper.

The common *salt process*, in which the ores are roasted to a chloride, and the latter dissolved out by a strong solution of common salt, and the metallic silver thrown down by copper.

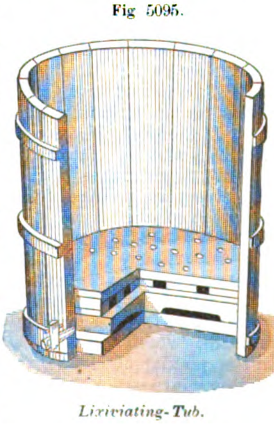
The extraction of silver from lead ores by fusing them with sulphurets of iron, forming a regulus or *matt*, which has the power of dissolving metallic silver and extracting it from the lead.

The solution and precipitation processes are more modern than the mechanical modes, and appear to be principally in vogue on the Continent of Europe. Great completeness and promptness are claimed for them. They are recommended especially for silver in which copper rather than lead predominates.

Augustin's process consists in roasting with salt, for the conversion of the silver into a chloride; lixiviation with hot brine to dissolve the chloride; and precipitation of the silver in a metallic state by exposure of the solution to copper.

The material operated on at Freiberg, in Saxony, is a matt containing about 70 per cent of copper and 0.0042 of silver. It is ground and bolted, and is then roasted for 8 hours to expel sulphur, being stirred during the operation to prevent caking. Being again ground, it is roasted for three hours with the addition of 5 per cent of salt. By the agency of the sulphuric acid of the metallic sulphates, the chloride of sodium is decomposed and the chlorine combines with the silver to form chloride of silver.

Fig 5095.



Lixiviating-Tub.

The material, after cooling, is placed in lixiviating-vats with

perforated false bottoms and filtering-cloths, and a stream of hot brine passed through it. The chloride of silver is thus dissolved and carried off in the hot chloride of sodium, and is conducted to tanks in which foreign matters are allowed to settle. The supernatant liquor is then drawn off into filters in which it passes through layers of *cement copper*, which precipitates the silver, the chlorine uniting with the copper and passing off therewith as a solution of chlorides of sodium and copper, leaving the silver behind. The solution is then filtered through scrap-iron, which causes a deposit of the copper, which is to be used again in the vats above. The brine is reboiled and re-used. The silver is removed occasionally from the lixiviating-vats.

Ziervogel's process supplanted the Augustin process in 1857. It consists in converting the silver into a sulphate and dissolving it out with hot water.

The operation is, briefly, as follows: A finely ground matt containing sulphides of copper, iron, and silver is roasted in a reverberatory furnace. The iron and copper first pass into sulphates, and then become oxides. The silver commences the same series, but subsequently to the other metals. The operation is arrested at the point when the iron and copper have become oxides, and the silver exists as a soluble sulphate removable by water; after which it is precipitated in a metallic state by being filtered through cement copper, and by the addition of chloride of sodium.

Von Patera's process consists (1) in roasting the ores with the addition of salt to convert the silver into a chloride; (2) dissolving out the chloride by means of a cold dilute solution of hyposulphite of soda; (3) precipitating the silver in the form of sulphide by the addition of polysulphide of sodium; (4) reducing the precipitated sulphide of silver to the metallic state, by exposing it in a muffle at a high temperature to the ordinary influences of atmospheric air.

The ore is roasted with addition of steam at the latter part of the process. It is then withdrawn, cooled, ground, and receives an addition of 6 to 12 per cent of salt and 1 to 3 per cent of sulphate of iron. This is introduced into a furnace where it is heated and stirred and receives jets of steam upon its surface. The heat is gradually increased, and may last 10 to 16 hours. The purpose of the addition of the sulphate of iron is to assist in the decomposition of the chloride of sodium if the metallic sulphate should prove to be present in only small quantity. The steam makes the chlorination of the silver more energetic, and assists in the condensation of the former in the chambers interposed between the furnace and chimney. The silver now exists as a chloride, insoluble in water, and the sulphates and chlorides of copper, zinc, nickel, cobalt, iron, etc., are removed by lixiviation.

The remaining pulverized ore is then lixiviated with a cold aqueous solution of hyposulphite of soda, which carries off the chloride of silver, which is precipitated from its menstruum by polysulphide of sodium. The clear liquor is decanted and used for fresh lixiviations of roasted ore; the residual sulphite of silver is drained, pressed, dried, washed, dried, and then heated to redness in a muffle, through which a current of air is passed to remove the sulphur. It is now melted in crucibles, traces of sulphur being removed by the addition of iron, which forms a ferruginous sulphide, and is skimmed off. A sprinkling of wood-ashes and bone-ash absorbs remaining impurities, and is scraped off, leaving the silver practically pure.

On pp. 71-88 of the first volume, AMALGAMATOR, are numerous examples of machinery for working silver ores and auriferous sand or quartz. The arrastra may or may not be an amalgamator, depending upon the presence or absence of mercury. In the latter case, it is a mechanical muller, and is used to perfect the work of the stamps by a more perfect trituration of the ore (see ARRASTRA). Other machines for the treatment of the ores of precious metal are described under ORE-STAMPS; ORE-GRINDING MILLS; ORE-CRUSHERS; CALCINING-FURNACE; REFINING-FURNACE; GOLD-WASHER; CHLORINATION OF GOLD; GOLD BY LEAD-BATH. See list under METALLURGY.

Sil'ver Al-loy'. See ALLOY, page 63; MOCK-SILVER, page 1457.

In 1873, a patent was granted to Mme. Baudoin of Paris for an imitation silver-alloy, composed of copper, 71; nickel, 16.5; cobalt, 1.75; tin, 2.5; iron, 1.25; zinc, 7. In some cases, a small proportion — say, ½ per cent — of aluminium is added.

The silvery appearance of this alloy is due principally to the cobalt.

Sil'ver, Im-i-ta'tion. See MOCK-SILVER, page 1457; ALLOY, page 63.

Sil'ver-ing. Covering the surface of baser metal or other material with silver. When the silver is in the form of leaf, the operation is analogous to that of GILDING (which see).

In the plating of metals, the principal steps are the following: —

The *smoothing down* and polishing the surface of the plate to be silvered.

Annealing. Heating the plate red hot and plunging it into dilute nitric acid until perfectly clean.

Pumicing. Cleaning the surface with pumice-stone and water.

Warming. Heating until the plate slightly hisses, when it touches water, after which it is dipped in dilute nitric acid, causing a slight roughness of the surface, which retains the silvering.

Hatching. When the surface is not thus rendered sufficiently rough, it is gone over with a graving tool; chased surfaces, however, need not be touched.

Bluing. Heating the piece until its surface assumes a bluish tint.

Charging. The workmen's term for silvering. The leaves of silver are placed on the piece while heated, and fixed to its surface by a burnisher. The workman operates on two pieces at once, so that while he is applying the leaf to one the other is being heated.

After applying two silver leaves, the piece is heated to the same degree as at first, and four more leaves are then laid on with the burnisher. He thus applies the leaves successively one over another until the required thickness is attained, and afterward burnishes the surface with a strong pressure.

In silvering with precipitated chloride of silver, a solution of common salt is added to a solution of nitrate of silver, and the resulting white mass is washed and dried; 1 part of this powder is mixed with 3 of good pearlash, 1 of washed whiting, and 1½ sea salt. After cleaning the surface of the brass, it is rubbed with soft leather or cork, moistened with water and dipped into the above powder. After silvering, the surface is washed with water, dried, and varnished. Some use a mixture of 1 part of the silver precipitate with 10 of cream of tartar.

Inferior plated buttons are silvered with a mixture of 1 ounce corrosive sublimate, 3 pounds common salt, and 3 pounds sulphate of zinc made into a paste with water; this is smeared over the buttons, which are then heated to expel the mercury, and afterward burnished.

Leather is silvered by applying a coating of parchment-size or spirit-varnish, and afterward coating with silver-leaf under pressure.

The silvering of glasses and mirrors by the electro-plating process is accomplished in the bath of silver solution in the usual way, the glass being perfectly clean. See next article. See also PLATINIZING, page 1741; LOOKING-GLASS, pages 1350, 1351; MIRROR, pages 1452, 1453; GLASS-SILVERING, pages 982, 983.

Sil'ver-ing Glass.

In Liebig's process (Wagner's "Jahresbericht," Vol. II. pp. 168-171), to an aqueous solution containing 10 grammes nitrate of silver in 200 cubic centimeters, is added sufficient ammonia to clear it, and afterward 450 cubic centimeters of a solution of soda (free from chlorides), specific gravity 1.035; the precipitate produced is dissolved by adding liquid ammonia, saturated with oxide of silver, until the volume is increased to 1,450 cubic centimeters, when dilute solution of nitrate of silver is added: a gray precipitate is formed, water sufficient to bring up the bulk of the liquid to 1,500 cubic centimeters is lastly added. Shortly before applying the silvering liquid it is mixed with $\frac{1}{6}$ to $\frac{1}{8}$ its volume of a solution of milk sugar. After the silver has become attached to the glass, it may be polished with fine rouge and a cloth, and varnished with an alcoholic solution of gum-dammar. Liebig finally, however, recommended the following: Dissolve 1 part nitrate of silver in 10 parts distilled water. Form solution of nitrate of ammonia, specific gravity 1.115; a sulphate of ammonia solution, specific gravity 1.105, may also be used. Prepare a lye of carbonate of soda, having a gravity of 1.035, and reduce three volumes to two by evaporation. The silvering liquid is composed of ammoniacal solution, 100 volumes; silver solution, 140 volumes; lye solution, 750 volumes. The reduction liquid is composed of: *a*, 50 grammes rock-candy, dissolved in water; 3 grammes tartaric acid are added, the liquid boiled for 1 hour, and diluted with water, forming a bulk of 500 cubic centimeters; *b*, 2.857 grammes tartrate of copper are covered with water, and soda lye is added until dissolved; the solution is diluted to form 500 cubic centimeters: one volume of each of these two liquids is mixed together, and 8 volumes of water added.

The glass is coated by placing a number of plates in a bath of liquid composed of 50 volumes of the silvering mixture, and 10 of the reducing mixture, to which 250 to 300 parts of water have been previously added.

In J. Loewe's process, 50 parts of sugar, prepared by being treated with dilute nitric acid, which is afterward neutralized by chalk, are dissolved in 5,000 parts distilled water, 20 parts pure fresh burnt lime are added, the solution is distilled, and kept in closely stopped vessels. In silvering, 6 parts of this liquid are mixed with 1 part of a solution composed of nitrate of silver (fused), 7; water, 150 to 160 parts; ammonia is then added until the precipitate formed is dissolved.

Several descriptions are given of the process of Petitjean of Paris. The following is from "Repertoire de Chimie Appliqué," Vol. I. p. 321: 100 grammes nitrate of silver are mixed with 62 grammes of ammoniacal liquid, specific gravity 870 to 880, and 500 grammes distilled water, and filtered. This solution is diluted with 15 times its bulk of distilled water, and 7½ grammes of tartaric acid dissolved in distilled water are added little by

little while the liquid is being strongly agitated. A similar liquid is prepared with twice the quantity of tartaric acid.

The first is applied by placing the glass plate, carefully cleansed, face downward, in a cast-iron trough, pouring and spreading the solution on the back to the thickness of $^1/_{10}$ inch, and raising the heat to 60° Cent.; when deposition has taken place, it is similarly treated with the second liquid, and afterward covered with a protecting varnish.

Delamotte's silvering liquid is prepared by dissolving 20 grammes gun-cotton and 100 of natron in 200 cubic centimeters of water; the liquid becomes warm and turns brown; when cold, it is diluted with water until it forms the bulk of a liter. With this is mixed a solution made by dissolving 100 parts nitrate of silver in 200 parts of water; 120 parts of this are mixed with an equal quantity of liquid ammonia; when the resulting precipitate is redissolved and the liquid becomes clear, it is mixed with the first solution, and after standing 12 hours, half the volume of distilled water is added, and the combined solution is ready for use.

It is poured on the plate, ledges coated with resinous varnish on the under side preventing it from running off, and subjected to a heat of 60° or 70° by a water bath, in which the face of the glass is immersed.

Masse employs 600 grammes citric acid dissolved in water, and neutralized by 320 grammes lime; the precipitate is mixed with 240 grammes sulphate of magnesia, in twice its weight of water, forming tartrate of magnesia in solution, which is filtered and evaporated in a porcelain dish to ⅔ its original volume; when cool, ammonia is added, and the liquid put away in closed vessels. For use, 100 grammes of oxide of silver are dissolved in 1 kilogramme of the above solution, three liters of water are added, and the whole is digested at a low heat.

A battery is employed for causing precipitation of the metallic silver on the article to be coated.

Nitrate of silver and alcoholic solution of tannin have been employed by Unger for silvering glass and porcelain.

Cimeg's process consists in moistening the cleansed glass with a solution of 1 part Rochelle salts (tartrate of soda and potassa) in 200 parts of water, and afterward pouring on it a solution containing nitrate of silver 20, Rochelle salts 40 parts, which is allowed to flow uniformly over the glass; the plate is then kept in a horizontal position for one half-hour, when it is washed: when dry, the silver is coated with a varnish composed of gum-dammar, 20 parts; asphaltum, 5; gutta-percha, 5; benzine, 75.

R. Bottger's process is based on those of Petitjean and Cimeg. He dissolves one drachm of nitrate of silver in an ounce of distilled water and pours this slowly into a boiling solution of tartrate of soda and potassa; a second liquid is prepared by dissolving one drachm nitrate of silver in one ounce of distilled water. These two solutions are mixed and applied to the glass, causing precipitation of the metal.

In the process of Martin four liquids are employed: —

1. 40 grammes nitrate of silver in 1 liter of water.
2. 70 cubic centimeters of ammonia of 24° in 1 liter of water.
3. 40 grammes caustic potash in 1 liter of water.

The above must be free from carbonic acid.

4. 25 grammes of sugar are dissolved in 250 grammes of water; 3 grammes of nitric acid are added. The liquid is boiled, allowed to cool, and sufficient of No. 3 to nearly neutralize the acid added; also 50 centimeters of alcohol, when it is diluted with water sufficient to bring its volume up to ½ liter.

Foucault's method is similar to the above, the proportions being somewhat varied and the nitrate of silver added last.

L. L. Hills dissolves 1 ounce nitrate of silver in 2 fluid ounces of water; liquid ammonia is added until the precipitate which at first forms is dissolved, care being taken to avoid excess of ammonia. A few grains of nitrate of silver, sufficient to cause a slight tarry odor, are then added; this odor indicates that the liquid is in proper condition for use. With this is mixed a compound of 5 gr. mannite, 1 dr. sulphuric ether, and 1 oz. sugar, treated with pure sulphuric acid and neutralized with pulverized chalk. It is applied to the glass in an india-rubber pan, heated by a water-bath at 212° Fah. temperature, a rocking motion being constantly maintained. A varnish composed of gum-dammar and sulphuric acid is preferred for covering the deposited silver.

Drayton proposed the use of essential oils, as oil of cassia, pink, etc., for separating silver from the ammoniacal solution. Resinous matters, produced by the oxidation of the oil, were found, however, to form spots on the silver surface.

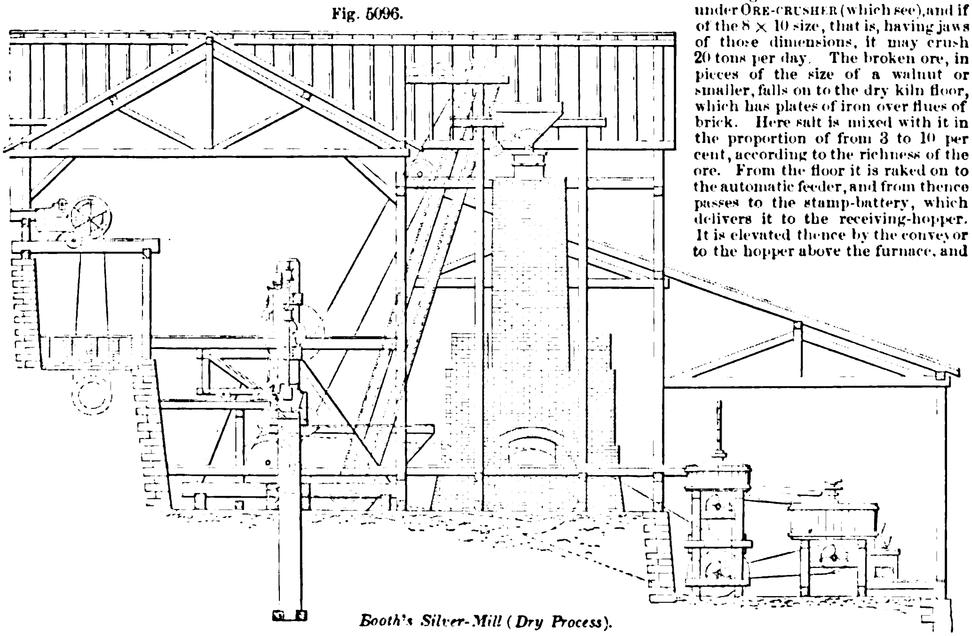
Wagner remarks that only those oils which contain aldehyde are adapted for silvering, and these must be freed from carbureted hydrogen. For this purpose oil of rue, for example, is agitated with a strong aqueous solution of double sulphite of potash. From the compound thus formed, the oil of rue is separated free from resinous matters by dilute sulphuric acid. The purified oil is dissolved in alcoholic ammoniacal liquid for precipitating the silver solution.

The process employed by R. Siemens, and described in the "Archiv der Pharmacie," is as follows: Aldehyde ammonia is first made by conducting dry ammonia gas through aldehyde. The aldehyde ammonia and the nitrate of silver are dissolved separately in distilled water, and the solutions mixed and filtered. The proportions used are, 4 grammes nitrate of silver, and 2.5 grammes aldehyde ammonia to one liter of water. The object to be silvered is first rinsed with a solution of sal-soda, then with alcohol, and lastly, with distilled water. When thoroughly clear, it is filled with the above solution and suspended in a water bath. The bath is heated gradually, and as soon as the temperature of 122° Fah. is reached, the silver mirror begins to form. Its formation is soon completed, at a temperature of about 130° to 140° Fah. At first, while the coating is thin, it looks black, but as it grows thicker it acquires more luster, and finally forms a beautiful silver surface. When this has taken place, the object is removed from the water bath, and its contents emptied out. It can now be rinsed out with distilled water and allowed to dry. See also GLASS-SILVERING, pages 982, 983.

Sil'ver-mill. A mill or set of machinery in which argentiferous ores are treated.

Fig. 5096 is a view of a silver-mill as arranged for working ores by the dry process. The ore is fed into the Blake crusher, which is shown at the upper portion and left-hand end of the building. This machine is described under ORE-CRUSHER (which see), and if of the 8 × 10 size, that is, having jaws of those dimensions, it may crush 20 tons per day. The broken ore, in pieces of the size of a walnut or smaller, falls on to the dry kiln floor, which has plates of iron over flues of brick. Here salt is mixed with it in the proportion of from 3 to 10 per cent, according to the richness of the ore. From the floor it is raked on to the automatic feeder, and from thence passes to the stamp-battery, which delivers it to the receiving-hopper. It is elevated thence by the conveyor to the hopper above the furnace, and

Fig. 5096.

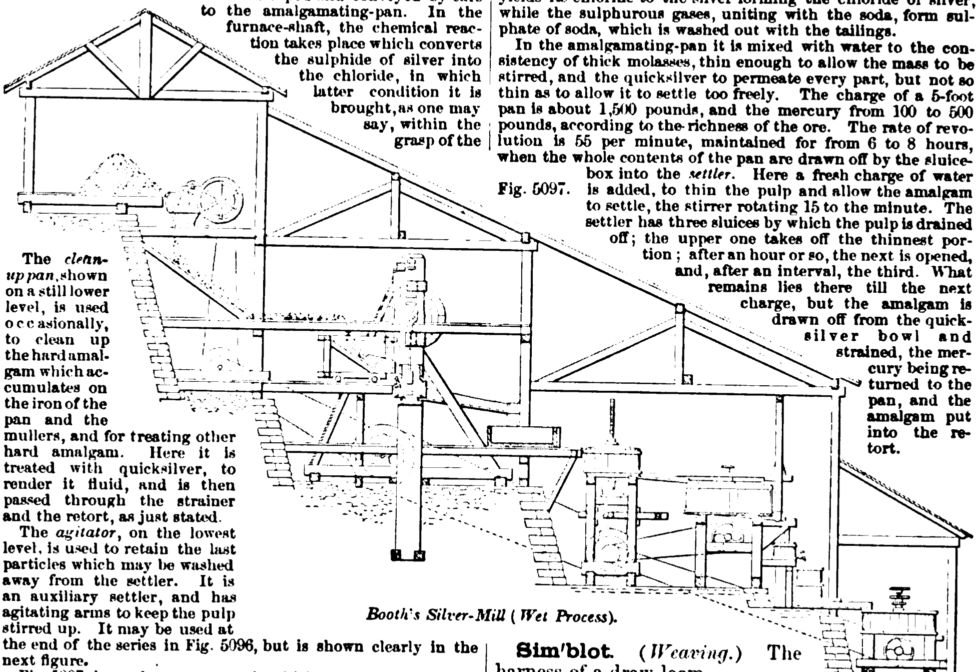


Booth's Silver-Mill (Dry Process).

is sifted down through the flame, being caught upon the furnace-bed, whence it is drawn about every hour on to the cooling-floor. Here it is damped and conveyed by cars to the amalgamating-pan. In the furnace-shaft, the chemical reaction takes place which converts the sulphide of silver into the chloride, in which latter condition it is brought, as one may say, within the grasp of the mercury. In the presence of the sulphurous gases from the sulphide of silver, the chloride of sodium is decomposed and yields its chlorine to the silver forming the chloride of silver, while the sulphurous gases, uniting with the soda, form sulphate of soda, which is washed out with the tailings.

In the amalgamating-pan it is mixed with water to the consistency of thick molasses, thin enough to allow the mass to be stirred, and the quicksilver to permeate every part, but not so thin as to allow it to settle too freely. The charge of a 5-foot pan is about 1,500 pounds, and the mercury from 100 to 500 pounds, according to the richness of the ore. The rate of revolution is 55 per minute, maintained for from 6 to 8 hours, when the whole contents of the pan are drawn off by the sluice-box into the *settler*. Here a fresh charge of water is added, to thin the pulp and allow the amalgam to settle, the stirrer rotating 15 to the minute. The settler has three sluices by which the pulp is drained off; the upper one takes off the thinnest portion; after an hour or so, the next is opened, and, after an interval, the third. What remains lies there till the next charge, but the amalgam is drawn off from the quicksilver bowl and strained, the mercury being returned to the pan, and the amalgam put into the retort.

Fig. 5097.



Booth's Silver-Mill (Wet Process).

The *clean-up pan*, shown on a still lower level, is used occasionally, to clean up the hard amalgam which accumulates on the iron of the pan and the mullers, and for treating other hard amalgam. Here it is treated with quicksilver, to render it fluid, and is then passed through the strainer and the retort, as just stated.

The *agitator*, on the lowest level, is used to retain the last particles which may be washed away from the settler. It is an auxiliary settler, and has agitating arms to keep the pulp stirred up. It may be used at the end of the series in Fig. 5096, but is shown clearly in the next figure.

Fig. 5097 shows the wet process, in which the dry-kiln floor and the Stetefeldt furnace are not used, the wet ore from the mines remaining wet throughout the whole process. The chemical changes for the reduction of the sulphide of silver to a salt of silver, upon which quicksilver will act, take place in the pan. The agents are chlorides of sodium or ammonia, sulphates of copper, iron, or ammonia. On the left, on the highest floor, is the Blake crusher, from which the broken ore falls on to a floor, and thence by a chute to the automatic feeder, which delivers it to the stamps. A sluice conducts the pulp to the *settler*, which is shown about midlength of the building. From this, the *slimes* are conducted by a sluice to the amalgamating-pan, where they are ground, as in the case of the dry process, excepting that in the former the duty of the mullers is principally to stir the pulp and keep it agitated, so that the quicksilver may come in contact with all of the silver. Below the *amalgamating-pan* are the *settler*, *clear-up pan*, and *agitator*, as previously described.

Sil'ver Pa'per. Paper covered with silver foil.

Sil'ver-plat'ing. See ELECTRO-PLATING; SILVERING, etc. See also Watts' "Electro-metallurgy."

Sil'ver-pow'der. For japanners, etc. Bismuth, 1; tin, 1; melted, and 1 part of mercury added. Cool, and powder.

Sil'ver Rain. (*Pyrotechny.*) Small cubes of a composition which emits a white light in burning; used as decorations for the pots of rockets, etc.

Sil'ver Sol'der. Hardest silver solder, 4 parts fine silver, 1 copper. Hard silver solder, 3 parts sterling silver, and 1 brass wire, added after melting the silver to avoid waste of zinc. Soft silver solder for general use, 2 parts fine silver, and 1 brass wire; occasionally $\frac{3}{4}$ part of arsenic is added, to render the solder more fusible and white, but it diminishes the malleability. The arsenic should be added at the last moment, and care taken to avoid its fumes.

Sil'ver-steel. An alloy of silver and steel, which seems to have been first made by Faraday and Stodart, about 1822, and which was soon taken up by the cuttlers of Sheffield for fine razors, surgical instruments, etc. The silver is only about the $\frac{1}{500}$ part.

Sim'blot. (*Weaving.*) The harness of a draw-loom.

Sim'i-lor. A gold-colored alloy of copper and zinc. See SEMILOR; ALLOY.

Sim'ple. (*Weaving.*) *a.* A draw-loom employed in fancy weaving.

b. A cord dependent from the tail of a harness cord in a draw-loom, having at its end a *bob*, by which it is pulled to work a certain portion of the harness.

Sinch (Spanish *cincho*, a girth). (*Harness.*) A strap whereby the loop on the end of the girth of a Spanish saddle is laced to the loop on the saddle. The Spaniards and Mexicans do not use a buckle, but pass a strap, rope, or raw-hide over and over around the loops, and tuck the end in.

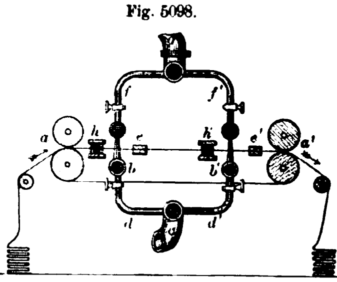
Sin'don. 1. (*Fabric.*) A fine East Indian cotton stuff.

2. (*Surgical.*) A pledget of lint introduced into the hole made by a trephine.

Singe'ing-ma-chine'. A machine in which the fibrous down is removed from the surface of cotton cloth by passing it through a gas flame.

In the longitudinal section (Fig. 5098), *a a'* are two pairs of wooden cylinders covered with fustian, between which the cloth is drawn and submitted to the action of a series of gas-jets

Fig. 5098.

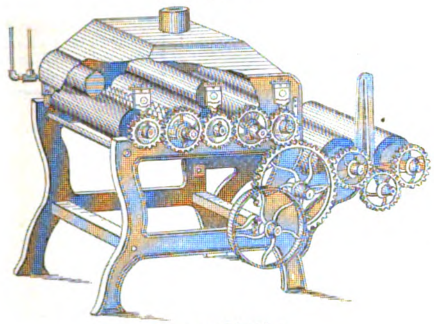


Singeing-Machine.

issuing from the pipes $b\ b'$ at distances of about one eighth of an inch apart. These are supplied from the main pipe c by the branches $d\ d'$ provided with cocks by which the flames from the jets are so regulated as to coalesce and form a continuous line of fire. Brushes $h\ h'$ remove the singed fiber, and any sparks occurring are extinguished by the blocks $e\ e'$. Above the cloth are two pipes $f\ f'$, each having a longitudinal slit at bottom and communicating with the large pipe g, which is exhausted by means of a fan.

Fig. 5099 shows Curtis and Marble's gas-singer for print-cloths and all other fabrics for bleaching and finishing. It has a Bunsen burner with fan-blower attached for supplying the air. It is made with from one to six sets of burners and a width to correspond to the shearing-machine.

Fig. 5099.



Singeing-Machine.

Singe'ing-lamp. A flat-bodied lamp with one open side to the light-chamber, used to singe the hair of horses as a substitute for clipping.

Sin'ger (*singe-r*). An apparatus through which cotton or woolen goods are passed to relieve them of their fluff, preparing them for the dyer. The capacity of a braid-singer is 10,000 yards per hour. See SINGEING-MACHINE.

Sing'ing-glass. A thin, sonorous glass vessel, which yields an echo when vibrated by a sound. It is referred to by Pepys in his Diary, 1669: "They are so thin that the very breath broke one or two of them." See Figs. 4059, 4270, 4271.

Sin'gle-act'ing En'gine. (*Steam-engine.*) An engine in which steam is admitted to one side only of the piston, in contradistinction to the *double-acting engine*, in which both motions of the piston are made by *live-steam*.

The Newcomen atmospheric engine is an example, and was the first successful steam-engine (see Fig. 406, page 177). This engine was working at the Cornish mines when Watt grasped the problem and made his engine (Fig. 406). See also Fig. 1467, and Plate XLIV. page 1829.

Steam is admitted below the piston, in order to displace air. The steam being condensed, the atmospheric pressure above the piston depresses the latter and elevates the other end of the walking-beam to which the pump-rod is attached.

In another form: —

Steam is admitted above the piston, to depress it and raise the pump-rod. The steam, being condensed, allows the weighted pump-rod to bear upon the column of water in the pump-stock, and the water is thereby *forced* up the eduction-pipe.

In another form: —

Steam is admitted above the piston, to depress it and raise the other end of the walking-beam to which the lift-rod of the pump is attached. In this instance, the steam stroke of the piston is the effective stroke of the pump-rod.

Watt was the inventor of the *double-acting steam-engine*. He placed a cover on the cylinder, and introduced steam to prevent the cooling of the cylinder by the access of air. He afterward used the steam above the piston, to give the positive downward motion, and thus originated the DOUBLE-ACTING STEAM-ENGINE (which see).

Sin'gle-block. A block having but a single sheave. A single sheave in a pair of cheeks.

Sin'gle-block Fur'nace. (*Metallurgy.*) An old form of iron-refining furnace.

Sin'gle-cut File. A file having but a single rank of teeth. A *float*. In contradistinction to the *double-cut* file, which has two crossing ranks of teeth.

The horizontal obliquity of the teeth, relatively to the central line of double-cut files, is about 55°, but in *single-cut* files the inclination is much less, and in some *floats* the teeth are square across the face of the file.

Fig. 5100.

Single-Cut File.

Sin'gle-flu'id Bat'ter-y. (*Electro-magnetism.*) A galvanic battery, having but a single fluid, in which the elements are submerged, or by which they are wetted. The original Voltaic pile was the first of this class. Cruikshank was the first to submerge the elements. Babbington and Wollaston had also submerged elements. See GRAVITY-BATTERY; CALLAUD-BATTERY.

The term is in contradistinction to the *double-fluid battery*, invented by Daniell.

Sin'gle-line. (*Saddlery.*) A single rein leading from the hand of the driver to a strap forked a little behind the hames, and proceeding thence to the bit-rings.

This is the favorite mode in most parts of the West of driving horses at work on the farm, or when hauling on the roads with more than a single span or pair. A steady pull brings the horse *haw*, or to the left, the *near* side; and a jerk turns him *gee*, or to the right, the *off* side. The *off* horse is fastened to the near one by a *jockey-stick* and a *hitch-back* strap. The former makes him keep his distance, and the latter keeps him from going too fast. The system was made familiar to many by its being introduced into the United States Army. The heavy six-mule teams of the transportation trains, especially those of the West, were thus driven. The driver rides the near wheel-horse, and the single line passes through a runner on the head-stall of the near horse of the middle pair and thence to the bit of the near leader. The off leader is *jockeyed off* by the stick which is attached to his bit and to the hame of the near leader. The middle pair of horses are on each side of the fifth chain, and have no choice but to submit and go with the others.

Sin'gle Mi'cro-scope. A microscope consisting of a single lens. Some of those on the principle of the Stanhope lens are very powerful.

Sin'gle-reed Plane. A bead-plane with but one hollow in its sole. Bead-planes are also made for planing several beads at once.

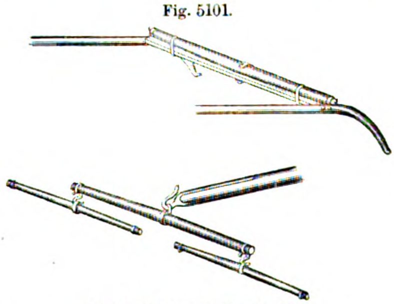
Sin'gles. (*Silk-manufacture.*) Silk thread formed of one of the reel-threads twisted.

Several singles are united, and twisted in a direction contrary to that of the *singles*, to make *thrown* silk.

Sin'gle-shov'el Plow. A corn-plow with but one shovel, in contradistinction to a double-shovel plow. See SHOVEL-PLOW, Fig. 5042.

Sin'gle-stick. (*Weapon.*) A long stick, formerly used in a certain description of fencing.

Fig. 5101.



Single-Trees and Double-Tree.

Sin'gle-tree. A bar secured by its center to the cross-bar of the thills or shafts, and to whose end the traces are attached. The single-trees are connected to the ends of the double-tree when the horses are hitched in pairs. A *whiffle-tree.*

Fig. 5102.

Single-Tree Hook.

Sin'gle-tree Hook. A hook on each arm of the single-tree, to which the traces are attached.

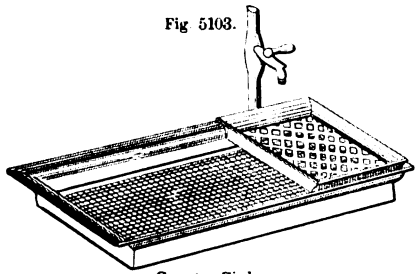
Sin'i-cal Quad'rant. (*Nautical.*) An instrument formerly used for working out courses and distances.

Sink. A tray into which slops or wash-water are poured, to get rid of them by means of a pipe which carries them to a drain.

Sinks are used in kitchens, wash-houses, bar-rooms, etc.

In Fig. 5103, the sink has near the bottom a grating, and its grooved sides furnish support to movable metallic baskets.

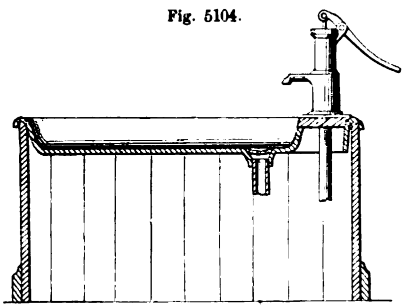
Fig 5103.



Counter-Sink.

In Fig. 5104, the sink-top is of cast-iron, rectangular outside and rounded within. It has a down-curved edge to receive the top of its supporting wooden frame, and an extension at one end to hold a wooden shelf for the support of a pump.

Fig. 5104.



Kitchen-Sink.

Sink'er. 1. (*Knitting-machine.*) A wheel with thin plates or projections, called *wings*, inclined to its axis and used to depress (sink) the yarn between the needles and below the beards.

A is a top view, and *B* an elevation of a knitting-machine, in which *a a* is the sinker, and *b b* the knocking-off wheel. The *sinker* depresses the yarn between the needles below the points of the beards. The *landing-wheel* raises the loops just above the points of the beards. The *knocking-over* wheel raises the loop over the head of the needle.

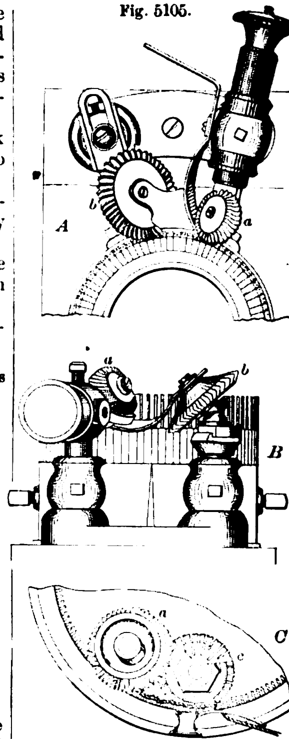
C is for a peculiar kind of machine in which a weft-thread is introduced. The wheel *c* is for pressing out every alternate needle, so that a yarn-carrier can lay in the weft-thread. The *sinker-wheel a* presses down the weft-yarn between the needles, and down on the loops already formed.

In the stocking-frame, the *jack-sinkers* and *lead-sinkers* alternate with each other. The jack-sinkers are suspended from the ends of the jacks, and are separately movable; the *lead-sinkers* are fixed to a bar called the *sinker-bar*, and all move together.

2. A leaden weight for a fishing line, net, or seine.

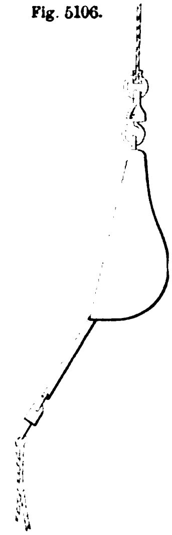
Sink'er-bar. A bar in a knitting-machine to which the *lead-sinkers* are attached.

Fig. 5105.



Sinker.

Fig. 5106.



Fish-Line Sinker.

Sink'er-wheel. (*Knitting-machine.*) One with a series of oblique wings to depress the yarn between the needles. See SINKER.

Sink'ing. 1. (*Joinery.*) A rabbet or angular recess in the corner of a board. See RABBET.

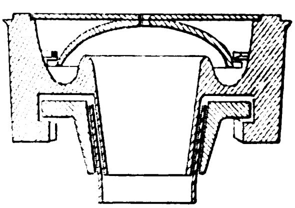
2. (*Mining.*) The digging of a vertical shaft from above downward.

A *rising* shaft is one excavated from below upward.

Sink'ing-head. (*Founding.*) The molten metal in the ingate of a mold to supply metal to the casting during shrinking.

Sink-trap. (*Hydraulics.*) A trap for a kitchen sink, so constructed as to allow water to pass down, but not allow reflow of air or gases.

Fig. 5107.



Sink-Trap.

Sin'net. Spun-yarn. Plaited hempen yarn or straw. *Sennet.*

Sin-um'bra-lamp. A form of astral lamp in which the exterior edge of the circular oil-vessel is beveled off at the top so that the rays of light proceeding from the wick reach the surface on which the lamp is supported at a less distance from the center than in the ordinary construction. The light is also diffused by a ground-glass shade surrounding the chimney, so that the shadow is rendered imperceptible. (*Sine umbra.*)

Si'phoid. (*Hydraulics.*) Soda-water apparatus.

Si'phon. 1. A curved tube having one branch longer than the other; used for transferring liquids from higher to lower levels. It acts by atmospheric pressure, and consequently cannot be depended on for overcoming hights greater than about 30 feet near the level of the sea, and a less hight at great elevations.

Siphons are shown in the Egyptian tombs of the dates of 1450 B. C. and 1355 B. C.

At *A*, in Fig. 5108, two men are engaged in mixing and decanting; wine probably. One is exhausting the air from a siphon preparatory to placing the lower end of the long leg in the vase into which the ends of two other siphons are already placed.

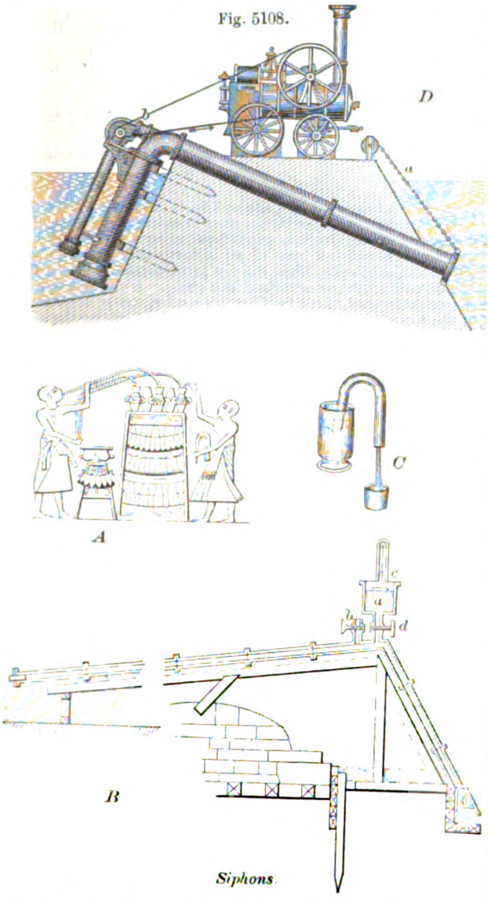
The siphon and its name are Greek. How much older than the Greeks as an intellectual nation, we know not.

It was a favorite contrivance with Hero of Alexandria, 150 B. C., in his various toys and automata, of which the cup of Tantalus is a favorite instance, and has been reproduced in modern times. See the "Spiritalia Heronis."

C shows the ordinary siphon; it is filled with liquid, the ends stopped, and the shorter leg immersed in the vessel from which the liquid is to be drawn; the longer leg being placed in or over the receiving vessel. On opening the ends a continuous flow is maintained until the level of the liquid in the upper vessel reaches that of the orifice in the shorter leg of the siphon.

B shows a large siphon used at Metz, in repairing a dike on the Moselle. To put it in operation, the ends were stopped with

Fig. 5108.



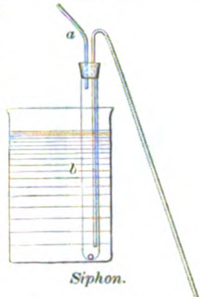
Siphons.

plugs and the siphon filled with water through a funnel *a*, the air being permitted to escape through the cock *b*. When full of water, this was closed with a cover *c*, provided with a tubular glass top, which permitted a view of an indicator-needle on a float, which showed at what hight the water stood as its level became gradually lowered in consequence of the air contained in the water accumulating at the bend of the tube. When the siphon required refilling from this cause, the cock *d* was closed, the cover removed, and the funnel filled with water, after which the cover was replaced and the cock *d* reopened. The flow was thus rendered continuous.

Gwynne's drainage siphon, *D*, is of ordinary construction, but has a flap-valve, opening inward or upward, attached to the inner end, which prevents the water flowing back again. At the other end of the siphon another valve is fixed, which opens outward, and is closed by the chain *a*. Attached to the siphon is a centrifugal pump, having a separate suction-pipe and valve dipping into the water, and its discharge-pipe *b* secured to and emptying into the siphon. To start the siphon, the pump is put in motion by the portable engine, the air-cock is opened, and as the siphon fills with water, all the air is quickly displaced. The air-valve is then closed, and on the chain *a* being unfastened, the outer valve will open, and the siphon will discharge water in the usual way and at the ordinary velocity. By keeping the pump at work, however, an increased discharge of water is obtained through the siphon, in proportion to the velocity with which the water is discharged by the pump.

By the arrangement shown in Fig. 5109, a siphon may be filled without danger of the liquid being brought in contact with the mouth or hands. It and the tube *a* are passed through the stopper of the tube *b*, which has an aperture at bottom provided with a ball-valve; on blowing through the tube *a*, the aperture is closed by the ball, the liquid is forced upward through the short leg of the siphon, and when the flow is established, the mouth is withdrawn, and the ball, ceasing to close the aperture, allows the liquid in the vessel to run freely into the tube.

Fig. 5109.



Siphon.

The term siphon has been employed with some impropriety to bent tubes used for conducting water from one hill to another across an intervening valley. An instance of these is found in the old Roman Aqueduct at Lyons (Fig. 290, page 129). See AQUEDUCT; SOUTERAZICI.

One of the largest siphons of this kind in the world is that of the iron pipe which conducts the water under Feather River, California. It has a vertical depression of 856 feet. The receiving arm has a head of 180 feet; the length of the inverted siphon is 2½ miles; its diameter 30 inches. It supplies the Spring Valley Mining and Canal Company, Cherokee Flat, Butte County, California.

The Bedonal siphon of the Madrid Aqueduct is an inverted siphon for crossing a valley, and is 4,600 feet in length. It consists of 4 cast-iron pipes, each 3 feet in diameter, and laid parallel.

It forms one portion of the chain of works which brings the water of the river Lozoya to Madrid. At the point where the river emerges from the Guadarama Mountains a cut stone dam 98 feet high is erected, its wings abutting against the rocks on each side of the ravine. This artificial lake contains 100,000,000 cubic feet of water. It was constructed under the supervision of Lucio del Vallé, and is 47 miles in length. The transverse section of the canal is about 20 square feet, and it discharges 6,600,000 cubic feet of water per day. Its cost was 57,897,368 francs, and it was built between the years 1851 and 1858. It has 31 tunnels, 32 aqueducts, and 3 large siphons for crossing valleys. See "Scientific American," November 13, 1869.

2. A bottle for dispensing aërated liquids, having a spring faucet and a discharge-pipe, which reaches nearly to the bottom of the bottle. See SIPHON-BOTTLE.

Si′phon-ba-rom′e-ter. An instrument consisting of a tube doubled upon itself twice and nearly filled with mercury. It is used as a manometer in showing the dilatations of the air in the receiver of an air-pump.

Fig. 5110.

Siphon-Bottle.

Si′phon-bot′tle. A flask for containing aërated waters, which may be discharged without uncorking. The bent tube *a* is provided with a downwardly opening valve operated by the lever *b*, and kept to its seat by pressure of the contained gas, which, when the valve is displaced by pressure on the lever, forces out the liquid until all is discharged.

Si′phon-cup. (*Machinery.*) A form of lubricator in which the oil is led over the edge of the vessel by capillary action, ascending and descending in a cotton wick and dropping on the journal.

Si′phon-fill′ing Ap′pa-ra′tus. An apparatus for filling siphon-bottles with aërated liquids.

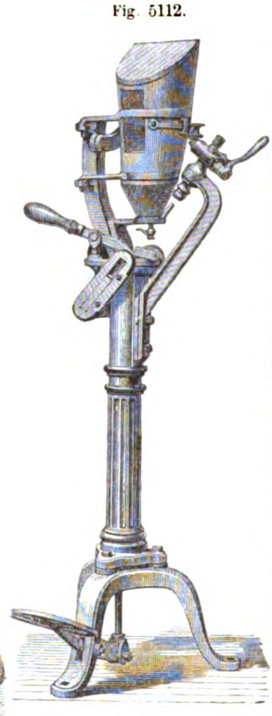
In Matthews' (Fig. 5111), the bottle is placed in the holder at the head of the machine, and inclosed by a rocking screen to protect the operator in case of explosion of the siphon. By pressure on the treadle, the bottle is elevated, the spout of the siphon is inserted into the filling-head, and the siphon-lever is

pressed so as to open the siphon-valve; the lever of the filling-head is then drawn toward the operator, causing the aërated water to fill the bottle. By reversing the movement of this lever the aërated liquid is shut off, and a vent-valve opened, by which some of the gas compressed above the liquid in the bottle is allowed to escape, so that more of the aërated liquid may enter the bottle when the liquid-valve is opened.

In Fig. 5112, the bottle is placed in a vertical position, and, by means of the foot-lever, is moved upon the inclined guides,

Fig. 5111.

Fig. 5112.



Matthews' Siphon-Filling Apparatus.

so that the spout of the siphon is caused to enter the filling-head, a three-way cock provided with a packing to receive the siphon-spout. The siphon-valve is opened by pressing on the hand-lever (on the left), and the siphon is filled by operating the three-way cock, which alternately permits liquid to enter the siphon and surplus of gas to escape from it to facilitate the filling. The swinging screen, when latched in position, protects the operator.

Si′phon-gage. A bent glass tube partially filled with mercury, used for ascertaining the degree of exhaustion effected by an air-pump.

Si′phon Re-cord′ing-tel′e-graph. An invention of Sir William Thomson. It is used at Duxbury for recording in the Morse alphabet the signals of the French Atlantic Cable. A light tube or perforated needle or a bristle dipping into an ink-reservoir is connected directly or by a thread to the device moved by the received current, and is caused to eject a thin stream of liquid at each pulsation of the current. The marking device or the paper is caused to vibrate, so as to produce the marks either by direct electrical or pneumatic action.

In the former case, the paper is drawn over a metallic plate electrified either positively or negatively; the tube being oppositely electrified, a difference of potential is maintained sufficient to create a tendency to cause a discharge as they approach each other, and to eject at each impulse a minute quantity of the liquid, proportioned to the length of the pulsation.

It has been found most convenient in practice to cause the paper to move in a vertical plane, and to use a small glass siphon with its short leg dipping in the ink, and the long leg pointing downward in close proximity to the paper. It is connected with a coil of fine wire suspended between the poles of a horseshoe-magnet. The deflections of the coil to the right or left by the passage of a positive or negative current of the line wire causes the siphon to leave a record on the paper strip, forming, apparently, a zigzag line, but in reality made up of a series of dots and dashes, which indicate the letters of the alphabet, after the manner of the Wheatstone system.

Si′ren. An instrument for producing musical tones and for measuring the number of sound waves or vibrations per second which produce a note of given pitch. The production of these tympanic shocks by puffs of air was first realized by Dr. Robinson, and his device was the first and simplest form of the siren. A stop-cock was so constructed that it opened and shut the passage of a pipe 720 times in a second. Air from the wind-chest of an organ being allowed to pass along the pipe during the rotation of the cock, a musical sound was smoothly uttered.

It was much improved by Cagniard de la Tour in 1827, who gave it its present name, and it has since been improved by Opelt, Seebeck, and Dové. In its original form it consists of a cylindrical box, into which a blast of air is introduced through an aperture in the bottom, while the top is perforated by a series of equidistant apertures arranged in a circle. A circular plate, similarly perforated, turns freely on its center, nearly in contact with the top of the box, alternately opening and closing the air-passages in the latter. The apertures are so inclined as to most effectually impart a rotary motion to the disk; and when air under pressure is admitted to the box, its escape through these apertures produces musical tones rising in pitch according to the velocity of the disk's rotation. The axis of the disk carries a screw-thread, operating a set of toothed wheels, by means of which the number of revolutions made in a given time is shown on a series of dials. This may be thrown in and out of gear. When it is desired to ascertain the number of impulses per second required to produce a note of given pitch, the wind pressure must be maintained at a uniform degree. The recording apparatus is thrown into gear and allowed to run for a given time; when it is detached, the register indicates the number of revolutions of the disk, which, multiplied by the number of perforations, gives the total number of impulses; this being divided by the number of seconds during which the observation was made, shows the number of vibrations or sound-waves per second corresponding to the given pitch.

In the siren of Seebeck the rotation is produced by mechanism, and not by the blast.

The double siren of Helmholtz consists of two sirens, one placed in inverted position over the other. The upper one may be rotated on its axis, while the instrument is in operation, by means of a crank. This instrument is adapted for the investigation of the interferences of unequal sound-waves, of combination tones, and many other acoustic phenomena.

Fig. 5113.

Siren.

In its most elementary form the siren is simply a perforated rotating disk, against which a current of air is directed, producing sounds of higher or lower pitch, according to the velocity of rotation. The limits of audible sound are the rates of vibration of 16 and 38,000 in a second, which embrace more than 11 octaves; but the range of effective musical sounds is much less. The sounds used in music are almost never lower than 32 vibrations in a second (the lowest C on the piano-forte), thus comprising seven octaves.

From the deep, piercing nature of the sound which the siren emits, it is well adapted for fog signals or alarms. In this case two disks rotating with great velocity in opposite directions are employed. They are driven by a steam-engine, which also forces a blast of steam through their apertures, when those in the two disks come in apposition. The device is placed at the smaller extremity of a large trumpet, which intensifies the sound. The rate of rotation of the disks is about 1,000 per minute, and the cost of the device is about $ 3,500.

The doctrine of the different sounds of vibrating strings of different lengths, and the communication of sounds to the ear by the vibration of the atmosphere, is ascribed to Pythagoras, about 500 B. C.; mentioned by Aristotle, 300 B. C.; explained by Galileo, A. D. 1600; investigated by Newton, 1700.

"Discoursed with Mr. Hooke about the nature of sounds, and he did make me understand the nature of musical sounds made

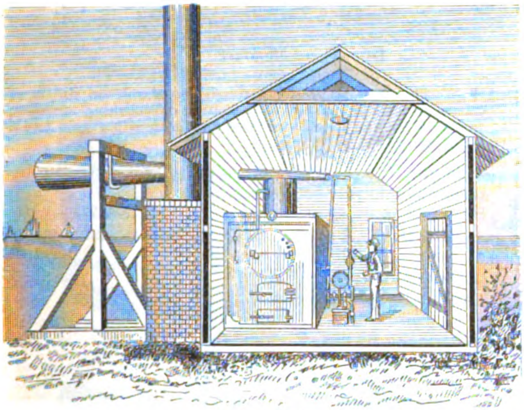
by strings, mighty prettily; and told me that having come to a certain number of vibrations proper to make any tone, he is able to tell how many strokes a fly makes with her wings, by the note that it answers to in musique. This I suppose is a little too much refined; but his discourse in general of sound was mighty fine." — PEPYS' *Diary*, 1668.

It has been ascertained by means of the siren that the wings of the mosquito move at the rate of 15,000 times a second.

An ingenious method of registering the vibrations of the wings of insects was adopted by E. J. Marey, and is described in the "Comptes Rendus."

The author of the article sought for a mode of exhibiting, in an unmistakable manner, each of the beats of the wing of an insect, and the graphic method answers very well for determining their frequency.

Fig. 5114.

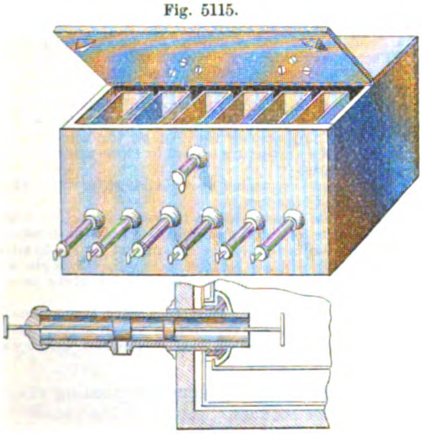


Steam-Siren.

He grasped, with a fine pair of nippers, the hind part of the abdomen of an insect, and when it sought to fly, directed one of its wings in such a way that it rubbed by its point against the surface of a smoked cylinder, which revolved with a known velocity. The wing, at each of these revolutions, carried away a little of the black of the smoke which covered the cylinder, and left a trace of its passage. This experiment gives a diagram exhibiting the varied forms that are periodically reproduced with the same characteristics, and, consequently, correspond to one revolution of the wing. By means of a chronographic diapason, the exact number of the revolutions of the wing which are effected in a second were precisely determined. That which he used gave a graphic delineation of five hundred simple vibrations per second.

A continual rubbing of the wing on the cylinder presents a resistance to this organ, which retards its frequency; so in order to have the nearest approach to the truth, those drawings were selected in which the contact of the wing with the cylinder was at a minimum, so that the diagrams were reduced to a series of points. The following results were obtained: Common fly, 330; drone, 240; bee, 190; wasp, 110; hawk-moth, 72; dragon-fly, 28; cabbage-butterfly, 9.

Fig. 5115.



Sirup-Stand.

Experiments with the *siren* show that the extreme limits of the human voice in males vary from 384 to 1,266 vibrations per second, and in females from 1,152 to 3,240. The highest note in music is about the 14th C (five octaves above the middle C of the piano-forte), and this is due to 8,192 vibrations per second; but much higher tones can still be heard. Savart has produced tones due to 48,000 vibrations per second.

Sir′up-stand. An attachment to a soda-water apparatus, to supply the tumblers with sirups. Some have faucets connecting with the separate sirup reservoirs; others have pistons acting as miniature pumps. In the example, the case has a hinged cover, kept in place by projections, and contains earthen sirup-jars and a cooling-chamber for the soda-water, each surrounded by ice. The sirup-faucets are lined with glass, and secured to the jars by a screw and rubber packing.

Sis′ter-block. (*Nautical.*) A kind of double block which has two sheave-holes, one above the other; a score at each end, and one between the sheaves. It is used as a topsail-lift and reef-tackle block, and is hollowed out on each side of the shell, so as to lay between the shrouds. The name is from *cithern*, signifying its *fiddle* shape.

Fig. 5116.

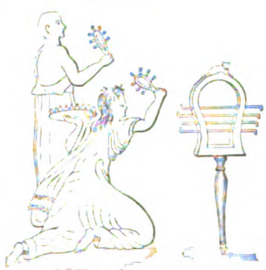
Sister-Block.

Sis′ter-hook. A double hook in which the shanks of the respective portions form *mousings* for the fellow portions. A *match-hook*. See MOUSING-HOOK.

Sis′ter-keel′son. (*Shipbuilding.*) An additional keelson secured on each side of and parallel to the main keelson. The sister-keelsons are bolted to the floor-timbers. A *side keelson*.

Sis′trum. (*Music.*) A jingling instrument of ancient Egypt. It had four loose rods in a lyre-shaped metallic head. It was, in fact, a rattle made of bronze or silver, according to ability. It was used in the services of Isis or Athor, which were introduced into Rome before the Christian era. It is still used in Christian churches in Nubia and Abyssinia.

Fig. 5117.



Sistrum.

Sitz-bath. A hip-bath in which a person assumes a sitting posture.

Six-shoot′er. (*Weapon.*) A colloquial name for the six-chambered revolver.

Size. 1. A gelatinous solution made by boiling the skin and membraneous tissues of animals to a jelly.

The finest is made in Russia from the sounds and air-bladders of sturgeon, and is called *isinglass*.

A coarser quality is made from scraps and clippings of hides, hoofs, horns, etc., and the jelly or size resulting is molded, cut into flakes, and dried, forming glue.

A quality made from clean scraps of the above-mentioned material is sold as isinglass, which it nearly resembles.

Bones and feet of animals also yield a glutinous, viscid solution or jelly, which may be considered a size.

Size is used in calico-printing, paper-making, paper-hanging, bookbinding, whitewashing, painting, gilding, and in other arts and trades.

In some cases, it stands in the place of or is used interchangeably with *dextrine* or British gum, paste, starch, gum-water, varnish, or other viscid solution, whose particles become hard when their water of solution evaporates.

The sizes used in gilding are as follows: *gold-size* for *oil-gilding*, linseed-oil or fat oil and ocher.

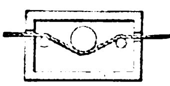
That used for *burnish-gilding* is composed of pipe-clay, red chalk, black-lead, suet, bullock's blood, brought to a proper consistence by a solution of gelatine.

Bookbinder's size is a fine glue made of parchment shavings. Another material used by the gilder is *glaire*, white of egg.

2. A gage for measuring. An instrument for measuring pearls. A number of perforated gages are fastened together by a rivet at one end.

Size-box. (*Rope-making.*) One through which cordage is drawn in the process of sizing. The cordage having been drawn through the size-box and partially dried is drawn slowly between closely pressing reciprocating *rubbers* and *snuggers*, which are stationary relatively to the slowly moving carriage to which they are attached. The size is flour-paste mixed with other ingredients, and the operation on the rope is called *snugging, slicking*, or *finishing*. It smooths down the *sleezy* and *fuzzy* fibers of the twisted rope.

Fig. 5118.



Size-Box.

Si'zel. (*Coining.*) Strips of metal from which planchets have been removed. *Scissel.*

Siz'er. 1. A machine of perforated plates to sort articles of varying sizes, as the *coffee-sizers* of Ceylon and Rio.

2. A gage, as the *bullet-sizer*, which has holes to determine the sizes of bullets. See also SHELL-GAGE.

Size-stick. The shoemaker's measuring-stick to determine the length of feet.

Siz'ing. A glue or paste used in manufactures. See SIZE.

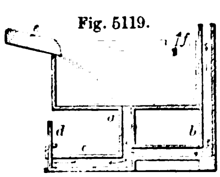
Siz'ing-ap'pa-ra'tus. (*Mining.*) Machinery for sorting ore into grades according to size, for treatment by the appropriate means.

Hand-sieves, swing-sieves, and *shaking* and *cylindrical riddles* are the usual means employed.

Jigging-sieves are not for sizing, but for sorting by gravity. See JIGGER.

Siz'ing-cis'tern. A form of ore-separator which acts upon the metalliferous slime from the stamping-mill.

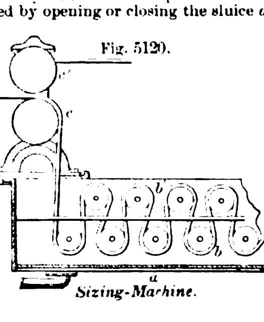
Fig. 5119.



Sizing-Cistern.

It consists of a wooden box, having an opening *a* at the bottom, which communicates with a pressure-pipe *b* and an outlet *c* provided with a small regulating sluice *d*. The lighter stuff from the buddles *e* is carried upward and conducted off by the opening *f*, while the heavier descends. The strength of the upward current, and consequently the quantity and size of the particles conveyed away at *f*, is regulated by opening or closing the sluice *d*.

Fig. 5120.



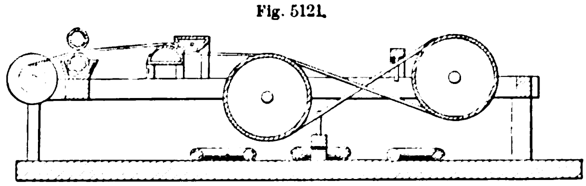
Sizing-Machine.

Siz'ing-ma-chine'. An apparatus for sizing cotton warp-threads.

The trough *a* is provided with a steam jacket, and contains a number of rollers *b b'*, etc.; it is nearly filled with liquid paste, and the warp is drawn alternately under one and over another of the rollers until it passes between the rolls *c c'*, which express the superfluous paste. For woolen, a sizing of glue is employed. The yarn is drawn backward and forward through trumpet-shaped openings, and passes beneath a roller at each end of the box; repeated compression and immersion is necessary to expel the air and saturate the fiber.

Fig. 5121 is a machine for sizing and finishing covered skirt-

Fig. 5121.

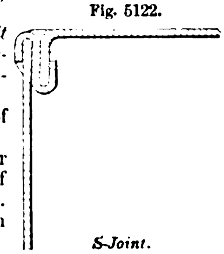


Wire-Sizing Machine.

wire. The wire is passed through the starch or size, and thence directly in contact with ironers or polishing surfaces, whence it may be passed over rolls and heaters previous to its being reeled.

S-joint. A mode of joining two surfaces by means of a doubly bent strip, S-shaped in cross-section.

Fig. 5122.



S-Joint.

Skain. 1. A shaved *split* of osier. A split is a quarter of the osier, divided longitudinally down the pith.

2. (*Spinning.*) A knot of yarn. See SKEIN, 1.

3. (*Vehicle.*) A strap or tube of metal on the arm of a wagon-axle. See SKEIN, 2.

4. (*Weapon.*) An Irish short-sword. A *skean.*

Skate. 1. A runner fastened to the boot-sole, by which a person may propel himself upon the ice.

2. In an in-door sport suggested by skating, the sole has rollers instead of a runner. A *parlor-skate.*

Fitz-Stephen informs us that it was customary for the English, in the thirteenth century, to amuse themselves on the ice by fastening bones of animals to the soles and pushing themselves forward by means of a stick, shod with an iron spike. Wooden skates, shod with iron and steel, were introduced into England from the Netherlands, about 1650.

"It being a great frost, did see people sliding with their skeates, which is a very pretty art." — PEPYS' *Diary*, November, 1662.

Fig. 5123 illustrates various recent patterns of skates, with their modes of attachment to the shoe.

a may be arranged so as to be secured either by clamps or straps.

b is secured by adjustable clamps.

c is fastened at the heel by three spurs, adjustable by a screw, a strap being employed for the front.

d by a lip at the toe, and a clamp, moved backward or forward by a screw, at the heel.

e has toe and heel clamps, which are caused to approach or recede by a screw.

f, the skate-iron is pivoted and provided with a spring, so that the heel and toe clamps are opened by releasing and depressing the iron; by placing the foot on the sole-plate and raising the iron, the clamps are caused to close upon the shoe and secure the skate.

g has two runners, connected by a flexible strip, which yields to the movements of the foot.

h is a parlor-skate constructed on the same plan.

i is a parlor-skate in which the rollers are fastened in hangers beneath the sole; runners may be substituted for the hangers.

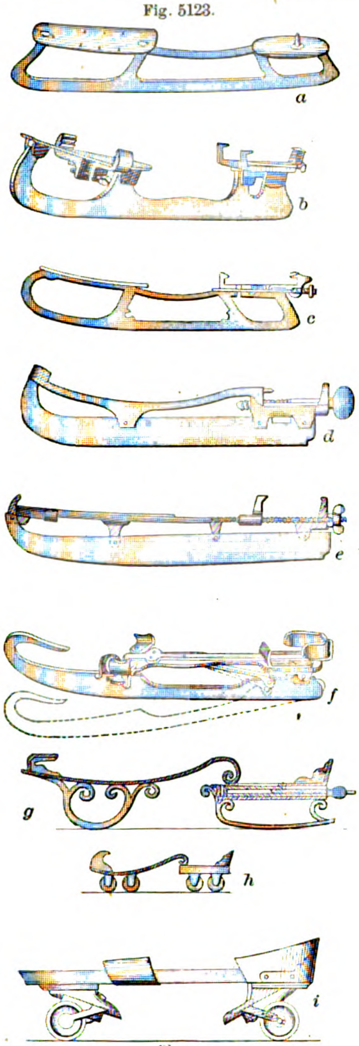
The skate (*a*, Fig. 5124) is secured to the boot by a pin with pointed enlarged end in the heel-plate, and a strap passing through the sole-plate and over the foot.

In *b* both the heel and sole plates are divided longitudinally, one of each being hinged; the clamps are adjustable to the width of the foot, and are, when fixed to the boot, held by the pressure.

Skate-grinder. A machine for grinding skates, straight-edged or rockers.

The loose skate-holder and the table have each a plane or bevel-bearing surface, forming, when resting on each other, two corresponding plane or bevel surfaces. The rotary grinding-wheel dresses the running edge of the blade. The holder is

Fig. 5123.

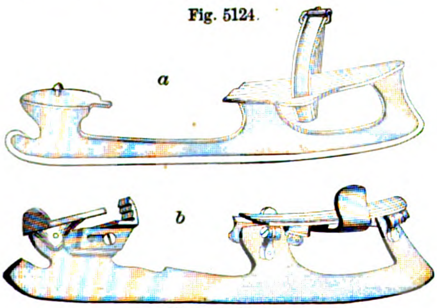


Skates.

attached with adjustable clamps, and has rests for securing the work.

Skean (Irish, *Scian*). (*Weapon.*) An Irish

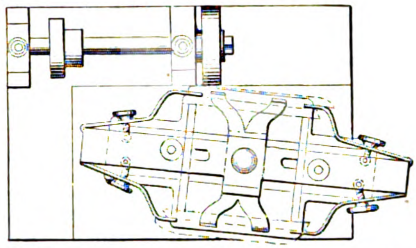
Fig. 5124.



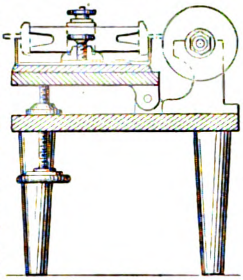
Florence Skates.

weapon. A large knife molded like a sword. A *skain.*

Fig. 5125.



Skeet. (*Nautical.*) A scoop used for throwing water on the sails and decks.



Skate-Grinder.

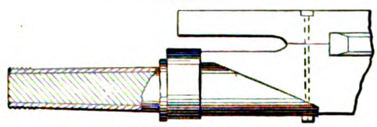
Skeg. (*Boat-building.*) A knee which unites and braces the stern-post and keel of a boat.

Skein. 1. (*Spinning.*) A quantity of yarn from the reel, of silk, wool, cotton, or flax. Of cotton it contains 80 threads of 54 inches ; 17 *skeins* make a *hank ;* 18 *hanks* a *spindle* (English). See also HANK.

The word *skein* is derived from the Greek word σχοῖνος, a *rope* or a *rush ;* indicating the material from which the ropes of Egypt were formerly made.

2. (*Vehicle.*) A metallic strengthening band or thimble on the wooden arm of an axle.

Fig. 5126.



Thimble-Skein.

The ordinary *skein* consists of three straps, let into slots in the arm.

The *thimble-skein* is a conical metallic sheath which envelops the wooden arm, and has a flanged nut on the end to hold the wheel on the arm. See AXLE.

Skel'e-ton-frame. (*Spinning.*) A kind of frame in which the usual can is replaced by a skeleton.

Skel'e-ton-key. A key of skeleton form, a large portion of the web being removed to adapt it to avoid the wards and impediments in a lock. See MASTER-KEY.

Skel'e-ton-plow. (*Agriculture.*) A plow in which the parts bearing against the soil are made in skeleton form to lessen friction. See PLOW.

Skelp. A strip of iron which is bent and welded into a tube to form a gun-barrel, or pipe.

Skelps for gun-barrels were formerly forged, the strip being about 3 feet long and 4 inches wide, thicker at the end for the butt than at the end which forms the muzzle. These *skelps* were afterward bent, lapped at the edges, and welded at several heats.

These forging operations were superseded some years since at Birmingham, England, by rolling processes, which have become general.

For rolling, the circumference of the roller is equal to the length of the skelp, and the shape of the groove is adapted in width and depth to the width and thickness of the skelp.

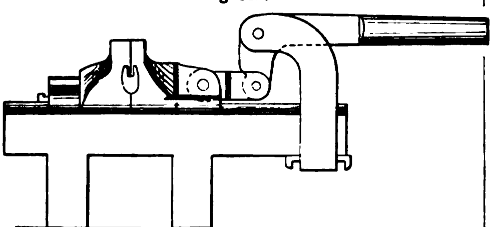
Welding was performed by running the skelp with lapping edges through the circular aperture formed by the semicircular grooves of adjacent rollers. The skelp was brought to a welding heat and placed on a mandrel.

This plan has been modified by making a blank of an extra thickness and combining a drawing and welding action.

A bar of iron about a foot long is bent into a cylindrical shape, the edges overlapping; being raised to a welding heat, it is then slipped over a triblet and passed between a pair of rollers, which weld the edges and draw the cylinder to the length and proportions of a gun-barrel at a single heat.

Skelp-bend′er. A die of required form is made in two parts, so arranged on a slide as to open for the admission of the end of the sheet and be closed

Fig. 5127



Skelp-Bending Machine.

by a lever. The end is then bent up, when it is seized by the proper apparatus and drawn through the die.

Skene-arch. (*Architecture.*) A segmental arch having a curve not exceeding 180°.

Skep. (*Husbandry.*) *a.* A farmer's basket for gathering corn or roots.

b. A beehive; a *gum.*

Skew. A term applied to an arch, vault, or bridge in which the front of the arch is oblique with the face of the abutment, instead of being at right angles thereto.

As originally built, the voussoirs were laid parallel to the abutments. In 1787, Chapman, in constructing a bridge over the Kildare Canal, was led to the invention of the correct principle, making the joints of the voussoirs rectangular with the face of the arch instead of being parallel with the abutments.

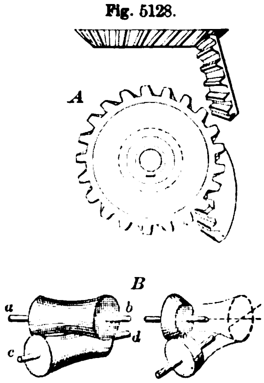
Skew-arch. (*Architecture.*) One having its faces oblique to the piers or abutments.

Skew-back. (*Architecture.*) *a.* The upper course of an abutment which receives the spring of an arch. An *impost.*

b. A bedding-stone.

Skew-bev′el Wheel. (*Machinery.*) A form of wheel employed to transmit a uniform velocity ratio between two axes which are neither parallel nor intersecting. The pitch surface of a skew-bevel wheel is a frustum or zone of a hyperboloid of revolution. In one of the figures (*B*), a pair of large portions of such hyperboloids are shown rotating about axes *a b c d.* In the other figure are shown a pair of narrow zones of the same figures, such as are employed in practice.

Fig. 5128.



Skew-Gearing and Skew-Bevel Wheels.

Skew-bridge. (*Architecture.*) One having an oblique arch or arches with spiral courses.

Skew-chis′el. 1. A chisel for wood working or turning, having the basil on both sides and an oblique edge.

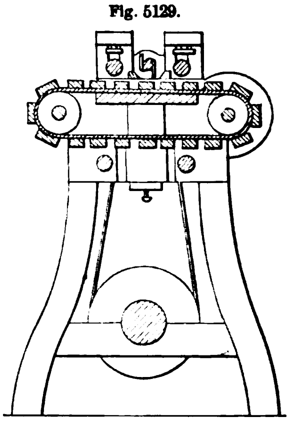
2. A carver's chisel, whose shank is bent to allow the edge to reach a sunken surface.

Skew′er. 1. (*Fiber.*) A bobbin-spindle fixed by its blunt end into a shelf or bar in the creel.

2. A spindle-shaped piece of wood inserted into meat, to hold the layers of muscle or muscle and fat together.

Skew′er-ma-chine′. The blocks are sawed into little slabs of the size and double the length of the skewer desired. They are then passed through a machine, which shapes them into little cylinders, looking like unpointed lead-pencils. The machine has a grooved endless floor-feeder, and a revolving grooved feed-roller and cutters, which are shaped to cut the cylindrical shape of the skewer. They are now ready for sharpening.

Fig. 5129.



Skewer-Machine.

Fig. 5130 is a machine to point, cut to a length, and count the skewers after they have been made round. The sticks, of double skewer-length, are fed from a hopper into a grooved cylinder, which presents them to a revolving cutter that points each stick, and cuts in two at the center, and at the same time is cut to a length by two revolving saws on the same shaft with the cutter. Not

Fig. 5130.

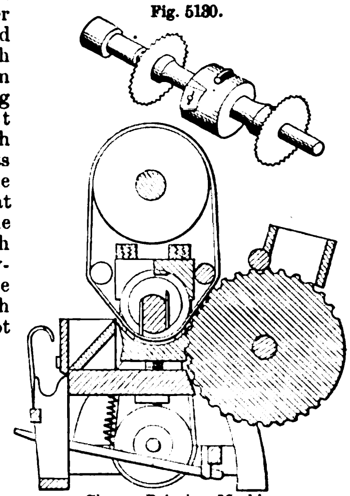


Fig. 5131.

Skew-Gearing.

Skewer-Pointing Machine.

until fifty are completed does the machine drop them into the pan below, from whence the bunches are taken and deposited in a tray preparatory to their transfer to the drying-room, the skewers being made from unseasoned wood.

Skew-gear′ing. Cog-wheels with teeth placed obliquely, so as to slide into each other and avoid clashing. They serve to transmit motion from one shaft to another when the two form an angle, but would not intersect if prolonged. *A*, Fig. 5128, SKEW-BEVEL WHEEL.

Skew′ing. (*Gilding.*) The process of removing superfluous leaf from portions of a surface and patching pieces upon spots where it has not adhered. It is performed by means of a brush and precedes burnishing. See GILDING.

Skew-plane. (*Joinery.*) One in which the

mouth of the plane and the edge of the iron are obliquely across the face.

Skew-rab'bet Plane. (*Joinery.*) A plane for cutting rabbets; the edge of the bit obliquely across the sole of the plane.

Skew-wheel. See SKEW-BEVEL WHEEL.

Skid. 1. (*Nautical.*) *a.* A strut or post to sustain a beam or deck, or to throw the weight of a heavy object upon a part of the structure able to bear the burden.

b. A pair of timbers in the waist, to support the larger boats when aboard.

c. Timbers acting as fenders against a ship's side when raising or lowering heavy bodies inboard or overboard.

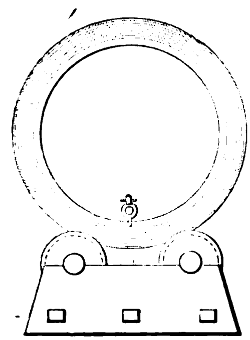
2. Slanting timbers forming an inclined plane in loading or unloading heavy articles from a truck or wagon.

3. Timbers resting on blocks on which a structure is built, such as a boat.

4. (*Ordnance.*) An oaken timber 6 feet long by 8 inches square, used for the temporary support of a cannon. These and the other implements are all made to given sizes with reference to their more convenient use and transportation together.

Skids of cast-iron are used for supporting cannon in store at the arsenals.

Fig. 5132.



Barrel-Skid.

5. A chain with a shoe to drag a wheel.

6. A log, forming a track for a heavy moving object.

7. (*Crane.*) An iron brake-piece.

8. A pair of parallel timbers for supporting a barrel, a row of casks, etc.

Skiff. (*Nautical.*) A small flat-bottomed boat, usually without a keel. In some parts of the United States, as the waters of the Chesapeake, the term is particularly applied to a small boat of this description, sharp at both ends, generally having a center-board, and provided with a small triangular sail.

Skif'fling. (*Masonry.*) *Knobbing.* Knocking off the rough corners of ashlar in the preliminary dressing.

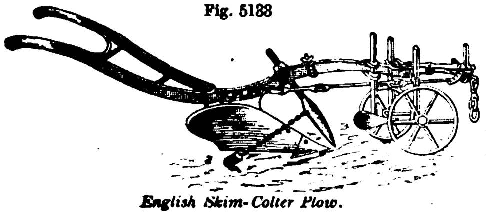
Skil'let. An iron stew or baking pan with a handle.

Skill'ing. A bay of a barn.

Skim-col'ter Plow. A plow having a small share in advance of the main one, the object being to pare and turn into the furrow the surface herbage and manure, so that the main furrow-slice may cover it over entirely.

The illustration shows Howard's improvement (English), with the furrow and land wheel, draft-chain, and *drag-chain*, to pull the weeds into the furrow. Called also a DOUBLE PLOW (which see).

Fig. 5133.

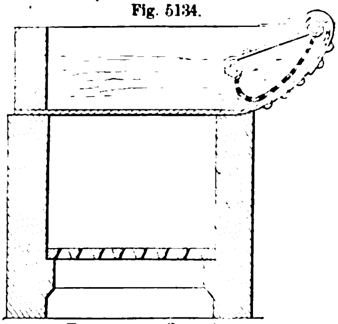


English Skim-Colter Plow.

It was invented about 1775, by Mr. Ducket, a farmer of Surry, England. As contrived by him, it was a "thin plate of iron, with a sharp edge fixed horizontally to a common colter, and its use is to pare off the sward in plowing up grass land or meadow, and to turn it to the bottom of the furrow, where the wrest or mold-board completely buries it with earth; it is likewise useful in plowing rough ground, where mud, stubble, roots, or weeds are on the surface, because it sweeps all floating matter to the bottom of the furrow." — *Monthly Magazine* of December, 1797.

Skim'mer. A perforated ladle or flat dish with a handle for taking the scum from a boiling solution, or from the water in which an object is boiled.

Fig. 5134.



Evaporating-Pan Skimmer.

Cane-juice and that of sorghum, the latter especially, abound in feculencies which rise as a scum as the liquid approaches a boiling temperature, the albumen becoming coagulated and carrying with it to the surface some of the mucilaginous matters. Fig. 5134 shows a provision in a sorghum-evaporator of a skimming-dish hinged to the side and retaining the scum, which tends to collect upon the cooler side of the pan which projects outside of the furnace wall. The scum is discharged by tipping the skimmer.

2. (*Founding.*) A stiff bar of iron, the end of which for a few inches is flattened and curved slightly, like the blade of a saber. It is used at the time of pouring, to keep back the slag or *sullage* which floats on the metal in the ladle. The flat end of the skimmer is coated with loam, and dried to keep the metal from burning to the wrought-iron. Skimmers are usually about 4 feet long, but for crane-ladles they are often 12 to 16 feet.

Skimp'ing-roll'er. A roller of cylindrical brush for removing superfluous paste, etc., as in sizing, calico-printing, and other machines.

Skin. 1. (*Shipbuilding.*) The planking of a ship. The inside, *skin* or *ceiling;* the outside, *skin* or *case.* When of wood, it may be laid on in *carvel, clinker,* or *diagonal* style. When of iron, it consists of iron plates laid in alternate inside and outside strakes.

2. (*Nautical.*) That part of a sail when furled which remains outside and covers the whole. To "furl with a smooth skin" or "skin the sail up smooth" is to turn it well up, and so as to cover the sail neatly.

3. The pelt or hide of an animal, useful as a fur or for making leather. For the latter, see LEATHER; TANNING; TAWING, etc.

The great fur-trade of Leipsic is described by Consul-General Tauchnitz in his report on the Leipsic Easter Fair in 1873. To this fair were brought the produce of Siberia, Russia, Norway, and Sweden, of all Central Europe, of the United States of America, Canada, the Hudson's Bay Territory, Northwest America, Alaska, the Aleutian Isles, and of China. The goods are exported to America, Russia, China, Turkey, to Hungary and the Austrian States, to England, France, and Italy, a considerable quantity also remaining for use in Germany.

The productions of Central Europe were, in round numbers, 120,000 foxes, 200,000 polecats, 50,000 rock-martens, 20,000 pine-martens, 20,000 badger-skins, 6,500 otter-skins, and 125,000 black cats. Foxes fetched from 16 to 22 thalers, according to quality, — on an average, about 18 thalers, — per ten skins. Polecats from 60 to 100 thalers per lot of 40 skins, according to country. Rock-martens reached 6 thalers per skin for German, 7½ thalers for Bosnian and Greek goods; pine-martens, 6 to 7½ thalers per skin. Black cats were sold for 9 to 15 thalers per dozen.

Of Russian and Siberian furs were offered 2,000,000 squirrels of all sorts, 160,000 ermine, 30,000 kolinsky, and 8,000 Siberian sables. Of the productions of North America, about 1,800 sea-

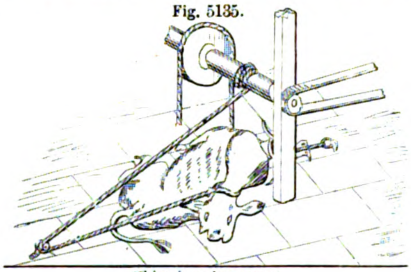
otters were quickly bought up by several Russian merchants. About 80,000 beavers, 40,000 of which were reserved for the demand in England. There were also 3,000 Virginian polecats, 6,000 bear-skins, 220,000 raccoon-skins, 950,000 skunks, 800 silver foxes, 3,500 cross foxes, 45,000 red foxes, 3,000 gray foxes, and 9,000 kitt foxes, 2,500,000 musk-rats, 16,000 sables, and 60,000 small otter-skins.

Of the most important European goods are especially mentioned dyed seal-skins; this fur is in general favor in England and America, and also in Germany and France. Prepared squirrel backs and squirrel bellies, colored Persian and Astrakhan furs, French and Belgian rabbit-skins, Dutch swans and geese, polished rabbit-skin goods and marmot lining, were also exhibited.

Skin'ning-ap'pa-ra'tus. A mechanical appliance for removing the hides from animals.

The hide is ripped as usual, and the head laid bare; the horns being attached to a ring in the floor, a rope is fastened round the neck of the hide, and, running over the pulley on the floor,

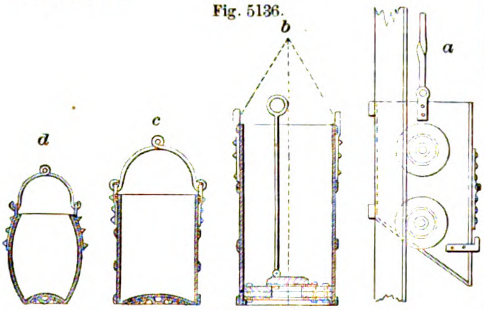
Fig. 5135.



Skinning-Apparatus.

passes round the adjustable drum on the horizontal shaft, which is secured by a clutch. An endless rope on a grooved wheel works the shaft.

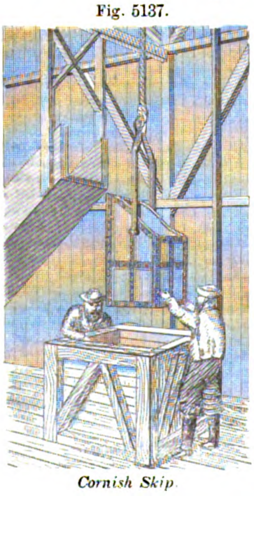
Fig. 5136.



Skips.

Skin-wool. Wool pulled from the dead animal.

Fig. 5137.



Cornish Skip.

Skip. 1. (*Mining.*) A kind of bucket (*a*, Fig. 5136) employed in narrow or inclined shafts where the hoisting-device has to be confined between guides.

It is held to the guides by friction-rollers and flanges, which bear against them, and is provided with a hinged door for discharging material.

b is a water-bucket, used in mines where the quantity to be raised is small, or previous to putting down a pump. On striking the water, the valve *e* rises; it falls by the weight of the superincumbent water when the downward motion is stopped.

c is a *rock-bucket*, frequently used in vertical shafts, and *d* a *kibble*. The latter is adapted for use in shafts that are irregular, or not perfectly vertical. Each has a becket and ring at the bottom, by which it is inverted for dumping.

One ordinary form, used in raising ore to the surface, is a square tube of boiler-iron, having a capacity of about 20 bushels. It has a lip to direct the stuff in discharging.

2. (*Sugar-making.*) A charge of sirup in the pans.

3. (*Fiber.*) A wicker basket mounted on wheels and employed to convey cops, etc., about a factory.

Skip'ping-teache. (*Sugar-making.*) A dipping-pan used in a sugar-boiling house for lifting the concentrated saccharine solution from the open evaporating-pan and conveying it to the cooler.

It is a pan-shaped vessel with a valve in the bottom, worked by a handle. It is lowered by a crane into the pan, the bottom being open; the valve is then closed, the vessel raised, and with its contents removed to the coolers, where the sirup is discharged by moving the handle of the valve.

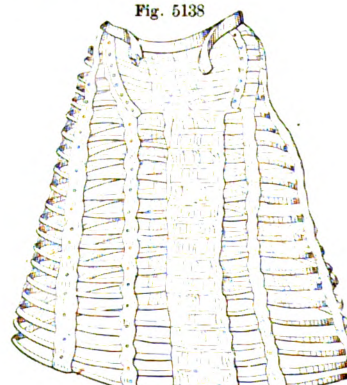
Skip-shaft. (*Mining.*) One boxed off by itself for the skip to ascend and descend in.

Skip-tooth Saw. A saw in which alternate teeth are cut out.

Skip-wheel. (*Carding.*) A wheel in a self-stripping carding-machine to govern the order in which the *top flats* are lifted to be cleaned. In most cases, the action of the *stripper* is upon every other *flat* in order, at the next motion taking the alternate *flats* left on the former passage. In other cases, the action is more frequent upon the flats nearer to the feeding-cylinder, and which become the soonest choked and inoperative, and less frequent upon those nearer to the *doffer*. See CARDING-MACHINE.

Skirt. 1. (*Milling.*) The margin: as the *skirt* or external periphery of a mill-stone; *e. g.* from the *eye* to the *skirt* the *leader-furrows* run.

Fig. 5138



Hoop-Skirt.

2. (*Dress.*) *a.* The hanging portion of a garment below the waist, as of a gown or coat.

b. A petticoat.

Ingenuity is exerted in —

Skirt-clasps.	Skirt-supporters.
Skirt-elevators.	Skirt-springs.
Skirt-metal binding.	Skirt-tapes.
Skirt-protectors.	Skirt-waistbands.

Skirt'ing. 1. (*Building.*) A *wash-board* or *plinth* laid around the wall of a room next to the floor.

2. (*Saddlery.*) A padded lining beneath the flaps of a saddle.

Skirt'ing-board. (*Carpentry.*) A narrow board around the wall next to the floor.

Skit'tle-pot. (*Metallurgy.*) A kind of tall cru-

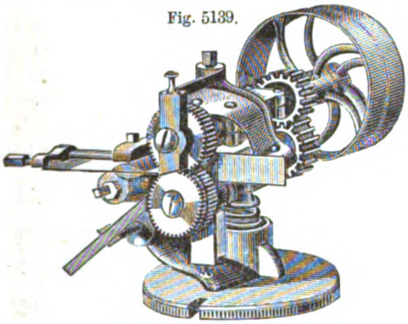
cible swelled toward the middle, used for reducing jeweler's sweepings.

Skive. (*Lapidary Work.*) The revolving table or *lap* charged with diamond-powder, and on which diamonds are polished and other gems are ground.

Ski'ver. (*Leather.*) *a.* A paring tool for leather. *Skiving-knife; skiving-tool.*

b. A machine (Fig. 5139) adjustable to skiver

Fig. 5139.



Tripp's Counter-Skiver.

counters to any desired width of scarf. The knife is held by steel gages at each side of the edge, and is adjusted to any thickness of stock by an automatic feed-roll. A *rand* is produced from any thickness of stock by the same movement. For this purpose, a blade is arranged to strip the stock as the rands are split.

c. A leather prepared from sheepskin with sumac, like imitation morocco, only the skins are split by machinery. The skins are spread out in the ooze and not sewn into bags, as in the morocco process.

Skiv'ing-ma-chine'. (*Leather.*) A machine for splitting skins. See LEATHER-SKIVING MACHINE; LEATHER-SPLITTING MACHINE, page 1281.

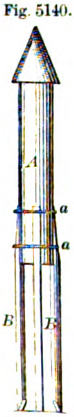
Skute. (*Nautical.*) A kind of large flat-bottomed boat. A scow.

Sky'light. A glazed frame covering an opening in a roof or ship's deck.

A *plane skylight* is about even with, and has the slope of, the roof.
A *raised skylight* is set upon an elevated curb.
A *double skylight* has an outer window for protection, and an inner one, of stained glass, for ornament.

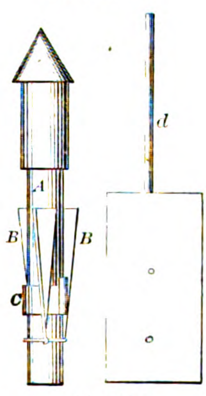
Sky-rock'et. (*Pyrotechny.*) A species of firework — composed of a mixture of niter, sulphur, and charcoal, tightly rammed in a stout paper case —

Fig. 5140.



Sky-rocket.

Fig. 5141.



Sky-rocket.

which is caused to ascend when the compound is ignited at the lower end. It is provided with a stick which is attached to the case at one side.

In Fig. 5140, the case *A* has three short sticks *B B* placed equidistantly around it, and attached by wires *a a*.
In Fig. 5141, the case *A* is provided with wings *B B*, which may be folded down when the rocket is packed for transportation. When erected to serve as guides, they are held by a sliding-collar *C*, which is notched to receive them. A rod *d* passing through a loop in the collar serves to hold them in position for being discharged. The stick is dispensed with. See SIGNAL-ROCKET.

Sky'sail. (*Nautical.*) A square sail set above the *royal.* A triangular sail above the *skysail* is a *sky-scraper* or *flying kite.* If square, it is a *moonsail.* A sail above the moonsail is a *star-gazer.*

Sky-scrap'er. (*Nautical.*) A triangular skysail.

Slab. 1. The outside piece sawn from a log in squaring the side.

2. A thin flat piece of stone or marble for a step, mantel, etc.

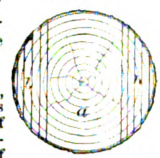
3. (*Fiber.*) A thick web or bat of fiber. See SLUBBING.

Slab'ber. 1. (*Metal-working.*) A quick-motion machine for dressing the sides of nuts or heads of bolts.

2. (*Wood-working.*) A saw for removing a portion from the outside of a log to square it for use as a timber, or that it may be sawn into boards with square edges.

Slab'bing-gang. (*Saw.*) An arrangement of saws in a gate by which a log is cut into a central balk of the required width, and the slab simultaneously ripped into boards of the desired thickness.

Fig. 5142.



The End of a Log ripped by the Slabbing-Gang.

a is the balk which embraces the *heart*, and may be 12, 14, or 16 or more inches wide, according to the desired width of lumber. The other saws are gaged to distance apart, so as to reduce the whole of the slabs into boards by one passage of the log. The *waney* portions of the slab-boards are removed by the EDGER (which see).

Slab'bing-saw. (*Saw.*) A saw specifically used in slabbing logs. In the Ottawa Mills, Chaudiere Falls, these are used in gangs, are of No. 9 gage (Stubs' wire-gage), and 5, 6½, or 7 feet long, according to the size of log.

Slab-board. (*Saw.*) A board cut off the rounding portion of a log; off the *sides* as the log stands on the ways. The log is thereby squared. The boards have sapwood and bark on their edges, which are removed by an edger, making the edges square.

Slab-grind'er. (*Saw-mill.*) A machine used for grinding up the refuse slabs in a water-driven saw-mill, in order to allow them to pass off with the sawdust. This is where refuse stuff is a drug, and the authorities do not allow it to be pitched into the river, as it tends to obstruct navigation, as, for instance, at the Chaudiere Mills, Ottawa, Canada.

Slab-line. (*Nautical.*) A rope fastened to the foot of a sail and used to truss it up after hauling upon the *leech* and *bunt* lines.

Slack. 1. (*Nautical.*) The loose part of a fixed rope.

2. Small coal screened at the mines from household or furnace fire-coal of good quality.

Slack-course. (*Knitting-machine.*) A range of loops or stitches more open than those which precede them.

Slack-wa'ter Nav'i-ga'tion. *Slack-water* or *still-water navigation* has been adopted on several European rivers, but to a greater extent in the United States than elsewhere.

It consists in the erection of dams in the stream, by which the water is dammed back, and its depth is increased. If the fall be moderate, a single dam may produce a stagnation in the run of the water, extending for many miles up the river, and forming a spacious navigable canal. The tow-path is formed along the margin of the river, and is elevated above the reach of flood-water. The dams are passed by means of locks, such as are used in canals. One of the most extensive works on this principle in the country was constructed by the Schuylkill Navigation Company, in the State of Pennsylvania, and consisted in damming up the water of the river Schuylkill. It extends from Philadelphia to Reading, and is situate in the heart of a coal country. It is 108 miles in length, and its construction cost about $2,500,000. This line of navigation is formed by 34 dams thrown across the stream, with 29 locks, which overcome a fall of 610 feet. It is navigated by boats from 50 to 60 tons burden.

Slack-water navigation also occurs at intervals on many of the great lines of canals. About 78 miles of the Rideau Canal, in Canada, are formed in this way, and it is met with on the Erie, Oswego, Pennsylvania, Lycoming, and Lehigh Canals.

The same mode is adopted on the river Severn in England, the dams being made of masonry.

Slade. The *sole* of a plow.

Slag. 1. (*Metallurgy.*) Vitreous mineral matter removed in the reduction of metals. The scoria from a smelting-furnace.

At some furnaces on the Continent of Europe the slag is sold. It is run directly into wagons, or prepared by granulation in water, and is used for making cement and artificial stone, and in the manufacture of alum and crown glass.

At the iron-works of Aulnoye, in Belgium, the slag is cast into slabs for pavements, garden-rollers, and other things. For the former purpose, molds are excavated in the ground around the furnace, and trenches cut to conduct the liquid slag to them. The material is allowed to cool very slowly; its interior is then found to be compact and homogeneous, the exterior consisting of a vitreous crust. The masses are often divided by fissures, but may be cut and dressed into smaller blocks.

Mr. Woodward, of Darlington, England, has patented a method of manufacturing bricks from slag.

The slag from the furnace is run into a series of molds on a revolving table. After removal from the molds, the bricks are annealed in a kiln or furnace, and are ready to be used for any of the purposes to which common brick are applied.

The fracture is said to be close and firm, and they are capable of standing an intense heat. They resist a crushing force of 3 to 4 tons to the inch, and it is claimed can be made at less than half the cost of common brick, though there is considerable loss by breakage.

In another process, invented by Hartmann in Hanover, the slag is granulated by allowing it to flow into a shallow pit, through which a stream of water runs. The material may then be ground fine and used as a building sand. For making bricks, it is mixed, in its coarsely granular state, with half its bulk of water, in a kind of pug-mill. The bricks are molded by machinery, and dried in the open air; in about six weeks they are ready for use. They are said to be stronger than ordinary bricks, and peculiarly adapted for receiving mortar, owing to their rough surface. Their cohesiveness is, however, impaired by the absorption of moisture.

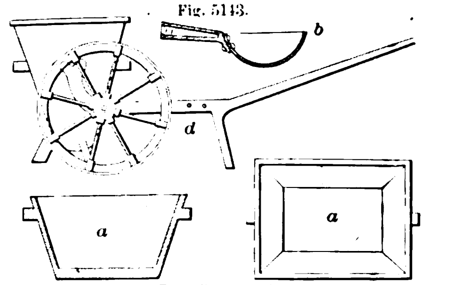
An incombustible non-conducting fibrous material is also prepared by blowing a jet of steam, at a pressure of about 50 pounds, through a thin stream of slag as it falls from a narrow gutter leading from the furnace. By this process it is solidified in the form of delicate fibers resembling asbestus or spun glass. From the appearance of the mass it has received the name of *slag-wool*. It is used as a covering for steam-pipes, boilers, etc. See SLAG-WOOL.

2. (*Founding.*) The fused sullage and dross which accompanies the metal in a furnace, and which it is the business of the skimmer to hold back from the ingate. It is essentially a *very base* silicate of iron. *Cinder; scoriæ; clinker.*

Slag-brick. See SLAG.

Slag-car. A wrought-iron car (*d*) on two wheels, used to contain and carry off the slag of a furnace to a place where it may be dumped.

Fig. 5143.



Slag Pot, Car, and Ladle.

Two pedestals project up in front of the axis of the wheels, so that they may be elevated by depressing the handles and thus lift the slag-pot by its trunnions clear of the ground. *a* shows the slag-pot separately; *b* is the wrought-iron ladle for filling it. A handle, formed of a piece of gas-pipe, is screwed into the socket of the ladle. The slag-pots are of cast-iron, tapering to a flat bottom, as at *a*, or are made conical with three legs to stand on, as in the one on the car.

Slag-fur'nace. (*Metallurgy.*) A furnace for extracting the lead from slags, and from ores containing a small proportion of that metal.

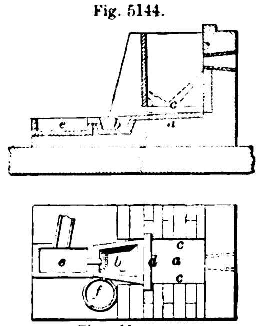
It has a prismatic chamber and an iron sole-plate inclining from the back where the tuyere enters, to the front.

The bottom is covered to the depth of 15 inches with small spongy cinders closely beaten. The rectangular chamber is then filled with turf, which is fired, and alternate layers of coke and slag placed in the furnace. The reduced metal filters through the lower layer of cinders, and is received in a pot also filled with cinders. The slag, being too viscid to penetrate these, flows off above.

Slag-hearth. (*Metallurgy.*) A furnace for treating slags run from the surface of lead in a smelting-furnace.

The shaft is a parallelopipedon 26 × 22 inches at the base, and 3 feet high. The sole-plate *a* is of cast-iron, and slopes down to the receiving-basin or fore-hearth *b*; cast-iron beams, called bearers, *c c*, on each side of the sole-plate, support the side walls of sandstone, and also the cast-iron plate *d*, called the *fore-stone*, forming the front of the shaft. The back is of cast-iron up to the tuyere-hole, above which it is of sandstone. In front of the fore-hearth *b* is a cistern *e*, through which water flows, so that slags which flow over the fore-hearth may be shattered, and the lead contained in them be readily washed out.

Fig. 5144.



Slag-Hearth.

The lead itself flows over the fore-hearth into an iron pot *f*, which is kept hot over a fire.

The metal obtained in this way is less pure than that extracted directly from the ore.

Slag-wool. A non-combustible and non-conducting material made from the slag of a cupola-furnace, by directing upon the slag in its fluid state, as it runs from the furnace, a strong jet of steam. By this the slag is thrown, in a condition of fine fibers, into a cast-iron chamber or receptacle prepared and placed for the purpose, from which it is gathered in a form resembling wool. It was shown at the Vienna Exhibition by an establishment at Osnabrueck.

Slaie. (*Weaving.*) A *reed*. See SLEY.

Slake-trough. (*Blacksmithing.*) The water-trough in which a blacksmith *slakes* or cools his tools or his forging.

Sla'kin. (*Metallurgy.*) A spongy, semi-vitrified substance mixed by smelters with the ores of metal to prevent their fusion. It is the scoria or scum separated from the surface of a former fusion of the same metal.

Slam. The refuse of alum-works, used as a manure.

Slap'ping. (*Pottery.*) The process of working clay by dividing a block and slapping the halves together. This develops the plasticity, makes the mass homogeneous, and expels air-bubbles. The *grain* of the mass is preserved, the pieces being dashed parallel upon each other. The process is repeated again, the dividing instrument being a wire. See SLOPING; WEDGING; SLICING-MACHINE.

Slash'er. A sizing-machine for warp-yarns. The yarns are received from a number of rollers on the right, but two of which are shown in the engraving. They are then sized, brushed, and dried, the latter by passing over and under large heated cylinders. The name *slasher* originated as a playful term to indicate the much greater rapidity of the machine as compared with the ordinary *warp-dresser*.

The extra amount of work is done by having a much greater drying surface for the yarn to pass over after being sized. In the slasher, also, the yarn runs through boiling size; in the dresser it is cold or only moderately warm.

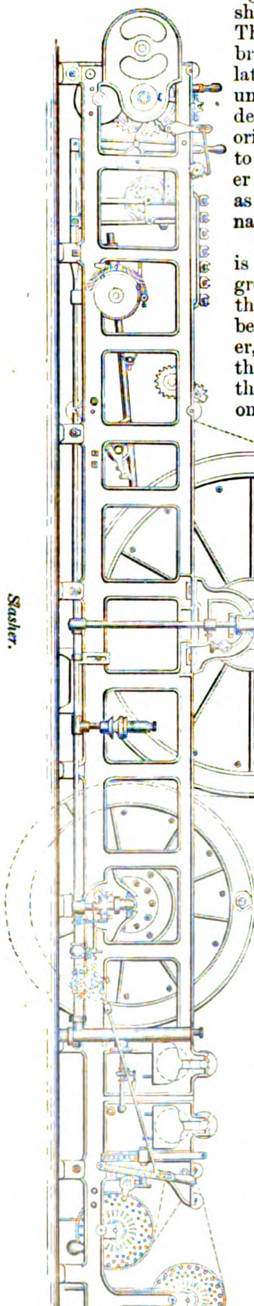


Fig. 5145.

Slasher.

The name is perpetuated in other succeeding machines and appliances, as *slasher-warpers, slasher-combs, slasher-cloth*, etc. See also official catalogue of the English Exhibition for 1862, Class VII. pages 6, 7.

Slat. A thin strip or flat bar.

1. In a bedstead, the *slats* are transverse pieces, resting at their ends upon the *side-rails*.

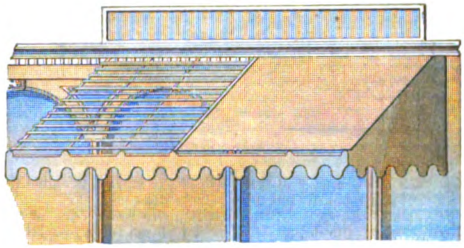
2. (*Vehicle.*) *a.* A bent strip which bows over the seat and forms one of the ribs of the canopy. A *bow*.

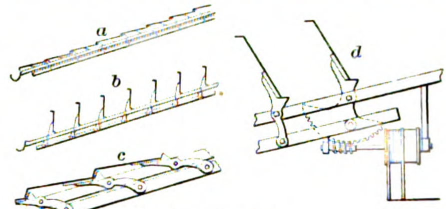
b. The *sloats* or rounds of a kind of cart or wagon bed.

3. The foundation of a basket, consisting of crossing sets of parallel rods interlaced and forming a nucleus for the commencement of the spiral courses of which the bottom is made.

Slat-awn'ing. Fig. 5146 shows a corrugated iron slat-awning. The slats are pivoted and are raised and lowered, those of each set being connected by bars by means of segment-racks engaging with worms upon the shafts of drums which are turned by

Fig. 5146.





Slat-Awning.

cords leading to the footway beneath. When closed, as at *a*, their down-turned edges overlap. *b* shows the slats raised; *c d* illustrate the mechanism for raising and lowering them.

Slate. A metamorphic clay rock, frequently fossiliferous. It is readily divisible into thin plates, and, being easily worked and smoothed, is much employed for roofing and in the manufacture of mantels, billiard-tables, and other similar objects. In the quarry, the direction of these cleavage planes is usually vertical or nearly so, but never coincident with those of the beds and joints. The masses are, therefore, removed by cutting trenches in the side of the hill and splitting the rock in vertical layers. As the perpendicular breast becomes too high for convenient working, say 40 feet, a second trench is cut above the first; then a third, and so on.

In the great slate quarries of Ybron, six miles southeast of Bangor in N. Wales, sixteen of these stages are in progress together, the lower ones being gradually widened by the getting of the slates as the upper ones are advanced. In the upper part of the quarry the slates are removed with crow-bars; but the slates become harder as they are lower from the surface, and require the use of gunpowder to detach the main masses. The miners engaged in drilling the holes for the powder are suspended by ropes from the upper parts of the rock, and are liable to many and severe accidents. After the slates are detached by powder or otherwise, they consume considerable labor in splitting them with wedges and mallets into marketable sizes, and reducing them to the several grades required for roofing and other purposes.

Slate adapted for ordinary economic uses is not very common. A number of varieties are, however, found in Cornwall, Wales, Scotland, and Ireland, and also on the Continent of Europe.

Those from the Ardennes, from Angers on the Loire, and from Nassau, are largely exported.

In this country, Vermont furnishes slates of unsurpassed quality and beauty. Their quarrying and manufacture are beginning to constitute an important feature of national industry, promising large increase in the future.

Aluminous slate yields alum.

Adhesive slate is porous and adheres readily to the tongue.

Bituminous slate yields coal-oil.

Whet slate has a fine grain and makes hones.

A tough kind, *hornblende* slate, is used for flagging and sidewalks.

A soft kind, containing carbon, — *drawing* slate or *graphic* slate, — is used for pencils.

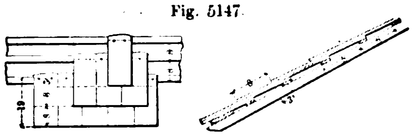
Polishing slate has a peculiarly fine grain, and is found in Bohemia. It is used in slips and in powder.

Slate clay consists of alumina and silica, and, from the absence of fluxes, makes a refractory fire-brick.

2. A thin riven slab of slate used in roofing.

The upper surface of a slate is called its *back*, the under surface the *bed*, the lower edge the *tail*, the upper edge the *head*. The part of each course of slates exposed to view is called the

Fig. 5147.



"*Countess*" *Slating.*

margin of the course, and the width of the margin is called the *gage*. The portion hidden from view is the *cover*.

The *bond* or *lap* is the distance which the lower edge of any course overlaps the slates of the second course below, measuring from the nail-hole, and may be from 2 to 4 inches.

In preparing slates for use, the sides and bottom edges are trimmed and the nail-holes punched as near the head as can be done without risk of breaking the slate, and at a uniform distance from the tail, regard being had to the spring of the laths. Slates are laid on *laths*, *battens*, or sheathing, and must break joint. The nails are of copper, zinc, or tinned iron. In England, 1,200 slates constitute a thousand, common sizes, as follows: —

Description.	Size. Length. Ft.	Size. Length. In.	Size. Breadth. Ft.	Size. Breadth. In.	Average Gage in Inches.	No. of Squares 1,200 will cover.	Weight per 1,200 in Tons.	No. required to cover one Square.	No. of Nails required to one Square.
Doubles	1	1	0	6	5½	2	¾	480	480
Ladies	1	4	0	8	7	4½	1¼	280	280
Countesses	1	8	0	10	9	7	2	176	352
Duchesses	2	0	1	0	10½	10	3	127	254
Imperials	2	6	2	0	A ton will cover 2¼ to 2½ squares.				
Rags and Queens	3	0	2	0					

Other denominations and sizes are —

	Ins.		Ins.
Small	11 × 7	Viscountess	18 × 10
Plantations	12 × 10 13 × 10 14 × 12	Marchioness	22 × 12

A *square* of slate or slating is 100 superficial feet.

The *pitch* of a slate roof should not be less than 1 in hight to 4 of length.

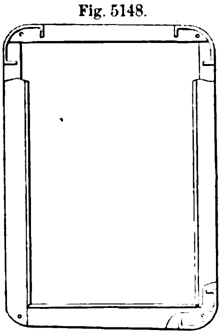
Dimensions of Slates (American).

Ins.	Ins.	Ins.	Ins.	Ins.	Ins.
14 × 7	16 × 8	18 × 10	20 × 11	22 × 12	24 × 13
14 × 8	16 × 9	18 × 11	20 × 12	22 × 13	24 × 14
14 × 9	16 × 10	18 × 12	22 × 11	24 × 12	24 × 16
14 × 10	18 × 9	20 × 10			

The thickness of slates ranges from 3/16 to 5/16 of an inch, and their weight varies from 2.6 to 4.53 pounds per square foot.

3. A tablet for writing upon, formed of slate, or of an imitation of slate.

Fig. 5148.



Slate.

School-slates are made from a fine and soft quality of slate. The great demand for them has led to various improvements in the manner of making and uniting the frames, and to the invention of special machines for this purpose. Slate-frames are now generally made with rounded angles, and one invention consists in securing the parts together more firmly by wires entering grooves at the corners, and having bent ends, which are inserted into holes in the side and end pieces.

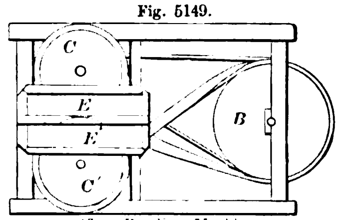
Artificial slates are prepared by coating the surface of wood or paper with a fine gritty substance, as pulverized emery or pumice, mixed with black size or paint; or the surface is painted black, and dusted with the powder before it becomes dry.

Slate-axe. A slater's tool. It has a blade for trimming the edges and a spike for making nail-holes in the slate. A *sax* or *zax*.

Slate-bev'el-ing Ma-chine'. A machine for beveling the edges of school or other slates.

The slate is held in the opening between the two adjustable guides *E E'*, its edge being presented to the two bevel-edged

Fig. 5149.



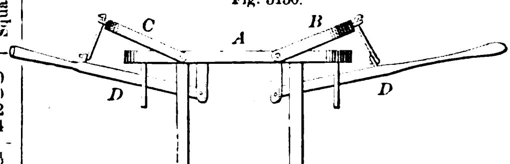
Slate-Beveling Machine.

wheels *C C'*, which are rotated in opposite directions, so that their acting surfaces move in the same direction, by a crossed belt passing around the pulley *B*.

Slate-cut'ter. A machine for cutting the edges of roofing or other slates, to give them a rectangular or other regular form.

In Fig. 5150, the slate is laid on the table *A*, and its ends

Fig. 5150.

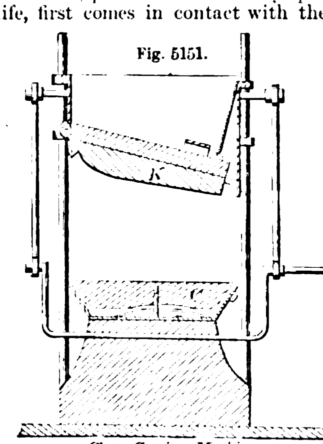


Slate-Cutter.

trimmed by hinged knives *B C* of curved or other suitable shape, depressed by the levers *D D*.

Slate-cut'ting Ma-chine'. A cushion *K* within the box-knife, pressed downward by springs below the knife, first comes in contact with the slate on

Fig. 5151.

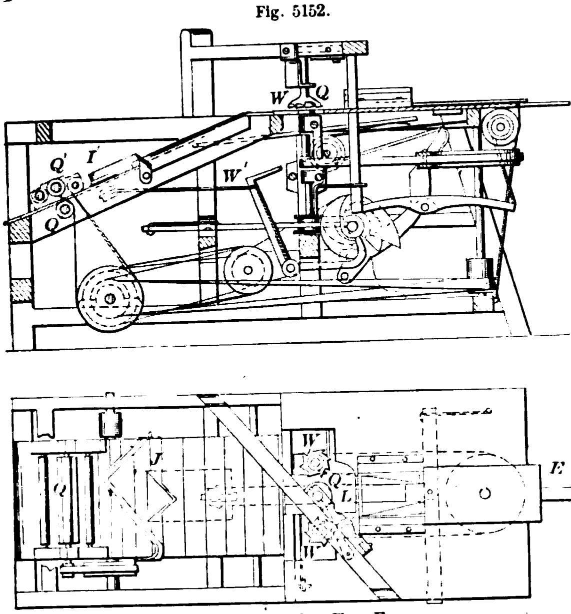


Slate-Cutting Machine.

the cushioned bed *C*, and rises as the knife descends, allowing the slate to be adjusted between the beds so as not to be broken.

Slate-frame. In the machine for dressing slate-frames (Fig. 5152), the frames are arranged in a pile, and are fed forward one by one by the action of the pusher *E* on to the revolving table *L*, where the corners are rounded off and edges dressed by the rotary knives *W W*. It is then advanced by the pusher *J'*, which, with the angular stop *I'*, presents it corner-

Fig. 5152.



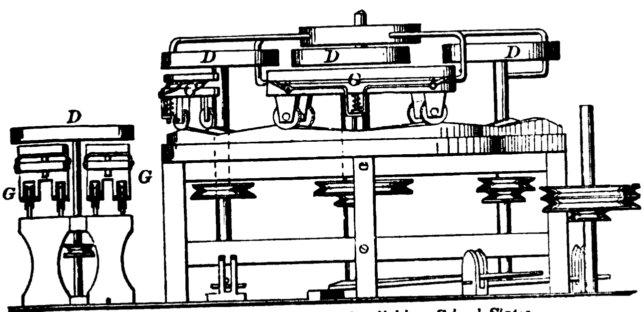
Machine for dressing Slate-Frames.

wise to the cutters Q Q', by which the sides are planed.

Slate-mak'ing Ma-chine'. Fig. 5153 is a machine for grinding and polishing school-slates. The slates are supported on cars G, which are connected by arms with a vertical shaft, by which they are caused to move slowly around in a circular track, having a series of inclines. The distance apart of the corresponding parts of each similar incline is exactly equal to that between the front and hind wheels of the car, which is thus caused to remain perfectly level as it rises to present the slate to the grindstones D, and falls during its forward movement.

Slate-peg. A kind of nail used in securing slates on a roof. A slater's nail.

Fig. 5153.



Machine for grinding and polishing School-Slates.

Slate-pen'cil. The common irregularly shaped black slate-pencils, once the only kind known, are made in Germany. These have been pretty much superseded in this country by the softer, neater, and greatly superior article, known as soapstone pencils, made from a peculiar stone found near Castleton, Vt. This stone contains over 50 per cent of silica, a large proportion of alumina, and also some potash and iron; and, while having some resemblance to soapstone, more nearly resembles slate in texture and capability of being split readily into plates.

In the manufacture of pencils, it is first split into slabs 1 to 2 inches thick, which are then sawn into blocks 6 to 7 inches long and 4 or 5 inches wide. With a thin blade of steel and a hammer these are split into plates about one third of an inch thick, which are next passed between two flat-edged knives to plane them. The plate is then fed to a machine in which it is passed successively beneath a series of grooved cutters, each of which cuts a row of deeper incisions into the slab, until, on emerging from the machine, its upper side is covered with convex flutings, the channels between which penetrate half through the stone. It is then transferred to a second machine, where its other side is subjected to the action of a series of similar cutters, by which the pencils are completely rounded and separated from each other. They are next sawed to uniform lengths, the sizes varying from $3\frac{1}{2}$ to 6 inches; and, finally, pointed on a grindstone. In some cases they are afterward painted.

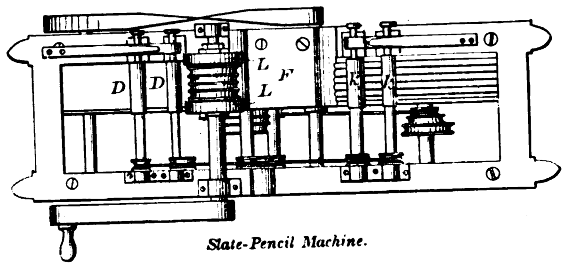
The dust and waste, which is said to amount to 90 per cent of the original material, is utilized by grinding to an impalpable powder, which is used for mixing with paper-pulp to give it body and enable it to receive a *satin* surface.

As the stone contains over 30 per cent of alumina, the refuse is also available for the manufacture of alum.

Slate-pen'cil Ma-chine'. A machine for forming pencils at one continuous operation.

The slate is fed by the rollers D D to the grooved rotary cutter L L, which shapes their upper sides; other rollers convey them beneath the plate F, which is grooved to correspond with the upper halves of the pencils, and their lower sides are shaped by a similar rotary cutter beneath the plate. They then pass beneath the rollers k k, which convey them away.

Fig. 5154



Slate-Pencil Machine.

Slate-saw. A machine for trimming the edges of slate-slabs to shape. In the example, the slab is laid on a traversing bed and passes beneath two circular saws which are gaged such a distance apart as the proportions of the slab may warrant or the width of the piece required may justify. The blades are made of diameters from 2 feet up to 13 feet, and the machine is used for other varieties of stone beside slate.

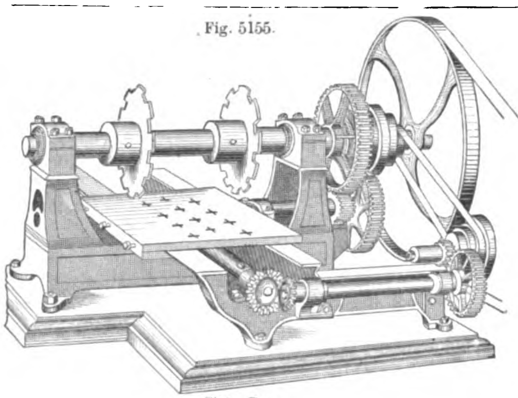
Slate-trim'ming Ma-chine'. See SLATE-CUTTER.

Slate-wip'er. A sponge-holder for wetting and wiping school-slates. It has a sponge on the end moistened by water oozing from the interior.

Slat'ing. The slate covering of a roof, taken as a whole. See SLATE.

Slat-ir'on. (*Vehicle.*) The iron shoe or ter-

Fig. 5155.

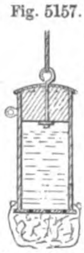


Slate-Saw.

mination of the *bow* or *slat* of a carriage-top. The shoe is hinged to the stem by a pivot-pin and has an envelope of leather. In the example, the ends of the bows are fitted into ferrules, having semi-circular extensions upward and longitudinal screw-threaded holes for the reception of screws in the end pieces.

Fig. 5156. Fig. 5157.

Slat-Iron.



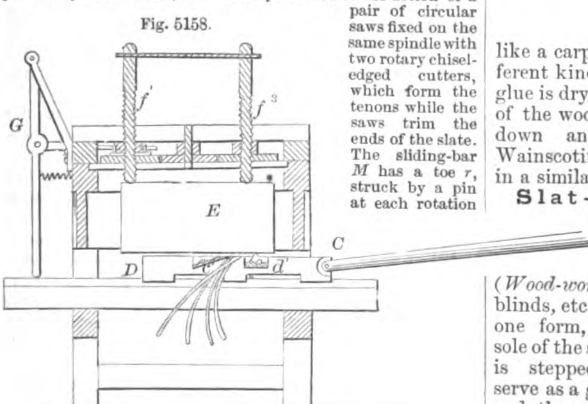
Slate-Wiper.

Slat-ma-chine′. A machine for tenoning and automatically inserting the staples in Venetian-blind slats.

The machine (Fig. 5158) has a carriage *D C* reciprocated by a pitman. A series of vertical cutters *d′* on the carriage make longitudinal incisions in front of the broad inclined cutter *c*, which follows and severs the whole row of slats simultaneously from the block. The block *E* is pressed down to the cutters by screws f^1 f^3, advanced downwardly by gear-wheels operated by a pawl movement from the lever *G*, which is vibrated at each reciprocation of the carriage. The several splints pass downwardly through a throat in the carriage-stock.

In Fig. 5159, the slat is held between the revolving heads *I I* on the extremities of the arms *H H′* attached to the shaft *G*, and raised or depressed by the lever *J′*, so as to be presented to the action of a pair of circular saws fixed on the same spindle with two rotary chisel-edged cutters, which form the tenons while the saws trim the ends of the slats. The sliding-bar *M* has a toe *r*, struck by a pin at each rotation of the wheel *Q*, causing a forward movement of the bar, which drives a staple, escaping from the receptacle *P* into the side of the slat.

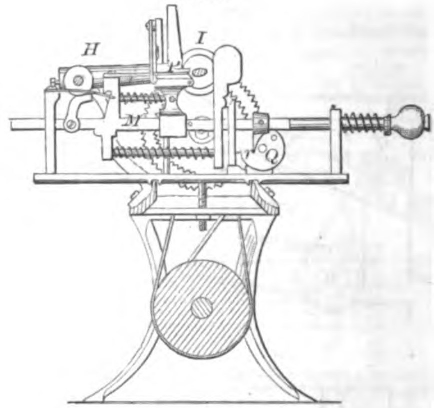
Fig. 5158.

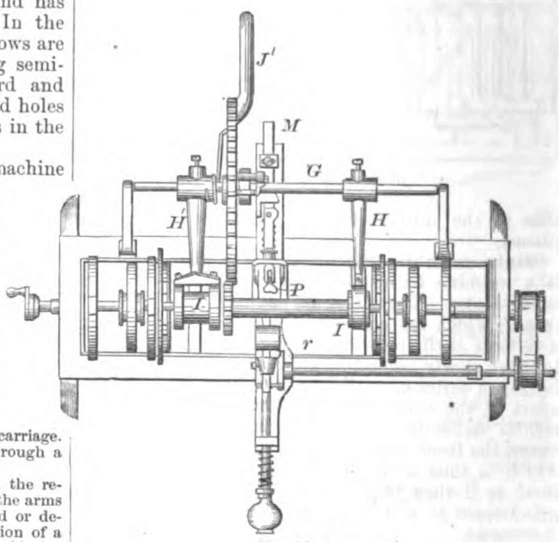


Machine for cutting Slats for Blinds.

Slat-mat′ting. A floor covering of wooden slats or veneers on a flexible fabric, which may be rolled like a carpet. In the example, narrow strips of different kinds of wood are glued upon cloth. After the glue is dry, the surface of the wood is planed down and finished. Wainscoting is made in a similar manner.

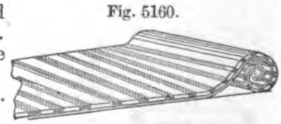
Fig. 5159.





Slat-Machine.

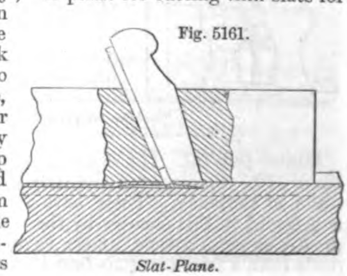
Fig. 5160.



Slat-Matting.

Slat-plane. (*Wood-working.*) A plane for cutting thin slats for blinds, etc. In one form, the sole of the stock is stepped to serve as a gage, and the cutter has a forwardly projecting lip which cuts and lifts the bottom of the slat while a vertical cutting-edge severs

Fig. 5161.



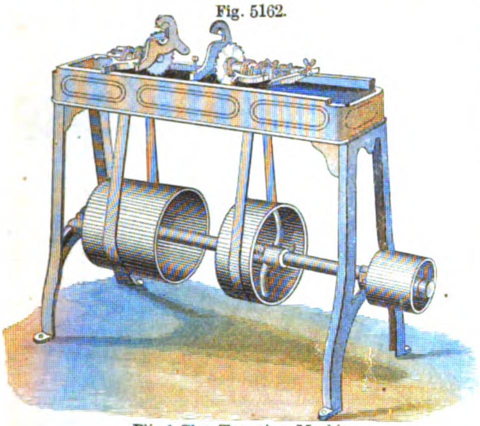
Slat-Plane.

it at the side. The splint passes to the rear through an opening in the cutter. Several cutters may be arranged in the stock so as to cut several slats at once.

Slatt. (*Masonry.*) A thin slab of stone used to cover rougher or less expensive masonry or brick-work (not *slate*).

Slat-ten′on-ing Ma-chine′. A machine for cutting circular tenons on the ends of blind-slats.

Fig. 5162.

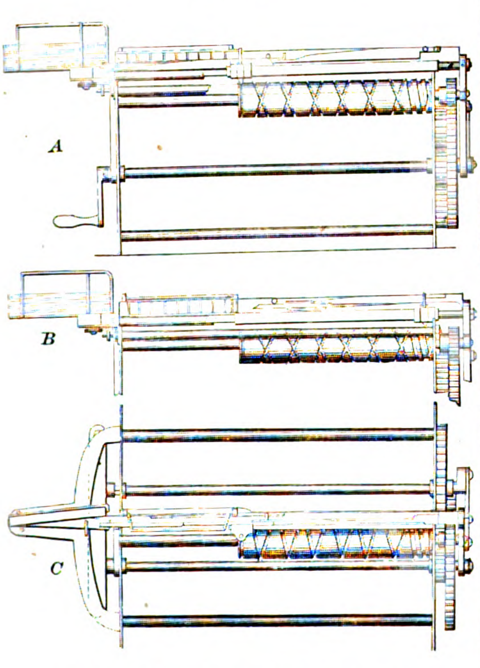


Blind-Slat Tenoning-Machine.

The slat is placed within two revolving disks, by turning which it is brought in contact with two sets of circular saws. These cut the shoulder and round the tenon at one operation.

Slat-weav′ing Loom. A loom for making woven goods, in which the warp consists of slats, palm-leaf, whalebone, straw, or other material, which

Fig. 5163.



Baldwin's Loom for weaving Palm-Leaf, etc.

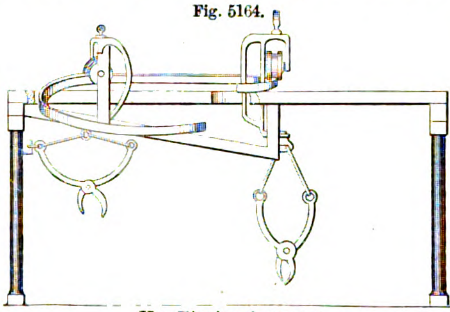
is cut in lengths equal to the width of the goods, and laid into the shed piece by piece, instead, as in other looms, of being fed off continuously from a bobbin or spool.

Fig. 5163 represents a machine of this kind; *A* being a front view, *B* a sectional view of the upper part detached, *C* a top view. The slats are arranged in a pile in such position on the side of the loom, that a pin on a sliding frame operated by the lay pushes out the inner end of the under slat, so that it can be seized by the reciprocating nippers and drawn into the shed. The slat, when in place to be beaten up, is held by a pressure-bar hinged on the lay.

Patent No. 135,427 has devices to support the strips of wood while being introduced into the shed, to prevent their coming in contact with the threads of the warp. The strips composing the woof are fed into a slotted lay by a pair of feed-rolls, the lay having a cap which serves as a guide to keep the slat in place while it is being fed into the lay, and is raised to release the strip from its slot when the lay is beating forward. See also PALM-LEAF LOOM, page 1600, and list of patents under STRAW-FABRIC LOOM.

Slaugh′ter-ing-ap′pa-ra′tus. Machinery for slinging slaughtered animals, to assist in skinning, gutting, cleaning, as the case may be. For beeves,

Fig. 5164.



Hog-Slinging Apparatus.

it usually consists of a mode of hauling the animal up to the place where it is stunned by a pole-axe and then bled; also of a hoisting tackle by which it is lifted while the skin and viscera are removed, and then swung clear of the floor to be washed and left to cool.

Hog-slaughtering apparatus consists of scalding-tubs and slinging devices, the latter shown in the cut. The swiveled clutch is supported upon a grooved roller which travels on a helical track to gradually elevate the load. The hog from the scalding-tub is slung by its gambrels from the clutch and passed in succession to the gutters and the cleaners; it is then passed on and transferred to the hooks where the hogs hang over night to cool.

Slay. (*Weaving.*) A weaver's reed. A *sley.*

Sleave. The knotted and entangled part of silk or thread.

Sled. A vehicle on runners, used for hauling loads. It corresponds to the wagon as the sleigh does to the carriage among wheeled vehicles, the two latter being intended for passengers.

The sleds of the Esquimaux vary in their materials and shape. According to Captain Lyon, the best are made of the jawbones of the whale sawn to about two inches of thickness and from six inches to a foot in depth. These are the runners, and are shod with a thin strip of the same material. The sides are connected by pieces of bone, horn, or wood, firmly lashed together. In Boothia, Captain Ross saw sleds in which the runners were made of salmon, packed into a cylinder, rolled up in skins, and frozen together. In spring the skins are made into bags and the fish eaten.

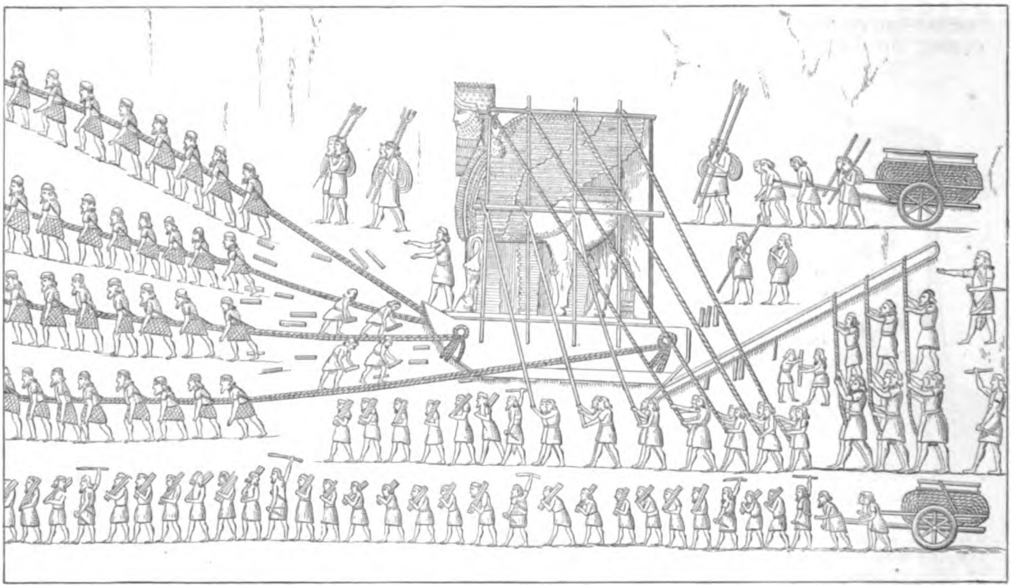
Fig. 5165, from a bas-relief at Koyunjik, illustrates the mode

adopted by the ancient Assyrians for removing colossal figures from the quarry, where they were hewn, to the place which they were intended to occupy.

The figure was mounted on a sled and protected by a framework of spars or beams, crossing each other at right angles, and tightened by means of wedges. To prevent the colossus from upsetting, ropes attached to the top of the framework were held by men at each side. Wooden forks or props, held by men, were also applied to the second cross-pieces to steady it.

Rollers were placed beneath the upwardly curved front of the sled as it advanced, and were collected by men at the rear. It was drawn by four gangs of men by means of four large ropes attached to projecting pins, two at the front and two at the rear of the sled, and secured by a knot which could not slip.

Fig. 5165.



Assyrians removing a Human-Headed Bull (from a Bas-Relief at Koyunjik).

To impart the first impulse to the mass and to start it again after stopping, a long lever, with wooden wedges beneath to form a fulcrum, was applied at the rear end of the sled, and was worked by ropes extending from near the extremity of its long arm to the ground and drawn upon by men.

A man standing on the front of the sled controlled the movements of the laborers engaged in pulling; others, supervised by foremen, carried the spare rollers and forks, and drew cars containing extra hauling ropes, while a superintendent at the rear directed the whole operation.

The sled was also employed by the Egyptians in transporting large masses of stone, as is illustrated in their sculptures. In a grotto behind E'Dayr, a village between Antinoë and El Bersheh, is the representation of a colossus on a sled drawn by 172 men in four rows of 43 each; a man standing on the pedestal at the front of the sledge pours a liquid, probably grease, from a vase, for the purpose of lubricating the planks or ways, though these are not shown, over which it slid. A superintendent, standing on the knee of the statue, appears as if clapping his hands as a signal for a simultaneous pull; or is, perhaps, preparing to catch something which a person on the ground appears to be about to throw. Men carrying vases containing grease, or perhaps water, and others with implements of some kind follow, while supervisors or taskmasters bring up the rear. Relays of drawers walk behind the sledge. The ropes are all attached to the front of the sled. The number of men employed may have been much larger than that actually shown. This sculpture is of the age of Osirtasen II., the contemporary of Joseph, between 1651–1636 B. C. See Wilkinson's "Ancient Egyptians," First Series, Vol. III. p. 328.

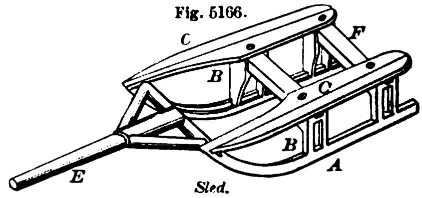
Country sleds are made in various ways The *Yankee* sled has wide runners which elevate the benches sufficiently. The *knee*-sled has knee-pieces which rest on the runners and support the benches. *Bob*-sleds are short. *Log*-sleds are short and have a heavy hind bench to support the log.

Fig. 5166 is a view of a sled, showing the runners *A*, knees *B*, fenders *C*, benches *F*, roller, hounds, and tongue *E*.

Fig. 5167 is a pair of bob-sleds (*bob*, short), used instead of a single long sled of equal length, on account of the facility of turning and greater handiness in other respects.

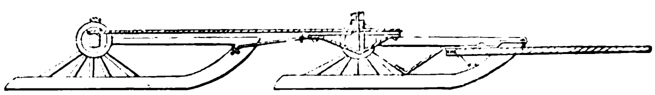
Fig. 5168 is a reversible dumping-sled. On arriving at the place to dump a load, the sled is upset and is ready for reloading. The sled projects above and below the floor, and the runners are rounded at each end. It is drawn by a chain looped on to a hook, which is disengaged to bring the dumping-chain into action.

Fig. 5166.



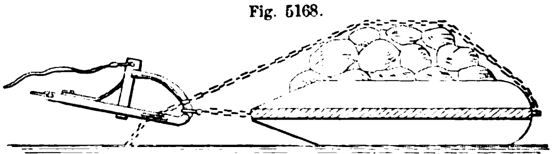
Sled.

Fig. 5167.



Bob-Sleds.

Fig. 5168.



Reversible Dumping-Sled.

Sleds for children and youth are made in many forms. Two may be cited.

Fig. 5169 has a pair of rudders behind the runners for guiders, the two being simultaneously acted on by cords connected to a tiller-lever.

Fig. 5169

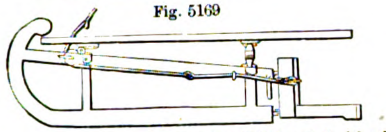


Fig. 5170 is a sled with a brake.

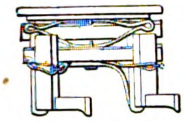
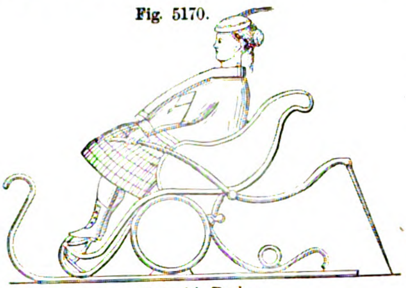


Sled with Rudders.

Sled-brake. (*Vehicle.*) A device to prevent too rapid motion of a sled. It is usually a prong brought into contact with the ice.

Fig. 5171 shows one in which the brake is operated by the driver, who turns a lever projecting upwardly from the front end gate of the wagon-bed and thereby depresses the scraper.

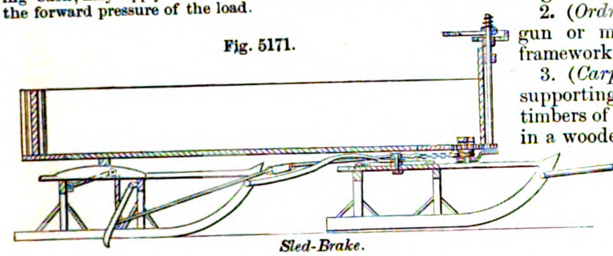
Fig. 5170.



Sled with Brake.

In Fig. 5172, the brake is so arranged that the team, in holding back, may apply the brake with a force proportioned to the forward pressure of the load.

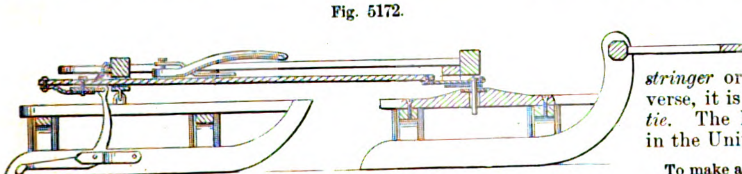
Fig. 5171.



Sled-Brake.

In Fig. 5173, depressing the lever *a* causes the parts *b*, to which the pivoted brakes *c* are hooked, to assume a vertical

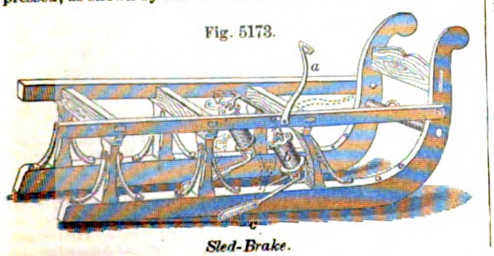
Fig. 5172.



Automatic Sled-Brake.

position, the points of the brakes being at the same time depressed, as shown by the dotted lines.

Fig. 5173.



Sled-Brake.

Sledge. 1. (*Vehicle.*) A vehicle on runners is called a *sledge* in England, where such things are but little used. The true word, *sled*, is used in America, and is derived from the Anglo-Saxon word *slidan*, to slide. See SLED.

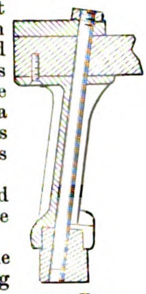
2. The heavy hammer of a smith, wielded by both hands. A *sledge-hammer.*

The *up-hand* sledge is used for comparatively light work, and seldom lifted above the head.

The *about* sledge is grasped by both hands at the end of the handle and swung at arm's length over the head, giving the heaviest possible blow.

Sled-knee. (*Vehicle.*) One of those portions of the frame of a sled or sleigh which rest on the runners and raise the fenders and benches a sufficient hight above the ground. (See SLED.) In the example, a rod passes through and is made fast to the sleigh-runner, its upper end protruding through the bottom board and provided with a nut for tightening. A shield protects the rod, and forms suitable bearings for the runner and cross-piece.

Fig. 5174.



Sled-Knee.

Sled-run′ner. One of the curved pieces on which a sled slides. (See SLED.) Sleigh-runner.

Slee. (*Shipwrighting.*) A cradle placed beneath a ship when hauling her up for repairs.

Sleep′er. 1. (*Shipbuilding.*) *a.* A fore-and-aft floor-timber in a ship's bottom.

b. A knee-piece connecting the transom and after-timbers to strengthen the counter. Similar timbers strengthen the bows of whalers.

2. (*Ordnance.*) The undermost timbers of a gun or mortar platform, or, generally, of any framework.

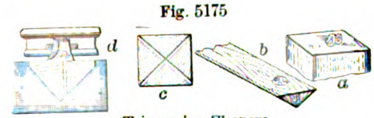
3. (*Carpentry.*) *a.* One of the set of timbers supporting the lower floor of the building. The timbers of the upper floors are *joists.* The sleepers, in a wooden frame, rest on the sills. In a brick or stone house they rest in the walls. This distinction is not always maintained, and they are indifferently called *joists.*

b. One of a set of logs or scantling laid beneath a rough floor, as of a pen, shed, or temporary stable.

4. (*Railway Engineering.*) One of the timbers supporting a railway-track. When it is longitudinal with the track, it is called a *stringer* or *sill*; when it is transverse, it is called a *cross-sleeper* or *tie.* The latter is the usual term in the United States.

To make a super-excellent job, some of the best English railways first used hewn blocks of stone for sleepers (*a*, Fig. 5175). Brunel adopted them on the Great Western Railway, England. It was found that they were too solid and unyielding, and wood is now preferred. It is sometimes *kyanized*, or treated by

Fig. 5175



Triangular Sleepers.

equivalent processes, to render it less liable to decay. See WOOD, PRESERVATION OF. The blocks contained about four cubic feet. Triangular cross-ties *b c d* are *got out* of square balks by ripping diagonally, and are made to rest in longitudinal sills.

This mode looks well on paper, but is costly and subject to decay.

The usual mode is to set cross sleepers beneath the rails, imbedded in a ballast of broken stone. To these *ties* the rails are secured by chairs or spikes; sometimes by chairs at the joints and spikes at intervening points.

The ordinary English sleeper is 9 feet long, 10 inches wide, and 5 inches thick; the distance apart is from $2\frac{1}{2}$ to 3 feet.

On some of the English railways, triangular sleepers are laid in ballast, the angle beneath.

Mr. Holley, in his report on railways, gives the dimensions and intervals of sleepers on nine New York railroads as —

Average number of sleepers per mile.........	2,242
Length in feet (4 feet $8\frac{1}{2}$ inches gage).........	8.07
Width of bearing surface in inches...........	7.02

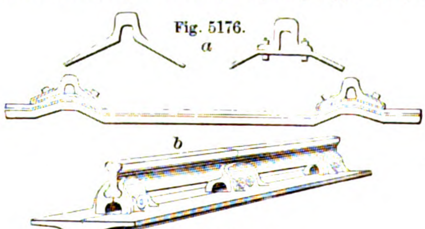
Wooden blocks have been substituted for cross sleepers, and with some success. The object has been to prevent the rocking motion induced by the bearing of the middle of the sleeper on the tightly packed ballast when the support below the rail had been pressed out. The same object was attained in France by cutting the sleepers across at midlength, leaving every twelfth sleeper uncut, to act as a *tie*.

The *sandwich system* of W. B. Adams (England) is a longitudinal support by a timber on each side of the rail, and gripping it beneath the head. The *web* of the rail, which is clasped by the side timbers, is made $\frac{1}{4}$ to $\frac{3}{8}$ inch in thickness, the rail weighing 70 pounds per yard, and being 8 inches deep. It has no appreciable vertical flexure under the passing train, and the longitudinal sleepers are made available for several sets of rails. The rail, being supported by a sleeper beneath the head, does not depend upon the stiffness of the web, which is relieved of lateral strain, being *sandwiched* between the sleepers. The sleepers are secured by bolts and nuts, which pass through holes in the webs of the rails. The rail is double-headed.

By Dimpfel's longitudinal system, the rail is supported beneath its head and foot by continuous longitudinal sleepers.

Seaton's system is also longitudinal, and to insure the perfection he aimed at, requires a heavy rail, being supported by foot

Fig. 5176.



Barlow's Sleepers.

flanges on sleepers with 17 inches breadth of bearing. It is stated that rails of 90 pounds, laid on his system on the London and Northwestern Railway, after the passage of 100 trains daily for two years, showed no signs of abrasion at the joints or elsewhere. See Railway-rail.

Barlow's iron railway-sleeper (English) (*a*, Fig. 5176) is adapted for a saddle-shaped rail, and rests upon iron *ties* or *sleepers*, which have seats for the rails, which are bolted thereto. Like some of the other iron devices, it was intended to preserve the permanent way against the attacks of insects in hot climates.

Fig. 5177.

English Chairs and Sleepers.

Barlow's longitudinal cast-iron sleeper (*b*) has a central line of division and junction; to each cheek the halves of chairs are cast, and these embrace the rail when the halves of the sleepers are bolted together.

Brunton's combined cast-iron chair and sleeper (*c*, Fig. 5177) consists of a base-plate whose flanges prevent horizontal displacement, and whose broad surface rests upon the ballasting of the way. The chair is cast with the sleeper. The sleepers of the respective rails are tied together by bolt-rods.

Greave's chair and sleeper (*d*) consists of a hollow cast-iron frustum, whose upper surface supports the chair. The sleepers are tied across the track by iron rods. This has been used on some railways in England and on the continent of Europe.

Sir Macdonald Stephenson's chair and sleeper is made of punched and bent boiler-iron. The punchings form the slots in which the rails are slipped, and the displayed flanges of the plate form the foot which rests on the ballasting.

Parkins' continuous sleeper for railway-rails, patented in England in 1835, was made of earthen blocks, molded and baked, laid in continuity, tongues and recesses on adjacent blocks serving to lock them together. Samuel's cast-iron, wooden-cushioned sleeper is 42×16 inches, and requires from 100 to 133 tons (of 2,240 pounds) per mile, according to the width of the intervals.

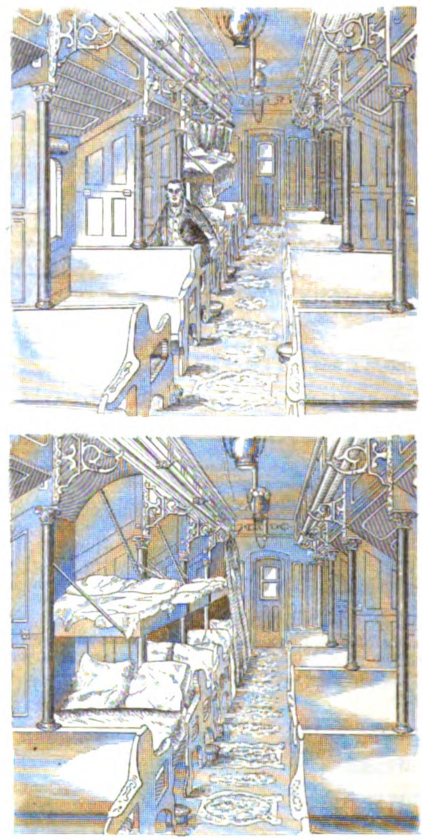
De Bergue's cast-iron sleeper is 20×14 inches, weighs 46 to 56 pounds; each gives nearly two square feet of bearing, requiring 100 tons (of 2,240 pounds) per mile, to give a bearing of $1\frac{3}{4}$ square feet per foot of track. With 20-feet rails, and blocks spaced 30 inches, center to center, this plan requires 22,124 pieces per mile. It was tried in England on several lines.

5. (*Weaving.*) The upper part of the heddle of a draw-loom through which the threads pass.

6. (*Railway.*) Short for Sleeping-car (which see).

Sleep'ing-car. (*Railway.*) A car arranged with berths for passengers during night travel. The seats

Fig. 5178.



Sleeping-Car.

are usually convertible into a lower berth, while an upper berth is let down from the roof.

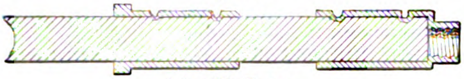
Sleep'ing-ta'ble. (*Metallurgy.*) An apparatus (*tables dormantes* or *jumelles*) consisting of an inclined plane (two such are generally arranged alongside each other), upon which finely pounded ore is washed to concentrate it.

The ore is stirred into a thin mud in a cistern at the head of the incline, and is then allowed to flow in a thin stream, which spreads to a width equal to that of the table: the heavier particles settle first, and the lighter matters pass farther down. The operation is facilitated by brushing the slimes from the lower toward the higher end, which allows the water to wash out light matters which have become entangled in heavier portions of the ore. It is called a *sleeping-table*, because, unlike the *percussion-table*, the *rack*, *frame*, *jigger*, etc., it has no motion.

Sleeve. A tube into which a rod or another tube is inserted. If small, it is often called a thimble; when fixed, and serving merely to strengthen the object which it incloses, it is a reinforce. In the majority of its applications, however, the two parts have more or less relative circular or longitudinal motion.

The example (Fig. 5179) is an axle fitted with sleeves or bushings of brass, which are slipped on

Fig. 5179.



Axle with Sleeves.

the spindle and confined by punching down the brass into countersinks in the spindle. The inner bushing carries a butting collar.

Sleeve-ax′le. A hollow axle running upon an axial shaft.

Sleeve-coup′ling. A tube within which the abutting ends of shafting are coupled together.

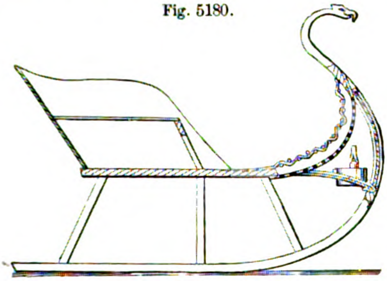
Slee′zy. (*Rope-making.*) Rough from projecting fibers, as yarn or twine made of inferior material.

Sleid. See SLEY.

Sleigh. (*Vehicle.*) A pleasure or passenger vehicle on runners. A somewhat finer vehicle than a *sled.*

Fig. 5180 is a sled with a lamp-stove in front for warming the feet.

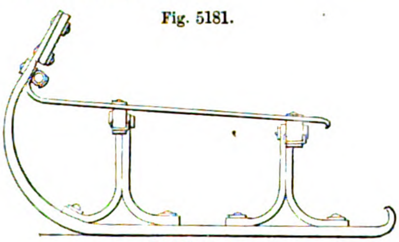
Fig. 5180.



Jumper.

Fig. 5181 is a sleigh-frame, and shows a mode of construction with bent stuff and bolts.

Fig. 5181.



Sleigh-Frame.

Sleigh-bell. A small bell of globular form attached to sleigh harness. The clapper is a ball of iron or bronze.

Fig. 5182.

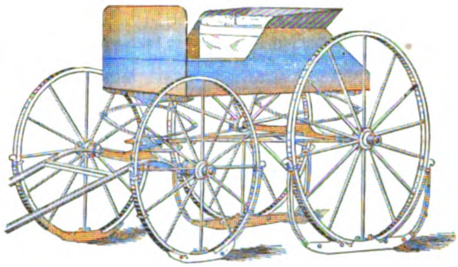
Sleigh-Bells.

Sleigh-brake. See SLED-BRAKE.

Sleigh-run′ner. (*Vehicle.*) One of the curved pieces on which a sleigh slides. See SLEIGH; SLED.

The example shows runners temporarily attached to the wheels of a buggy to make it slide upon snow or ice. The wheels are locked by means of spring straps.

Fig. 5183.



Sleigh-Runner.

Slew′ing. (*Ordnance.*) In serving land artillery, turning the piece on the spot where it stands, equivalent to *training* on shipboard.

Sley. 1. (*Weaving.*) A weaver's *reed.* A frame of parallel vertical slats, between which the warp-threads are passed. The *sley* is mounted in the *batten* or *lathe;* the slats passing between the warp-threads beat the *weft-threads* against the *web* when the batten is swung. See HAND-LOOM.

2. (*Knitting-machine.*) The guide-way of the *slur* or carriage. Any guide-way in a knitting-machine.

Slice. 1. (*Furnace.*) *a.* The instrument used for clearing the air-spaces between the bars of the furnace when they become choked with clinkers.

b. A *peel* or fire-shovel.

2. (*Nautical.*) *a.* A bar with a chisel or spear-shaped end, used for stripping off sheathing or planking.

b. A spade-shaped tool used in flensing whales.

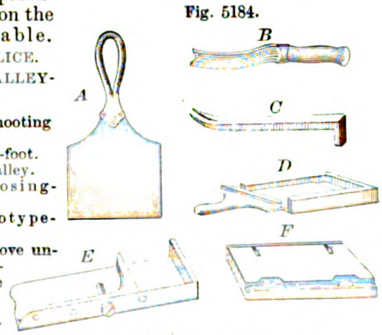
c. A wedge driven between the false keel and the bilgeway, to raise a vessel before launching.

3. (*Printing.*) *a.* A kind of paddle (*A*, Fig. 5184) used for spreading ink upon the inking-table. See INK-SLICE.

b. See GALLEY-SLICE.

B is a shooting stick.
C, sheep's-foot.
D, slice-galley.
E, composing-stick.
F, stereotype-block.
See the above under their respective heads.

Fig. 5184.



Printer's Slices, Sticks, etc.

4. (*Household.*) A broad, thin knife for serving fish at table.

5. (*Pharmacy.*) A round-ended, pliable knife for spreading plasters. A *spatula.*

Slice-bar. (*Furnace.*) A hooked poker for removing slag and cinders from grate-bars of furnaces.

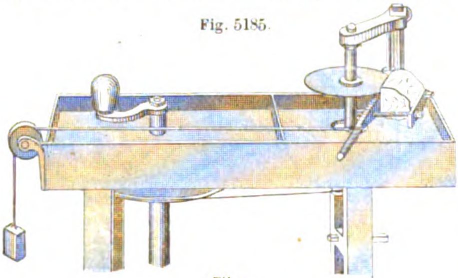
Slice-gal′ley. (*Printing.*) A galley having a movable false bottom or *slice.* *D*, Fig. 5184.

Sli′cer. 1. (*Gem-cutting.*) The circular saw of the lapidary. It is a disk of sheet-iron, revolving in a horizontal plane, and usually about 8 or 9 inches in diameter and $\frac{1}{200}$ inch in thickness. To give it sufficient rigidity, it is hammered into a slightly concave form, about $\frac{1}{8}$ inch in the entire diameter. This does not prevent the cutting of a straight section, as the commencement of a cut is in one plane and the trifling curvature gives way, being flattened

by the kerf it has cut, and in which it is compelled to run.

The slicer is firmly clamped, like a circular saw, between two flanges on its spindle, which is made of such a length that the edge of the slicer may be about three inches above the level of

Fig. 5185.



Slicer

the bench. Diamond-dust moistened with water is employed as an abradant during the cutting process.

In the illustration, the slicer is shown as mounted on the lapidary's bench and the stone mounted on a *crane* which keeps it constantly fed up to the *slicer*. The latter is *seasoned*, and plied with diamond-dust and lubricated with oil of brick.

Slic'ing-ma-chine'. (*Pottery.*) A machine which acts as a substitute for the hand operations called SLAPPING or WEDGING (which see).

It is a kind of pug-mill with an upright axis and cylinder armed with stationary and revolving knives respectively, to cut and masticate the clay. The spiral blades act as a screw, and force the clay out of a lower aperture, where it is sliced into prisms and thrown back into the mixer for a repetition of the process.

In China, the clay is trodden by human feet or by oxen. In various parts of Europe, it is trodden by the feet or worked by mallets or pounders.

Slick. 1. (*Joinery.*) A wide-bitted chisel, used by framers in paring the sides of mortises and tenons.

2. (*Metallurgy.*) A metalliferous slime.

Slick'en-sides. (*Mining.*) *a.* Specula galena, occurring in seams which split asunder when struck by the miner's pick. A Derbyshire term.

b. A seam of clay intersecting a lode and causing a vertical dislocation. Called also *slide*.

Slick'er. 1. (*Leather-working.*) A tool of steel or glass inserted in a wooden stock and used upon leather in process of manufacture.

Fig. 5186.

Slicker.

The steel *slicker* or *stretching-iron* is rounded off at the corners and scraped upon the surface of the leather, under a strong pressure, to remove lumps and inequalities and stretch the leather.

The glass *slicker* is used in rubbing in the coat of size and tallow, in the surface finishing of the leather.

Treating hides with a slicker during the process of currying is shown in the ancient paintings of Kourna, Thebes.

2. (*Founding.*) Or *sleecker*. A small tool, generally of brass, the polished surface of which forms a curve of some kind. Slickers are of various shapes; they are used to slick down the curved surfaces of molds after withdrawal of the pattern, or after blacking, as the trowel adapts itself to the flat parts. The short handle of these tools is a stud at the back, and projects at right angles to the face. The different forms are known as *half-rounds*, *egg-slicker*, *button-slicker*, *angle-slicker*, etc., etc.

Slick'ing. 1. (*Mining.*) A narrow vein of ore.

2. (*Hat-making.*) The attaching of the fur *nap* to the felt body.

Slide. 1. An inclined plane down which logs are driven to a lower level.

The timber slides of the Alpnach in Switzerland are remarkable.

The log chutes of the Ottawa occur occasionally on 200 miles of that river, to avoid stoppage of the logs on the riffles.

2. (*Steam-engine.*) The guide-bars of a box or cross-head.

3. A slip of glass, usually 3×1 inches, on which a microscopic object is mounted. The thin glass for covering the object is made from $\frac{1}{50}$ to $\frac{1}{250}$ of an inch thick. Glass slides are usually of *flatted crown*.

4. A sliding shutter to an aperture, as of a dark-lantern.

5. (*Ordnance.*) The lower part of a ship's carronade or howitzer carriage, on which the top carriage rests and is run in and out. It corresponds to the chassis of a land-fortification carriage.

Slide-box. (*Steam-engine.*) A slide-valve chest.

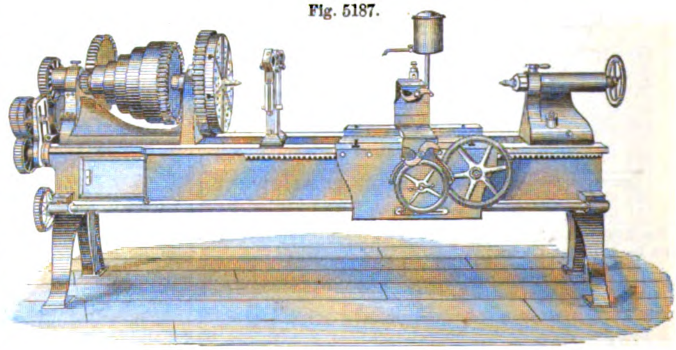
Slide-case. (*Steam-engine.*) The chamber in which the sliding valve operates.

Slide-head. (*Machinery.*) A device for supporting a tool or piece of work in a lathe, etc.

Slide-lathe. The lathe of the metal-worker, in which the tool-rest is caused to traverse the bed from end to end by means of a screw.

That shown (Fig. 5187) has the screw cutting and turning feeds so arranged that one may be changed for the other. The

Fig. 5187.



Slide-Lathe.

larger sizes have a compound slide-rest and automatic cross-feed. The bottom rest has a quick hand traverse, and the screw is supported throughout its length. See SCREW-CUTTING LATHE, etc. See lists under LATHE; METAL-WORKING TOOLS. See also SLIDE-REST.

Slid'er. 1. (*Vehicle.*) A bar which unites the hind ends of the fore hounds and slides under the coupling-pole.

A double slider has a bar above and below the coupling-pole. Called also *sway-bar*.

2. (*Locksmithing.*) A horizontally moving tumbler.

Slide-rail. (*Railway Engineering.*) *a.* A contrivance used in England for shunting cars. A *railway-slide*. It consists of a platform on wheels running transversely across the tracks, and carrying a car from one line of rails to another without *switching*.

b. A switch-rail.

Slide-rest. (*Machinery.*) A tool-rest employed

for lathes, planing-machines, etc., in which the tool is securely clamped to a plate capable of motion in one or several directions by means of screws.

In 1648, engravings published at Rome by Maignan show lathes for turning the surfaces of mirrors, in which the tool was guided by frames so adjustable as to form plane, spherical, or hyperbolical surfaces.

The wheel-cutting engine and fusee-cutting engine of Dr. Hooke, invented about 1655, had mechanical devices for guiding the tools. These, as well as the screw-cutting lathe of Hindley, 1741, and other machines having similar contrivances, were particularly constructed for the use of clockmakers, who were the first to employ special machines in their business.

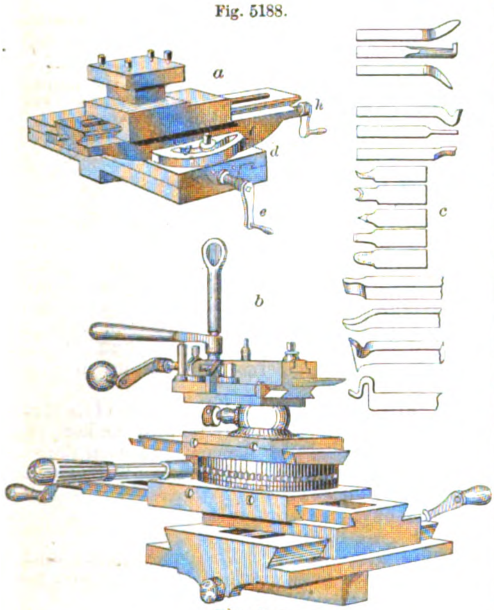
The first instance of the true slide-rest is shown in the French Encyclopédie. This very nearly corresponds with that usually employed in lathes for amateurs by London makers. It was adapted to the purposes of machinery by General Sir Samuel Bentham, who attached it to lathes built for the British Admiralty previous to 1800. The slide-rest is the origin of the planing-machine for metal. Bentham was also the inventor of the first planing-machine for wood, patented in England in 1791, but invented by him in Russia some years previous. The slide-rest is described in his patent of 1793.

Nasmyth ascribes the invention of the automatic slide-rest to Henry Maudslay, who certainly greatly improved the lathe. Maudslay was the pupil and workman of Bramah, and the instructor of Nasmyth and Clements.

Before the invention of the slide-lathe, the turning-lathe depended for its accuracy upon the steadiness of the muscles of the workman. By fixing the turning tool in a rest which is movable accurately in one or another direction, or a line compounded of the two, mathematical accuracy of workmanship is obtained. Bramah himself patented a slide-rest in 1794.

In Fig. 5188, *a* is a slide-rest for the foot-lathe. It has a feather fitting between the two cheeks of the lathe-bed, to which it may

Fig. 5188.



Slide-Rest.

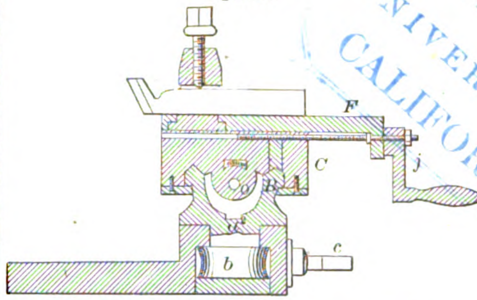
be firmly secured by a bolt. The sliding-plate *d* may be moved laterally by the handle *e*, which turns a screw; the slide *f* may be adjusted angularly by means of the slotted arc and nut *g*, and carries the rest, which is moved longitudinally by a screw and handle *h*. The tool, being clamped in the holder, may be moved in a longitudinal, transverse, or circular direction, as required by the character of the work.

b is the *spherical slide-rest*. This is provided with two additional slides for greater facility of adjusting the tool-holder to varying changes of position required in operating on curved and irregular forms.

c are tools used with the side-rest in hand and power lathes.

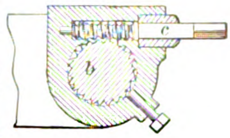
In Fig. 5189, the point of the tool is set at any desired angle with the axis of the lathe by a worm *c* engaging a worm-wheel *b* on the spindle a^2 projecting from the lower part of the bed *B*. The bed *B* and head *C* turn together, carrying with them the tool-holder *F*, which is advanced toward the work by a screw operated by the crank *j*.

Fig. 5189.



Slide-rod. (*Steam-engine.*) The rod which operates a slide-valve.

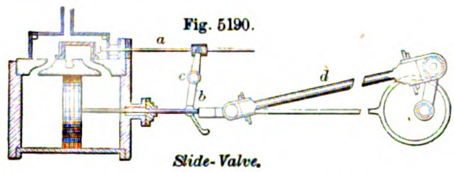
Slid'er-pump. A form of Rotary Pump (which see).



Slide-Rest.

Slide-valve. A valve which opens or closes by sliding over the port or ports. The valve-rod *a* is operated from the crank-shaft of the eccentric by an intermediate lever *b* pivoted at *c*; as the pitman *d* advances by the down stroke of the piston, the valve is drawn back, open-

Fig. 5190.



Slide-Valve.

ing the lower port, which then becomes the eduction-port, and *vice versa*.

The *long slide*, of large condensing-engines, is a slide-valve of such length as to govern the ports at the ends of the cylinder, and thereby bring them alternately in connection with the middle or bridge part at which the steam is inducted, and with the open part of the valve-chamber, which has a connection, through the hollow back of the valve, with the eduction passage to the condenser. The long slide was invented by Murdoch, of the firm of Boulton and Watt.

The slide-valve was substituted for the steam-cock by Murray, of Leeds, England, in 1810.

The slide-valve is placed in the steam-chest to work over the steam-ports by which live steam from the boiler is admitted to the cylinder, and exhaust steam from the latter is allowed to pass to the condenser or to atmosphere, as the case may be. Its form is arched, and it has a flat face all round, which works steam-tight on the valve-seat.

The arched cavity in the valve is constantly in connection with the steam-induction pipe *s*, and the live steam from this cavity is alternately admitted at the ports *a* and *b* as the valve shifts. Fig 5191.

In the three figures the valve is shown *in situ* at the respective ends of its stroke and detached.

At *A*, the steam admitted at *s* passes by the port *b* below, and elevates the piston, the latter driving before it the exhaust steam, which is educted at the port *a*, and passing through or around the valve, departs by way of the escape-pipe *e*, which is secured by flanges and bolts *o p* to the end of the steam-chest.

The valve-rod *t* is secured by a collar and nut *d* to the valve, and passed through a stuffing-box in the cap *m* of the steam-chest.

While the faces *h* of the valve slip upon the seat, the back of the valve has depressions *k k*, which contain a packing, so as to bear against the top plate of the chest.

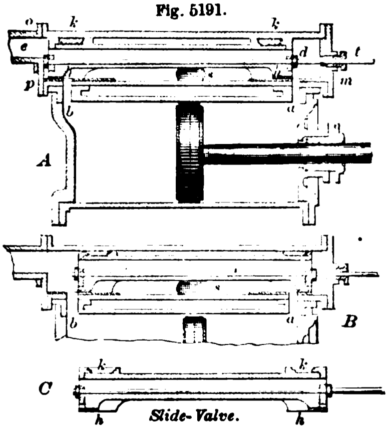
B shows the valve at the other end of its stroke, the port *b* being the eduction, and the port *a* the induction.

C shows the valve detached and destitute of packing in the recesses *k*.

The *balanced* slide-valve, so called, is one in which the steam pressure which keeps the valve on its seat is partially relieved by an upward pressure of steam on the under side, or by a plate, which prevents access of steam to the larger portion of the upper area of the valve.

The *lead* is the width of opening of the steam-port when the

Fig. 5191.



piston is at the end of its stroke. It may be effected by turning the eccentric on the axle a little in front of the crank.

The *lap* is *inside* or *outside*. The former is the difference between the width of the shell part of the valve and the distance between the inside edges of the adjacent ports. The *outside lap* is the excessive breadth of the valve over the width over all the ports.

The *travel* is the length of stroke of the valve.

The *setting* is the arrangement of the eccentric to give the requisite *lead*.

Slide-valve Cal'cu-lat'or. Caldwell's slide-valve calculator is a table with vertical, radial, and circular lines, and a revolving templet, giving all calculations relating to the action of the slide-valve. The following points may be deduced by its use, being read off at sight: —

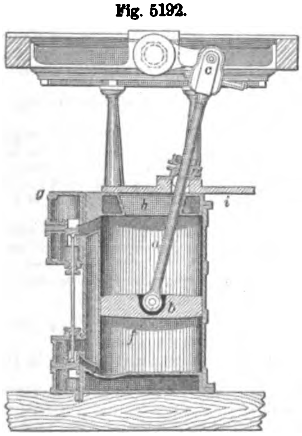
1. The proper travel of valve to produce certain results.
2. The proper lap to cut off at given part of stroke.
3. The proper lap to exhaust at given part of stroke.
4. The proper lap to cushion at given part of stroke.
5. The proper lap to cut off equal on each side of piston.
6. The proper lap to exhaust equal on each side of piston.
7. The proper lap to cushion equal on each side of piston.
8. The proper width of exhaust port to prevent back pressure.
9. The proper lead to give the valve.
10. The proper amount of opening for admission of steam.
11. The position of eccentric on shaft.
12. The relation of valve to piston at every part of stroke.

These points are ascertained at sight.

Slid'ing-cov'er Steam-en'gine. Parkyn's sliding-cover steam-engine (English) has an oscillating piston-rod connected directly to the crank-pin.

a is the piston-rod, which also serves as a connecting-rod, being attached at the lower end to the piston *b*, and at its upper end to the crank-pin *c*. *d* is a recess in the piston *b* for the reception of the lower end of the rod *a*, which is united to the piston by a cross-pin *f*.

Fig. 5192.



Sliding-Cover Engine.

As the rod *a* oscillates in a vertical plane according to the motions of the crank, an elongated slit *h* is made in the cylinder-head *g* in a line parallel with the crank. Over this is a supplementary, steam-tight cover *i*, which slips back and forth on the head *g*, in accordance with the varying positions of the crank and connecting-rod. The upper portion of the stuffing-box has two arms, which turn in suitable bearings in the sliding-cover as the latter moves to and fro.

This is one form of *direct-action steam-engine*, and was invented to avoid the use of the beam in marine engines.

Slid'ing-gage. An instrument used by mathematical-instrument makers for measuring and setting off distances.

The gages used by carpenters and artificers generally are on the sliding principle, though some instruments to which the term "gage" is applied turn on a joint, and others are rigid and immovable in their parts.

Slid'ing-gun'ter. (*Nautical.*) A mast with means for mounting on the after side, used with royals, skysails, etc.

Slid'ing-keel. (*Nautical.*) A movable keel capable of being extended below the usual one, to allow the vessel to carry more sail and to diminish the leeway, and to give to a flat-bottomed vessel or one of small draft the steadiness under sail of a vessel of considerable depth of hull.

The *lee-board* has for many years been used by the Dutch navigators, being launched over the lee side of a vessel to prevent drifting when sailing on a wind.

At what period the lee-board was transferred from the lee side to the center, being lowered in a fore-and-aft well amidships, is not known to the writer. It was introduced into England by Admiral Schank, probably from Holland, and was first applied to a government exploring-vessel destined for New Holland. The wide and strong board which formed the sliding-keel was connected to three vertical planks, which slipped up and down in wells, and were raised and lowered by racks and pinions.

Willoughby made a massive iron keel suspended by iron bars, which slipped in vertical wells amidships. The bars were worked by racks and pinions, as before. The heavy keel acted as ballast.

Shuldham's metallic sliding-keel (English) is of a somewhat triangular shape, and is pivoted at its apex forward. When lowered, the after end is deepest in the water, and resembles the ventral fin of a fish. It moves in a longitudinal well amidships, passing through the true keel. See CENTER-BOARD.

Slid'ing-pul'ley. (*Machinery.*) A kind of coupling in which the band-pulley is slipped into or out of engagement with an arm firmly attached to the shaft and rotating therewith.

Slid'ing-rule. A scale having two graduated parts, one of which slips upon the other. The numbers are so arranged that when a given number on one scale is made to coincide with a given number on the other, the product or some other function of the two numbers is obtained by inspection. It is used for gaging and mensuration. See GUNTER'S SCALE.

Slid'ing-scale. A rule with a sliding member. A *sliding-rule.*

Slid'ing-way. (*Shipbuilding.*) One of the structures on each side of and parallel with the keel, supporting the bilgeways of the cradle whereon the vessel rests in launching. The sliding-ways are the inclined planes down which the vessel slides, and are made of planks 3 or 4 inches wide, laid on blocks of wood. See LAUNCH.

Slime. (*Metallurgy.*) The common name among miners for the mud obtained by wet grinding or stamping the ores of the precious metals.

Slime-pit. (*Metallurgy.*) A reservoir in which water passes slowly to its exit, depositing metalliferous slime. A *labyrinth.* A *buddle-hole.*

Slime-sep'a-rat'or. (*Metallurgy.*) A machine for operating upon slime or metalliferous mud from the stamping-mill. The slime is disseminated in an ascending current of water which floats upward the lighter portions, while the metalliferous matters sink to the bottom. See SEPARATOR.

Sling. 1. (*Weapon.*) A short leathern strap having a string secured to each end, by which a stone is hurled.

The stone lying in the strap, which has a central aperture to receive it, the sling is rapidly whirled, the ends of the two strings being held in the hand, and when one string is released, the stone flies off

at a tangent. The velocity is computed from the length of the radius and rate of revolution.

The sling is a weapon of great antiquity, and is still used among some barbarous nations. About 1406 B. C., when the first great dissension occurred among the Israelites, we read that among the 26,000 Benjaminites were "700 chosen men, left-handed; every one could sling stones at an hair-breadth and not miss." Young David was a skillful slinger.

The sling was used by the Phœnicians, Egyptians, and Persians. By the early Greeks it appears to have been but little known, but the light troops of the later Greeks and Romans consisted largely of slingers. The missiles were usually stones, but cast plummets were also used by the Greeks. Such are found on the plain of Marathon.

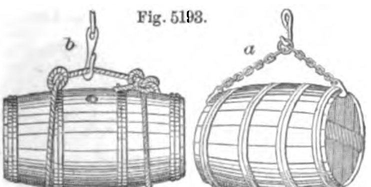
Stones hurled by hand without slings were often used. The Libyans carried three spears and a bag full of stones.

The inhabitants of the Balearic Isles were famous slingers in the time of Strabo.

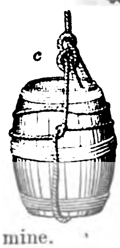
The Huguenots used slings at the siege of Sancerre, 1672, to economize powder.

2. (*Hoisting.*) A device for holding articles securely while being hoisted or lowered. It is usually

Fig. 5193.



Slings.



of rope, but frequently a chain having hooks at its ends and a ring, through which to pass the hook of the hoisting-rope, is employed, as *b*, Fig. 5193.

a c severally represent rope arrangements for slinging a cask on its side and in an upright position.

Fig. 5194 represents a sling for lowering or raising horses in the shaft of a mine.

Fig. 5194.

Horse-Sling.

For embarking or disembarking horses or cattle, the slings have a canvas band which forms a cradle for the animal.

3. (*Nautical.*) The chain, clamp, or rope which supports a mast. To sling the yards for action is to secure them at the slings by iron chains fitted for the purpose.

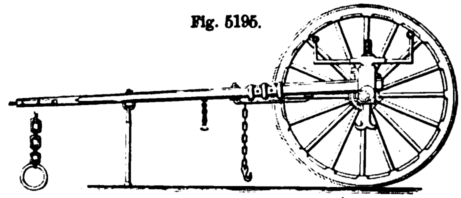
4. The strap by which a rifle is supported on the shoulder.

5. (*Surgical.*) A looped bandage or handkerchief placed around the neck to support a wounded arm.

Sling-cart. (*Ordnance.*) A two-wheeled vehicle used for transporting cannon, etc., short distances.

It has a strong, upwardly curved iron axle, through which passes a perpendicular elevating-screw. The

Fig. 5195.



Sling-Cart.

breech of the gun is slung beneath the axle and the muzzle beneath the pole, and it is raised from the ground by turning the screw.

A four-wheeled vehicle of substantially similar construction, called a *sling-wagon*, is used for transporting heavy blocks of stone, timbers, castings, shafts, and steam-boilers. The coupling-bar of the hind part of the wagon being elevated, the sling-chain is placed around the boiler; the coupling-bar being now pulled down, the chain winds on the hind axle and lifts the load. The bar is then secured to the fore carriage.

Sling-dog. An iron hook with a fang at one end and an eye at the other for a rope. Used in pairs for hoisting, hauling, rafting, etc.

Slip. 1. (*Hydraulic Engineering.*) An inclined plane on which a vessel in its cradle is supported while on the stocks building, or upon which it is hauled for repair. It may be considered that the inclined planes upon which the galleys and triremes of the ancients were hauled were *slips*. Also the planes on which they were hauled or launched at the *diolcos* or drawing-place on the Isthmus of Corinth, in their passage from the Corinthian to the Cenchræan Sea, avoiding the stormy and dangerous passage around the Peloponnesus.

Until the introduction of the heavy vessels of modern times, slips consisted of inclined planes about 220 feet in length, the bottom projecting into the sea and terminating in a timber platform. The inclination or rise was equal to $1/14$ of the length, being about 5 inches in 6 feet. They were adapted for receiving vessels drawing 16 feet of water, which were lightened for the purpose.

Morton's slip (English), patented 1818, has been put down in many of the ports of Britain. Its chief feature is in placing a complete wheel-truck underneath the bottom of the vessel, the truck having a long, straight beam extending beneath the keel of the vessel, with blocks fitted upon it for the keel to rest upon. The support is blocked up to the keel, so that the latter is not strained when out of the water. The truck is borne by three parallel inclined rails by the intervention of numerous wheels. The ship is kept in perpendicular position by a cross-bearer, upon which are blocks adapted to the curvature of the sides of the vessel, forming a cradle. The slip is hauled up the inclined plane by tackle and capstans, pawls falling into a middle rack to sustain the purchase.

Clark's radiating railway for the repairing of vessels, New York, 1827, was of the nature of a turn-table, so that when a vessel was raised on the inclined water-slip and drawn on to the turn-table, it might be partially rotated and then slipped off to one of a circular series of slips, which might each be occupied by a vessel undergoing repair, while but a single slip sufficed for drawing up and launching.

2. A space between wharves or jetties, in which ships or ferry-boats may lie to receive or discharge cargo or passengers.

A ferry slip is usually provided with a landing platform, the landward extremity of which is attached to the edge of the quay by movable hinge-joints, admitting of its free vertical oscillation. The seaward extremity of this platform rests on a floating tank, and has the same elevation above the surface of the water as the deck of the ferry-boat. The outer extremity of the platform, which rests on the floating tank, is thus elevated or depressed with the rise and fall of the tide, but always remains on a level with the steamboat's deck, and affords during high-water a level road, and during low-water an inclined plane, for the passage of carriages and passengers between the vessel and the land.

3. (*Nautical.*) The difference between the speed of the propeller and that of the vessel, being due to the retreat of the resisting body under the impact of the propeller. The speed of the vessel being deducted from the speed of the propeller gives the *slip*.

Negative slip, as it is called, is when the speed of the vessel is apparently greater than that of the propeller. This occurs when, owing to the bad lines of the vessel, a body of dead water is created, which follows in the wake of the ship.

4. (*Porcelain.*) *a.* Fluid material for making porcelain. It consists of finely ground flint or of clay. The flint is calcined, stamped, and ground in water in a GRINDING-VAT (which see), a machine resembling the *arrastra*. Clay is mixed with water and mechanically divided until it makes a creamy fluid.

Slip is strained through silk sieves called *lawns*. A pint of slip weighs from 24 to 32 ounces, according to material. It is evaporated to the required consistence in pans, called *slip-kilns*, and then cut, pressed, and plasticized, by *slapping* or in a pug-mill, and stored in heaps or cellars to age or ripen.

b. The colored clays used to fill up the depressed pattern in the face of a tile, which is to be ornamented by encaustic.

5. (*Printing.*) Matter in column is printed from the *galley* on slips of paper, for revision and amendment, where the corrections are likely to be extensive, requiring additions or removals which would affect the paging.

6. (*Bookbinding.*) The end of the twine to which the sheets are sewed, serving to attach the book to the boards.

7. A leash.

8. A quantity of yarn.

9. The fine mud from a grindstone trough.

10. (*Mining Engineering.*) A dislocation of a seam or lead, destroying continuity. A *shift*. See FAULT.

Slip-dock. (*Shipbuilding.*) A dock whose floor slopes toward the water, so that its lower end is in deep water and its upper end above high-water mark. On the floor of the slip are four parallel rails to support the *cradle*. See SLIP, 1.

Slip-hook. (*Nautical.*) A hook which grasps a chain-cable by one of its links, and may be disengaged or *slipped* by the motion of a trigger, a sliding ring, or otherwise.

Slip-kiln. (*Porcelain.*) An oblong trough of stone or brick, bottomed with fire-tiles, and heated by a furnace beneath. Its length is 20 to 50 feet, breadth 2 to 6 feet, depth 8 to 12 inches. It is used for evaporating *slip* to a workable consistence, after which the clay is *milled;* that is, plasticized by working in a pug-mill.

Slip-knot. (*Nautical.*) A knot which slips around the line or rope around which it is made. A *slip-noose*.

Slip-link. A connecting link which allows a certain freedom of motion.

Slip'per. 1. A covering for the foot; it does not extend so high up as the ankle-joint, and is unprovided with a fastening, so as to be easily drawn on or off.

Slippers were commonly used by the Greeks and Romans (*crepida*). They were made to fit either foot indifferently. Boots were made rights and lefts.

2. A brake-shoe for a wheel in descending a hill.

Slip-rope. (*Nautical.*) A rope by which a cable is secured preparatory to slipping the cable.

Slip-shack'le. (*Nautical.*) One having a lever-bolt which may be let go suddenly when required.

Slip-stop'per. (*Nautical.*) Apparatus for suddenly letting go the anchor out of its lashings when it is required to drop it.

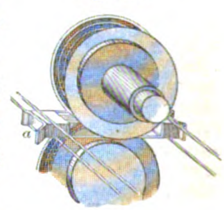
Slip-way. (*Shipbuilding.*) One of the pair of parallel, inclined platforms of timber, firmly founded on the floor of the slip and kept steady in their positions by shores. Their inclination varies from 1 in 12 for small ships to 1 in 24 for the largest. The breadth may be 4 feet and under, according to the size of the vessel. See LAUNCH.

Slit-deal Plane. (*Joinery.*) A tonguing or grooving plane.

Slit-nose Bit. See NOSE-BIT.

Slit'ter. A machine for shearing up sheet-iron into slips for nail-rods, etc. It has a series of steel disks with very sharp edges, with a groove between them of about two inches in depth, into which the disks of another roller fit. A piece of sheet-iron being passed through the guides *a* is divided into a number of strips corresponding to the number of grooves.

Fig. 5196.



Slitter.

Slit'ting-file. A file with two acute and two obtuse edges and parallel sides. Its cross-section is a rhomb, whose longer diagonal has, say, three times the length of the shorter one. A *lozenge*-shaped file.

Slit'ting-gage. (*Saddlery.*) A tool used to cut straps of any given width from the hide. Driving lines, reins, and all the various straps which go to form harness are thus cut from the sides of leather. The stem of the gage is marked in inches and eighths, and the set-screw holds it at the desired adjustment.

Fig. 5197.

Slitting-Gage.

Slit'ting-ma-chine'. 1. (*Metal-working.*) A machine for cutting plate-metal into strips for nail-rods or other purposes. Fig. 5196.

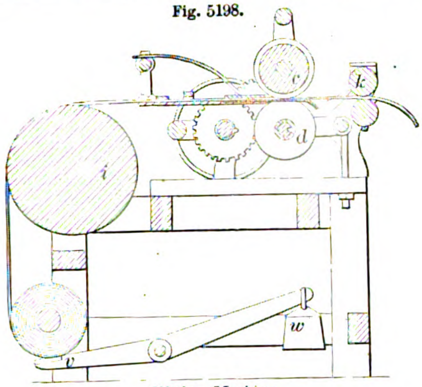
An apparatus of this kind is said to have been introduced by Godfrey Bochs, 1590.

It is related that a man named Foley, a fiddler, living near Stourbridge, first introduced slitting machinery into England from Sweden, where its employment gave great advantages to the Swedish nail-makers over their English brethren. He visited Sweden, and fiddled his way into the iron-works, where he managed to pick up a knowledge of the methods employed. Returning to England, he, with associates, erected a slitting-mill, but when everything was completed the machinery would not work. Nothing discouraged, Foley revisited Sweden in his rôle of fiddler, when he succeeded in obtaining lodgings within the works, where he had an opportunity of making rough drawings of the machinery, with which he returned to England and put his mill in successful operation.

The construction of the machine is essentially similar to that of the iron-rolling machine. Two spindles carry a series of steel-faced disks, which work against each other, dividing thin plates of iron about 6 inches wide into a number of rods, from which the nails are made. Similar rods are also made of larger sizes. They always exhibit two ragged edges, and from the fact of being put up in bundles, they are frequently termed bundle-iron.

2. (*Leather.*) A machine for cutting leather into strips or thongs. That illustrated is designed for dividing wide strips into narrow ones to be used in shoe-binding. The strip is wound upon a roller, passes over a drum *i* on to a table and beneath a flat guide, where it is presented to the action of a series of cutting-disks *c d*, and is divided into ribbons which are drawn through two rollers, shown at *k*.

Fig. 5198.



Slitting-Machine.

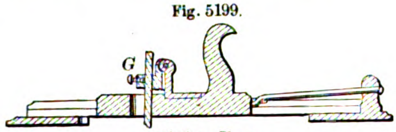
A lever *v* with weight *w* keeps the strip taut while being unwound.

Slit'ting-mill. 1. (*Gem-cutting.*) A very thin sheet-iron disk, the edge of which is charged with diamond-powder and lubricated with brick-oil, mounted on a stand and revolved by a treadle or otherwise. Used by lapidaries in *slicing* or *slitting* gems, stones, porcelaneous shells, porcelain, and other materials, previous to grinding and polishing. See LAPIDARY'S MILL.

2. (*Metal-working.*) A machine in which iron plates are slit into nail-rods. See SLITTING-MACHINE.

Slit'ting-plane. (*Carpentry.*) A tool for cutting boards, etc., into strips. In the example, the board is cut into thin slices by being passed under

Fig. 5199.

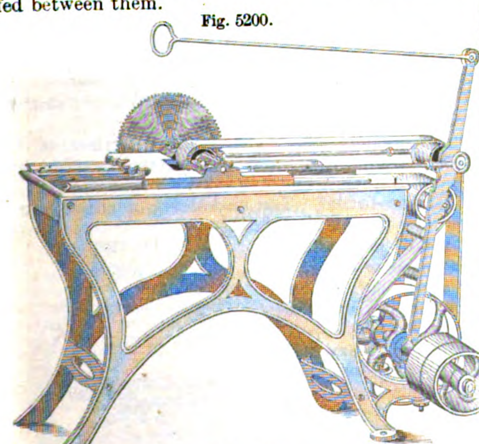


Slitting-Plane.

a cutter *G* arranged vertically to a hinged holder on a sliding stock moving on ways at each end and having a retracting spring.

Slit'ting-roll'er. One of a pair of coäcting rollers, having ribs which enter intervening spaces on the companion rollers, and cut into strips material fed between them.

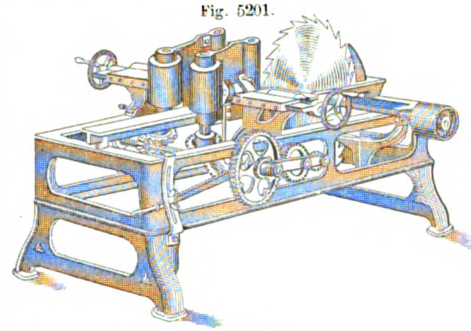
Fig. 5200.



Slitting-Saw

Slit'ting-saw. (*Wood-working.*) A machine for slitting scantling, boards, etc., into thin planks. It is provided with self-acting feed-rollers and adjustable table, and is, in general construction, similar to the RESAWING-MACHINE (which see). It fre-

Fig. 5201.

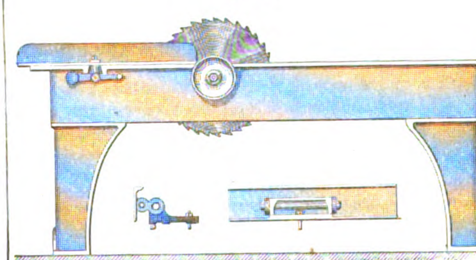


Slitting-Saw.

quently has a gang of saws for sawing the second way, and is applicable to a variety of uses, such as making lath, pickets, blind-slats, etc., from the bolt, effecting a great saving in labor over the ordinary method of doing such work with a single saw.

Fig. 5201 is a geared machine of this class, adapted for heavier work than that illustrated in the preceding cut, and Fig. 5202 a machine having a hand-feed.

Fig. 5202.



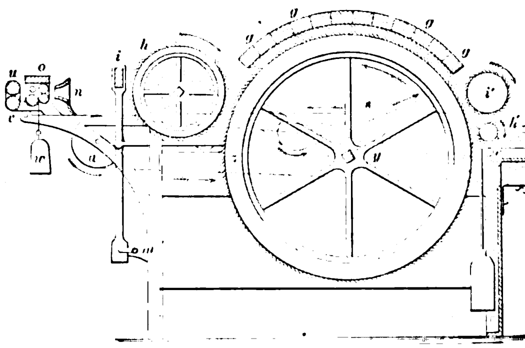
Slitting-Saw with Hand-Feed.

Sliv'er. (*Fiber.*) A continuous strand of cotton or other fiber in a loose, untwisted condition, ready for *slubbing* and *roving*, preparatory to being spun. The process is effected by the *finishing-card.*

The carding-machine (Fig. 5203) receives the roller from the lapping-machine in the grooves *a*, resting at the same time upon the roller *b*, which turns it by friction, so as to unwind the fleece or *lap*. This is conducted over the table *c*, between the two nipping or feed rollers *e*, where it is caught by the card-drum *z*, covered with the card-cloth in strips, parallel with its axis; *h'* is the *small runner*; *i'*, the *large runner*; *g g g g*, the flat *top-cards*; *h*, the *doffer-card*, which takes the fleece off the main drum, and which in turn is cleared by the *doffer-knife i*. This knife receives a very fast up-and-down motion from the crank *m*, by which it peels a gossamer-like fleece from the doffer-card. It is actually a comb, with very fine teeth, which penetrate slightly between the wire of the card as it moves downward. The fleece thus separated from the card is then drawn together through the tin funnel *n*, so as to form a narrow band or *sliver*, and is thus presented to the *drawing-rollers* at *o*. The front pair of these, being driven with a slightly greater velocity than those behind, draw the sliver through faster than it is delivered by the latter, and by this means attenuate the same. This action brings about a still greater parallelism of the fibers, which is repeated in every subsequent machine. The top rollers are pressed down upon the lower ones by the weight *w*. The rollers *u v* deliver the drawn sliver into cans, ready for the drawing and doubling process.

Sliv'er-box. The machine in which slivers of

Fig. 5203.



Finishing-Card.

long-stapled wool are lapped on each other and then elongated. It is like the drawing-frame of the cotton manufacture, except that the slivers of worsted being made by hand-cards, taper toward each end and are not continuous. Each sliver is laid upon the one preceding, so that its end reaches to the middle of the one in advance. The rate of acceleration of the relative speeds of the pairs of rollers is such as to make a uniform sliver eight times the length of the slivers as fed into the first pair of rollers.

Sliv′er-ing-ma-chine′. (*Wood-working.*) A machine for cutting splints, slivers, or shreds of wood for various purposes.

a. Narrow thin slats for making woven window-blinds in which slats form the weft.

Slats or scaleboard of thin wood, capable of being worked up into boxes for millinery, collars, small fruit, and what not.

Splints for making up into baskets.

Free's machine for cutting slats for blinds has a knife set in a reciprocating stock, which moves below the block to be worked; the knife-carriage on its return strikes a lever connected to a pawl that operates gear-wheels to feed down the block of wood for the next cut. See SLAT-MAKING MACHINE.

b. Finely shredded wood to serve as a substitute for curled hair for upholstery purposes. Known as *excelsior*.

Machines for slivering wood into small shreds, called *excelsior*, usually make two cuts; one to sever a scale, and the other to split the scale into shreds. Taggart's machine, January 23, 1866, has a rotary annular plane with a series of plane-bits and scoring-cutters thereon, and above which is a cylinder having a series of block-holders, so arranged that the blocks will fall on the annular plane after the action of each plane-bit and scorer, so that the whole block will be cut and scored into fine fibers.

Brooks and Clements' excelsior machine, March 25, 1868, is also a rotary shredder. The bolt is pressed downward within its fixed case by a weighted lever, and subjected to the action of the scoring and plane cutters at the upper surface of the horizontal rotating wheel. See Fig. 1897, page 815.

Sloam. (*Mining.*) A layer of earth between coal-seams.

Sloates. (*Vehicle.*) The cross slats in the frame forming the bottom of a cart or wagon bed.

Sloop. (*Nautical.*) *a.* A fore-and-aft rigged vessel with one mast, like a cutter, but having a jib-stay and standing bowsprit, which the cutter has not.

b. Formerly a ship of war of a size between a *corvette* and a *brig*.

War-vessels of 2,000 tons and upward, as large as line-of-battle ships in the days of Howe and Nelson, carrying 12 to 22 heavy guns, are now termed sloops.

Slop. (*Pottery.*) See SLIP.

Slope. 1. (*Civil Engineering.*) An inclined bank of earth on the sides of a cutting or an embankment. The slope is of varying angle, according to the nature of the soil and the hight of the slope.

The allowance is about as follows: —

Gravel, sand, or common earth, cuts, or banks, of less than 4 feet	1	base to 1 vertical.
Clay, cuts, or banks of less than 4 feet	2	base to 1 vertical.
Earth, of mixed sand and clay, cuts, or banks of 4 to 15 feet	1½	base to 1 vertical.
Pure gravel or sand, cuts, or banks of 4 to 15 feet	2	base to 1 vertical.
Clay, in banks of 4 to 15 feet	2	base to 1 vertical.
Stratified clay and sand, cuttings of 4 to 15 feet	3	base to 1 vertical.
Broken rock, in banks over 15 feet high	1½	base to 1 vertical.
Earth, of mixed sand and clay, cuts, or banks over 15 feet high	2	base to 1 vertical.
Pure gravel or sand, cuts, or banks over 15 feet high	2	base to 1 vertical.
Clay, cuts, or banks over 15 feet high	3	base to 1 vertical.
Stratified clay, in cuttings over 15 feet high	3 to 4	base to 1 vertical.

A *revetment* or retaining wall at the base of the slope saves excavation. The natural, strongest, and ultimate form of a slope is a curve, in which the flattest portion is at the bottom. Cultivation, sodding, and draining are preservatives.

Table representing the ratio of the horizontal to the perpendicular of certain angles of slopes: —

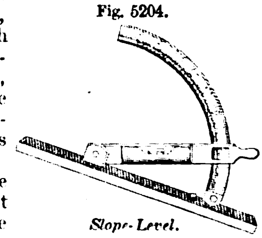
Angle.		
75° 58′ =	¼	horizontal in 1 perpendicular.
63° 28′ =	½	horizontal in 1 perpendicular.
53° 8′ =	¾	horizontal in 1 perpendicular.
45° =	1	horizontal in 1 perpendicular.
38° 40′ =	1¼	horizontal in 1 perpendicular
33° 42′ =	1½	horizontal in 1 perpendicular.
29° 44′ =	1¾	horizontal in 1 perpendicular.
26° 34′ =	2	horizontal in 1 perpendicular.
23° 58′ =	2¼	horizontal in 1 perpendicular
21° 48′ =	2½	horizontal in 1 perpendicular.
19° 59′ =	2¾	horizontal in 1 perpendicular.
18° 26′ =	3	horizontal in 1 perpendicular.
17° 6′ =	3¼	horizontal in 1 perpendicular.
15° 56′ =	3½	horizontal in 1 perpendicular.
14° 55′ =	3¾	horizontal in 1 perpendicular.
14° 2′ =	4	horizontal in 1 perpendicular.
13° 15′ =	4¼	horizontal in 1 perpendicular.
12° 32′ =	4½	horizontal in 1 perpendicular.
11° 53′ =	4¾	horizontal in 1 perpendicular.
11° 19′ =	5	horizontal in 1 perpendicular.
10° 47′ =	5¼	horizontal in 1 perpendicular.
10° 18′ =	5½	horizontal in 1 perpendicular.
9° 52′ =	5¾	horizontal in 1 perpendicular.
9° 27′ =	6	horizontal in 1 perpendicular.

2. (*Mining.*) The dip or inclination of a stratum or vein of ore.

3. (*Fortification.*) The inclined surface of the interior, top, or exterior of a parapet or other portion of a work. See PARAPET.

Slope-lev′el. The slope-level or clinometer is used for determining the angle of embankments, the grade of roads, pitch of roofs, fall of water-courses in some cases, and, by sights on the base-piece, may be adjusted to measure angles of elevation.

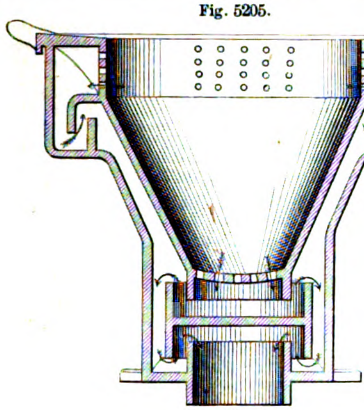
Fig. 5204.



Slope-Level.

Slop-hop′per. The basin of a water-closet or sink. The example

Fig. 5205.



Slop-Hopper.

shows one whose inner hopper has a marginal trap in a trough of the casing and a lower one in the double cup, whose recess beneath forms a trap over the exit-pipe. See WATER-CLOSET.

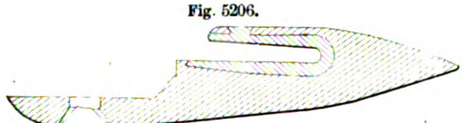
Slop-mold'ing. (*Brickmaking.*) As distinguished from PALLET-MOLDING (which see). In slop-molding, the mold is dipped in water before charging and the mold is usually carried by the off-bearer, who dumps the brick on the drying-ground. This is the English practice. Slop-molding, therefore, requires several molds; pallet-molding only one, as the molder dumps the bricks on to pallets, upon which they are carried off to the drying-ground.

Slop'ping. (*Pottery.*) The process of separating a mass of clay, or throwing the two halves together in a direction different from their former contact. It blends the materials of the mass and makes it homogeneous. It is also called *wedging* or *slapping*.

Slosh-wheel. (*Machinery.*) A wheel having two slots crossing at right angles and forming guides for two slides which traverse in them like the slides in a TRAMMEL (which see). A bar pivoted to the two slides makes two reciprocations in each direction for each revolution of the wheel.

Slot. (*Machinery.*) An elongated, narrow perforation or aperture. The slot in the finger or guard of a harvester is for the knife to play in, and its invention by Hussey marks one of the greatest advances in the invention of the reaper.

Fig. 5206.



Harvester-Finger.

Slot-drill'ing Ma-chine'. A machine for forming elongated holes by drilling instead of punching, as in the slotting-machine. The latter leaves the work in a rough and unfinished condition, while, when the former is used, no after-treatment with the file is required.

Fig. 5207 illustrates the machine employed in drilling the cotter-hole in a steam-engine cross-head.

The drill-spindle *a* is supported on a carriage *b*, to which the requisite traverse is imparted by connecting it to a stud on the face of a revolving disk, the extent of motion being determined by the distance from the center of the disk at which the stud is fixed.

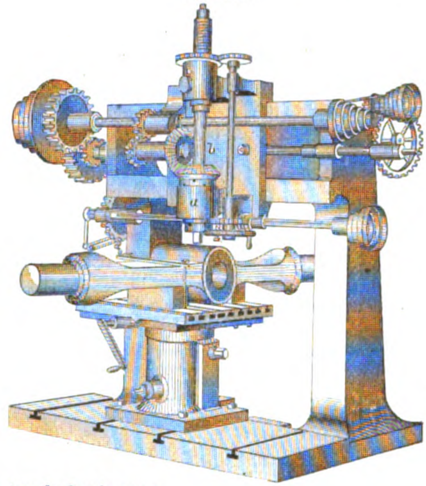
To insure uniformity of motion to the carriage, the pinion driving the disk is eccentric and the disk itself elliptical.

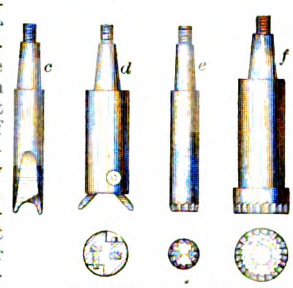
The drills *c d*, the latter having two loose cutters fixed by screws, and the rose-cutters *e f* for finishing, are employed in this machine.

Slot'ting-au'ger. One having side-cutting lips so as to make a slot in work fed laterally against it. See Fig. 459, Vol. I.

Slot'ting-ma-chine'. (*Metal-working.*) A variety of *planing-machine* in which the tool is vertically reciprocated while the work is fed beneath it between cuts. It is an outgrowth of the *key-groove* machine invented by Roberts. It has, however, two horizontal slides at right angles to each other and a circular adjustment or turn-plate, all three used in shifting the position of the work beneath the cutter,

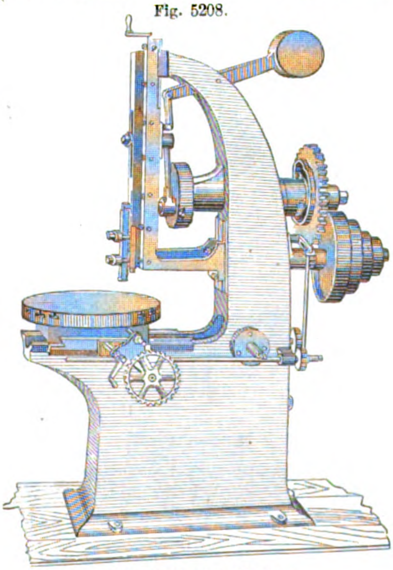
Fig. 5207.





Slot-Drilling Machine.

Fig. 5208.

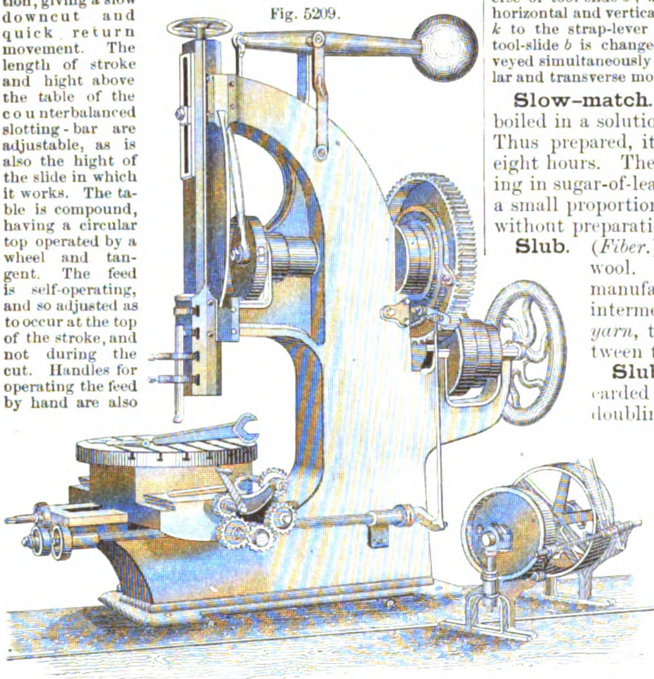


Sellers's Slotting-Machine.

and all three fitted with self-acting devices for feeding between the strokes of the cutter.

The machine (Fig. 5208) is provided with the Whitworth motion, giving a slow downcut and quick return movement. The length of stroke and hight above the table of the counterbalanced slotting-bar are adjustable, as is also the hight of the slide in which it works. The table is compound, having a circular top operated by a wheel and tangent. The feed is self-operating, and so adjusted as to occur at the top of the stroke, and not during the cut. Handles for operating the feed by hand are also attached to the machine.

Fig. 5209.

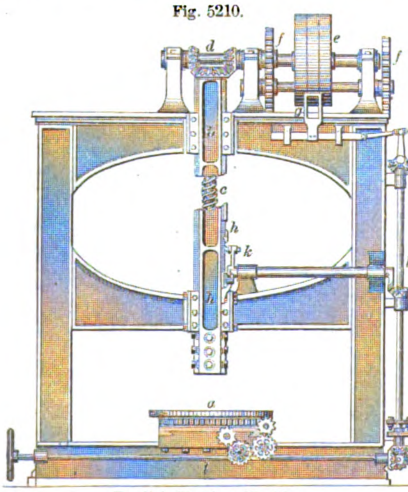


Slotting-Machine (New York Steam-Engine Company).

In the machine (Fig. 5209), the tool-holder has vertical adjustment by means of a hand-wheel and screw; the work-table has a hand as well as automatic feed, and the tool-holder may be reciprocated when desired by throwing the driving-pulley out of gear and turning a hand-wheel at the back of the machine on the pulley-shaft.

In the large English machine (Fig. 5210), *a* represents the work-table; *b*, the tool-slide, which has a slow downward and quick upward return motion; *c*, the guide-screw, taking into a nut on the back of the tool-slide; *d*, bevel-gears, the central one is keyed on the guide-screw *c*, the vertical ones receive motion from the two exterior pulleys at *e*, the central pulley is loose; *f f*, gears transmitting motion from right-hand pulley to right-hand bevel-wheel; *g*, strap-lever apparatus; *h h*, stops, which may be fixed any distance apart, according to the desired traverse of tool-slide *b*; *k*, lever, on which the stops *h h* act; *l l*, horizontal and vertical shafts for conveying motion from lever *k* to the strap-lever apparatus *g*, whereby the motion of the tool-slide *b* is changed; the motion thus derived is also conveyed simultaneously to the table *a*, whereby self-acting circular and transverse motions may be imparted to it.

Fig. 5210.



English Slotting-Machine.

Slow-match. Slightly twisted hempen cord boiled in a solution of distilled water and saltpeter. Thus prepared, it burns at the rate of one yard in eight hours. The rope may also be prepared by boiling in sugar-of-lead water, or by steeping in lye with a small proportion of quicklime added. Cotton rope without preparation may also be employed.

Slub. (*Fiber.*) A slightly twisted roving of wool. Like the *roving* of the cotton-manufacture, which occupies a condition intermediate between the *sliver* and the *yarn*, the *slub* of wool is intermediate between the *carding* and the yarn.

Slub′bing. Reducing the sliver of carded fiber to a uniform thickness by doubling and slightly twisting. The reduction of thickness of the sliver renders it so weak that the twist is required to make it hold together. The twist is given by rapidly revolving the can which receives the *slub* or *roving* from the drawing-rollers.

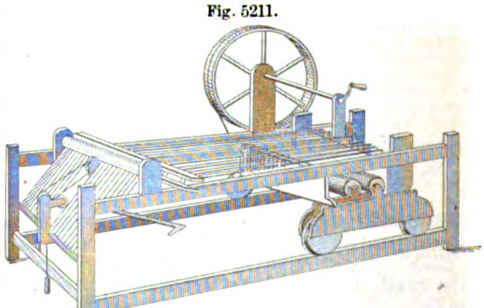
Other modes of giving the twist which makes the distinction between a *roving* or *slub* and the *sliver* from which it is produced are the *jack* and the *bobbin and fly frame* (which see). See also ROVING; DOUBLING.

Slub′bing-bil′ly. The first spinning-machine for drawing and twisting slightly the *cardings* or scribblings of wool. See SLUBBING-MACHINE.

Slub′bing-ma-chine′. A *slubbing-billy*. A machine for giving a light twist to the *cardings* of wool.

The *slubbing-billy* consists of a wooden frame, within which is a carriage called the *billy-gate*, moving upon the lower side-rails, and containing a number of spindles which are made to rotate by a series of cords passing round the pulley of each spindle and connected with a drum extending the whole breadth of the carriage. The drum is turned by a crank-handle on a shaft connected by a band with the drum.

Fig. 5211.



Slubbing-Billy.

The *cardings* are arranged upon an inclined leather apron, and pass from thence under a wooden roller called the *billy-roller*, which compresses them slightly. In advance of the roller is a movable rail, which is lifted to allow the cardings to be drawn out by the carriage, and is shut down when the portions

of the cardings beyond the clasp are to be drawn out into an elongated thread.

The machine was introduced soon after the invention by Hargreaves of the *spinning-jenny*, about 1767. The jenny was the original of the *slubbing-billy* and the *mule*; the traveling carriage carrying spindles, the interrupted paying out of the carding or roving, the elongation of the roving and spinning of the thread during the forward motion of the carriage, and the winding of the *cop* during the return motion, are common to the *slubbing-machine* and the *mule*. The points of difference between the two machines last cited and the *jenny* may be seen by comparing them with the latter. See SPINNING-JENNY.

In operation, the spindle-carriage is wheeled close up to the *billy-roller*, and the clasp is opened by means of a lever to release all the cardings. The carriage, being drawn forward a short distance from the clasp, pulls forward a corresponding length of the cardings; the clasp is then lowered, holding the cardings firmly, while the carriage, continuing to recede, stretches and twists that portion of each carding which is included between the spindles and the clasp. During the motion of the carriage, the attendant rotates the crank-shaft, and the spindles are rapidly revolved, giving the cardings the required degree of twist for this part of the process. The slubbing-machine does not make *yarn* but *slubs*, which have only a partial twist. The inclined position of the spindles prevents the cardings from unwinding upon them during the twisting part of the process, the rovings continually slipping over the points of the spindles as the latter rotate. When the requisite elongation and twist is attained, the attendant drops the *faller-wire*, which bears down the rovings from the points of the spindles and causes the slubbing to wind upon the spindles as the carriage is pushed back toward the *billy-roller*.

The *cardings* are very tender, and will not bear drawing upon the inclined apron, so the latter is caused to move upward with the cardings to an extent and at a time coincident with the paying out of the carding by the *billy-roller* at the early part of each forward motion of the spindle-carriage. New lengths are added to the ends of each carding as they are gradually fed through the roller, the junction being made by a peculiar rolling of the ends together by the fingers of the children in attendance. One carding-machine will keep a slubbing-machine of 60 spindles in work. One boy will manage 30 cardings.

The slubbing-billy is sometimes employed to spin coarse yarn, but usually leaves the *slub* about double the size that the yarn is intended to be. The farther reduction — that is, elongation and twist — is obtained in the *mule*.

Another form of *slubbing-machine* is termed a *condenser*, and requires a different preliminary treatment of the wool. The *scribbling-machine*, or first carding-machine, delivers the *fleece* or *lap* on to a wooden cylinder, round which it winds as it is taken off the *doffer* by the *comb* When the *fleece* has wound round the roller a certain number of times, a bell is rung mechanically, which gives notice for the removal of the fleece, which is done by running the finger lengthwise along the periphery of the roller, dividing the fleece, which is removed in a sheet to the second carding-machine, whose feed-cloth it just covers.

The doffing-cylinder of the second carding-machine has circumferential rings of cards around, each about ¾ inch broad, and divided by spaces of ¼ inch These rings become charged with wool, which is removed by the *comb* or doffing-knife in the form of separate slivers, one from each ring, the slivers being subsequently formed into continuous slubbings by means of the *condenser*.

The *condenser* consists of a pair of rollers supporting a traversing belt of leather, on which the slivers are carried; a third roller of leather lies transversely upon the slivers and the leather belt, having, in addition to its rotary motion, an endwise motion, which rolls the slivers into a somewhat cylindrical form, compacting them and causing the fibers to interlace. By this means the slubbings acquire sufficient strength to enable them to stand the operation of spinning. The effect is similar to rubbing the sliver between the hands.

The slubbings thus formed are wound upon a horizontal reel, as long as the width of the machine. This, when full, is removed and placed on the mule, which draws from it, the same as it would from bobbins on a creel.

Sludge. (*Metallurgy.*) The metalliferous slime from the ore-stamp. See SLIME; AMALGAMATOR; SIZING-CISTERN; SEPARATOR.

Sludge-hole. (*Steam.*) A hole in a steam-boiler at which mud or deposits are raked out.

Sludg'er. A cylinder forming a bucket for removing mud from a bored hole in rock or soil. Known also as a *sand-pump*, or *shell*. See page 2027.

Sludg'ing. (*Hydraulic Engineering.*) Stopping the crevices incident to the contraction of clay piled in embankments, by mud sufficiently fluid to run freely.

Slug. 1. (*Printing.*) A strip of metal less than type high and as long as the width of the column or page. Slugs are used to fill out a short page or between *display lines*.

2. (*Projectile.*) *a.* An extemporized leaden projectile formed by cutting bar or sheet lead into irregular masses; used in case of necessity as a substitute for balls or shot.

b. In breech-loading arms, which carry a bullet slightly larger than the bore of the barrel, the bullet, when forced to assume the sectional shape of the bore in the act of firing, is said to *slug* or to be *slugged*.

3. (*Metallurgy.*) Partially roasted ore.

4. (*Hat-making.*) A hatter's heating-iron.

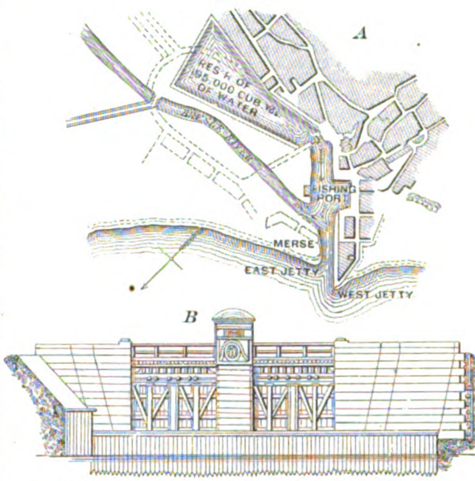
Sluice. 1. (*Hydraulic Engineering.*) A waterway provided with a valve or gate by which the flow of the water is controlled. It is used in regulating the passage of water into and out of canal-locks and in the hydraulic arrangements for sluicing harbors to deepen the channels.

The sluices of the northern French ports of Dieppe, Treport, Havre de Grace, and Cherbourg, are good examples of sluices of the latter description. The fresh water of rivers or canals is reserved by means of a barrier, or the sea-water is allowed to flow through the open sluice into a reservoir while the tide is rising; at low water the sluice is opened, and the rush of water cleans out the silt, sand, and mud which obstruct navigation.

The sluice constructed by De Cessart at Treport, France, may be taken as an example.

De Cessart improved this port in 1778, and constructed the scouring-sluice, by which the port is kept constantly cleansed.

Fig. 5212.



Treport Harbor and Elevation of Scouring-Sluice.

It has two passages for the water, each 21 feet in width, separated by a pier 8 feet thick, terminated at the sides by walls 10 feet in thickness, with wing walls and returns.

The platform fills the space between the walls, both above and below. Below the apron is a row of sheet piling, which keeps the earth of the foundation from washing away. Above these are two rows of sheet piles, which prevent the work from being undermined.

Each of the two passages is closed by two gates, 12 feet in hight; a wooden bridge, 13 feet wide, affords a passage across the sluice. The upper platform is constructed of timber, so that it can be readily repaired, without injury to the walls. The pivots and sockets on which the gates move are of cast-iron, each weighing 193 pounds. The lower rail of the gates is kept 2 inches above the level of the platform; a sill of the same hight fills this space and prevents loss of water. The gates turn in circular indents in the side walls, and the difference in the areas of their sides is about 6 inches, which suffices to open them when the tide rises.

Sluices were used from a very early period to assist in raising or lowering vessels from one level to another in canal or slack-water navigation, or in overcoming shallows or bars of rivers.

The most ancient on record is that of the canal of Pharaoh Necho, which united the Red Sea with the Nile. Diodorus Siculus (60 B. C.) states that this had sluices or gates ingeniously

contrived, which opened to afford ships a passage through and then quickly shut again. He speaks of the canal as constructed by "Necos, the son of Psammeticus," afterward partially restored by "Darius the Persian," and subsequently by "Ptolemy the Second."

Strabo mentions an *eriplus* (a gate) which Ptolemy Philadelphus constructed when he reopened the canal, and which opened an easy passage from the Red Sea to the canal. The French Survey, during their occupation of Egypt, determined that the Red Sea at Suez at high water is 32 feet 6 inches higher than the Mediterranean at Tyneh at low water.

The ancient canal was made by Sesostris, according to Aristotle, Strabo, and Pliny. It commenced about 12 miles northeast of the modern town of Belbays, the *Bubastis Agria* of the Romans, and was about 96 miles long. It appears to have been reopened by Necho, about 605 B. C., and Ptolemy Philadelphus, about 300 B. C. 60,000 men are said to have perished in the latter undertaking. It was neglected by the Cæsars, reopened by the Caliphs, and abandoned when the route by the Cape of Good Hope was discovered.

According to historians, the undertaking was several times abandoned by the fear of flooding Egypt with salt water, the Red Sea having a higher level than the Nile. The sluice or *gate* at the Red Sea end seems to have prevented the steady flow of the salt water to the sacred river. The modern canal, in connecting the salt waters of the Red Sea and the Mediterranean, has not raised the question.

Sluices are used for overcoming the different levels on the great rivers of China, but whether they use locks is not known to the writer. The Great Canal of China is 825 miles long, 200 feet broad, and deep enough for vessels of large cargo. It was commenced in the ninth century, about the time of Charlemagne. The authorities which give it a length of 2,000 miles probably include branches or the rivers which are included in the system of inland navigation. See CANAL.

The canals of the Romans and those of the Italians down to the fourteenth century were furnished with sluices, and no certain mention of canal-locks occurs previous to the time of the brothers Domenico. See CANAL-LOCK.

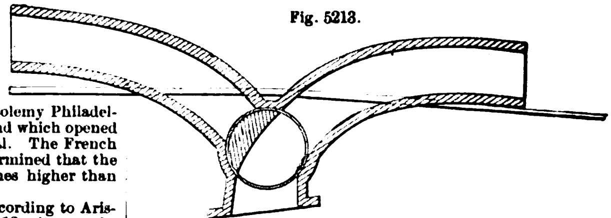
The sluice-gate of Italy is thus described by Cresy: —

"The lower beam of each gate was framed with the head and heel posts, so as to allow a space of six inches between it and the sill. From the middle beam to the top, the gates were planked over in the ordinary way; the lower part was left open or in skeleton framing, and was closed by paddles and sluices, which were moved up and down by rack and pinion. When the paddles were let down, they descended three or four inches lower than the surface of the floor on the lower side, which acted as a rebate, against which they pressed, and effectually closed the lock. They also had a bearing against the lower cross-beam of the gate, and the head and heel posts rested on square stones made fast in the sill.

To make use of these gates, it was necessary, first, to raise the paddle as high as the lower cross-beam, which permitted the water to pass through at the foot of the gate. The paddles were then elevated to the hight of the middle beam, which was placed at the ordinary level of the water, usually four or five deep upon the sill.

The gates were easily opened, as the boarded part was entirely out of the water. A serious objection to this early contrivance in aid of internal navigation is the injury that vessels might sustain at the time of passing through when one end was elevated out of the water. The sides and floor of the sluice were boarded and a foot of length was allowed for every inch of fall."

Fig. 5213.



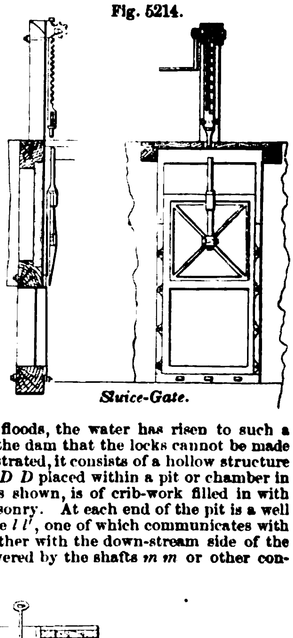
Sluice for Hydraulic Propeller.

2. (*Steam.*) The injection-valve by which the water of condensation is introduced into the condenser from the sea, river, or well.

3. A *tubulure* or pipe through which water is directed at will. In the hydraulic propeller, in which a vessel is driven by an issuing column of water, the sluice-way is controlled by a valve. In the example, a rotating sluice is placed at the point of divarication of the passages of a rotary pump to give direction to the discharge of the water, for going ahead or backing.

Sluice-gate. (*Hydraulic Engineering.*) *a.* Lock-gates of canals are provided with sluice-gates, as are also the sluice-walls in other structures where a flush is obtained by the sudden releasing of the pent-up water. The sluice-gate is a simple plate, which covers the opening, and is raised or lowered by means of a rack-bar and pinion. See FLUSHING.

Fig. 5214.



Sluice-Gate.

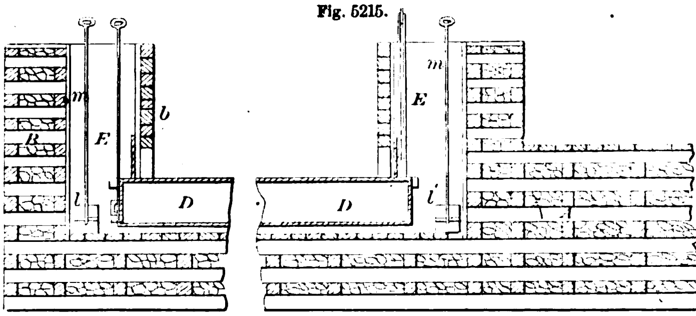
Brunot's (Fig. 5215) is more particularly designed for application to dams erected for purposes of slack-water navigation, and is intended to be available when, in floods, the water has risen to such a hight over the head of the dam that the locks cannot be made use of. In the form illustrated, it consists of a hollow structure of timber or plate-iron D D placed within a pit or chamber in the dam A B, which, as shown, is of crib-work filled in with stone, but may be of masonry. At each end of the pit is a well E E provided with a gate l l', one of which communicates with the up-stream and the other with the down-stream side of the dam, and is raised or lowered by the shafts m m or other contrivances. The gate D D is also provided with valves, which are opened or closed to admit or withdraw water as required. At ordinary stages of water, it is retained at a level with the head of the dam and assists in retaining the water behind it; but when the river has risen to a considerable hight above the dam, one or more of the valves are opened, permitting the water to flow into the gate, which sinks, leaving the sluice open so that it

A *falling-sluice* is one whose gate falls by pressure, to enlarge the waterway during floods.

Sluices are used in all systems of drainage on a large scale, where a periodical fall is obtainable, as in marshes on tide-water, where the fresh water of the drains is allowed to pass off at the lowest state of the tide.

This has been practiced from time immemorial in the low countries bordering on the mouths of the Rhine and neighboring rivers; also in the Italian systems of drainage, though the facilities there are not great, as the tides of the Mediterranean have a much smaller range of elevation.

Fig. 5215.



Sluice-Gate.

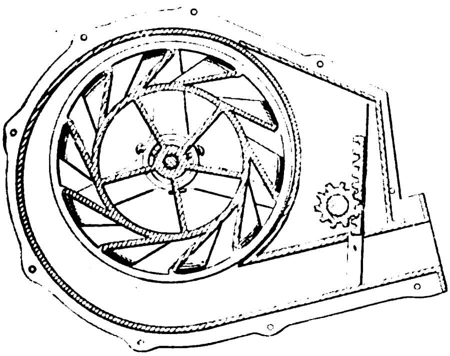
The Romney marsh, Essex, England, was obtained from the sea nearly 2,000 years back, and consists of 24,000 acres. The water is kept back by a levee 6,000 yards long, and the fresh water from the ditches passes out at the lowest state of the tide by three sluices.

For modern data on sluices, barrages, and slack-water dams, see "Report on Hydraulic Gates and Dams in the Ohio River," Ex. Doc., No. 78, 42d Cong., 2d Session.

may afford a passage for boats. When the gate $D\ D$ is to be raised, the gate l' of the down-stream passage of the well E is opened and the other gate l of the up-stream passage is closed, permitting the water to flow wholly or partially out of the pit, and the appropriate valve in the gate DD is also opened, allowing water to escape from and air to enter it, so that it will float. The valve is then closed and the action of the gates $l\ l'$ reversed, again filling the pit with water, upon which the gate $D\ D$ rises and closes the sluice as before.

b. The gate which admits water to the scroll-chute

Fig. 5216.



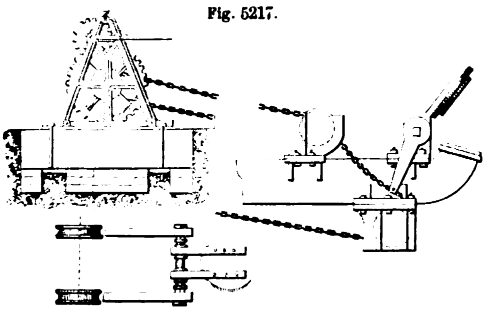
Sluice-Gate for Water-Wheels.

of a water-wheel. In the example, this is worked by rack and pinion.

Sluice-valve. The sliding door which governs the opening through a sluice-gate.

Sluice-valves at the mouth of a discharge pipe or main serve to control the exit of water from a reservoir. They are of several kinds: some are made to slide in ways to and from the seat,

Fig. 5217.

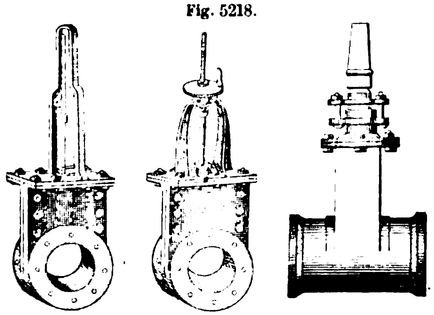


Sluice-Valve.

like those described under STOP-VALVE; and others are more nearly allied to the clack-valve, being opened by machinery against the pressure of water.

In the latter case, the valve which covers the mouth of the discharging pipe has two arms secured to an iron axle, at the extremities of which are two levers. The chain fastened to one pulley passes under a pulley, and that fastened to the other lever passes over another pulley, so that by turning a windlass either chain can be worked for the purpose of opening or closing the valve, respectively.

Fig. 5218.



Sluice-Valve.

Fig. 5218 shows three varieties of valves for gas, water, and steam pipes; the first is raised and lowered by a rack and pinion, the second by a screw, the third by a key or wrench.

Slung-shot. (*Weapon.*) A leaden ball with a strap attached.

Slur. 1. (*Knitting-machine.*) A piece of metal in a stocking-frame which travels on a *slur-bar* beneath the ends of the *jacks*, and thus depresses the *jack-sinkers* in succession, *sinking* one loop of thread between every pair of needles.

2. (*Printing.*) A blurred impression.

Slur-cock. (*Knitting-machine.*) A cam or wiper projecting from the traverse or carriage to lift the *jacks*, and through them the *jack-sinkers*.

Slush. 1. A mixture of grease and other materials used for lubrication.

2. White-lead and lime used in painting bright parts of machinery.

Slushed-up. (*Bricklaying.*) The joints and intervals between the bricks and courses filled with mortar. See GROUT.

Smack. (*Nautical.*) A one-masted vessel, resembling a sloop or a cutter, as the case may be, and used in the coasting-trade. The Leith (Scotland) smacks ran as high as 200 tons.

Small-arm. A term including muskets, rifles, carbines, and pistols. In the English service there were, until lately, seventeen varieties, issued to the cavalry, artillery, engineers, infantry, and navy. Eleven other kinds are issued for service in India. The tendency now is to reduce the variety of pieces and have a greater uniformity of bores and ammunition. See FIRE-ARM; PISTOL; RIFLE; SHOT-GUN; REVOLVER, etc.

Small-chis'el. A burin or graver used by engravers, chasers, etc.

Small Pi'ca. (*Printing.*) A size of type between *Long Primer* and *Pica.*

Long Primer, 89 ems to a foot.

Small Pica, 83 ems to a foot.

Pica, 71 ems to a foot.

Smalt. A blue coloring material prepared from cobalt ore. It is extensively used for tinting glass, painting porcelain and earthenware, fresco-painting, tingeing linen and paper, coloring paper-hangings, and other purposes.

The ore of cobalt was first known in the Saxon mines as an impurity of silver ore, and its property of imparting a blue color to glass was accidentally discovered. In its native state it is mixed with various other metallic compounds, as those of arsenic, bismuth, nickel, etc. It is prepared by stamping, washing, and roasting. The residue is mixed with potash and calcined quartz-rock, and melted in pots in a furnace resembling that of the glass-maker, forming a beautiful blue glass. The smalt thus produced is crushed, sifted, ground, washed, and sorted into fine powders of various tints of blue, constituting the smalt, azure, etc., of the color-shops. An inferior kind is termed *zaffre.*

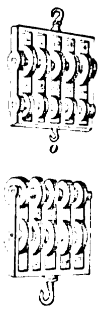
Smash'ing-ma-chine'. (*Bookbinding.*) A press made on the principle of an embossing-press, and used for compressing books.

Smear'ing. (*Pottery.*) An operation in firing pottery whereby an external luster is imparted to pottery without glazing. The saline flux of the saggars is reverberated and condensed upon the ware, or a fusible composition is so placed that the vapor reaches the ware.

Smea'ton's Block. A compound block devised by the celebrated engineer Smeaton and designed to

keep the cords parallel and prevent the displacement by tension incident to systems of blocks combined together.

Fig. 5219.



Smeaton's Block.

The course of the rope may be traced by the numbers on the sheaves.

One end of the rope is attached to the hook *o*, at the bottom of the upper block; from this point the rope is brought under the wheel marked 1, over 2, under 3, over 4, under 5, and so on, according to the order of the figures, until it is finally passed over the wheel marked 20, on which the power immediately acts. In this arrangement the blocks cannot get deranged, because the power acts directly over the weight. The weight being distributed over 20 parts of the rope, which are equally stretched, it follows that the weight is 20 times the power.

Smed'dum. (*Metallurgy.*) The smaller particles which pass through the sieve of the *hotching-tub* or *hutch* in the water treatment of ores by agitation.

Smee Bat'ter-y. (*Electro-magnetism.*) A form of single-fluid galvanic battery, invented by Alfred Smee, F.R.S., surgeon to Bank of England, in which copper mechanically roughened is the + element and silver roughened by a deposit of platinum is the − element. It was found that this roughening prevented the adherence to the plates of the bubbles of hydrogen evolved during action.

Smeir. (*Pottery.*) A semi-glaze on pottery; common salt added to an earthenware glaze.

Smelt. To fuse; as an ore, to extract the metal from extraneous substances.

Smelt'er's Fume. (*Metallurgy.*) The metallic fume resulting from the smelting of lead, the sublimation of zinc from ore, mercury from cinnabar, etc.

The fumes of some lead-smelting furnaces are 3 feet in width, 6 feet in hight, and are sometimes several thousand yards in length.

The gallery of the Allen lead-mill, Northumberland, England, has a length of 8,789 yards (nearly 5 miles), a hight of 8 feet, and a width of 6. The lead thus collected in Mr. Beaumont's mines, in the district mentioned, amounts to $50,000 annually.

Quicksilver furnaces are elaborate examples of this form of condenser. See MERCURY; ALUDEL.

Blende or black-jack is sublimed, and the fumes filtered through bags. See ZINC.

The fumes of the copper-smelting furnace are led to great distances to avoid injury to animal and vegetable life in the vicinity. Sulphur and arsenic fumes are an incident to many metallurgical operations.

Condensers, of much smaller proportions, in which the assistance of water is invoked, are in common use. See CONDENSER.

The *arsenic* and lampblack chambers are merely large buildings, with one or more apartments, in which the fumes cool and deposit

Smelt'ing. The process of obtaining metal from ore by the combined action of heat, air, and fluxes.

Smelt'ing-fur'nace. A furnace for disengaging the metal from its gangue or the non-metalliferous portions of the ore. The furnaces differ much for treating different metals. See list under METALLURGY; FURNACE.

The smelting-furnace for iron is in the form of a truncated quadrilateral pyramid about 50 or 55 feet high. The outer part is of brick or squared stone, with contrivances to obviate the danger of its cracking by the expansion that takes place when it is heated, and it is lined with two courses of fire-bricks having a layer of pounded coke between them to prevent the escape of the heat. The interior or cavity may be divided into the following parts from below upward. First, the hearth, about two feet high; its base and sides are formed of massive blocks of coarse, pebbly gritstone, as being the most infusible of all common building-stones. Upon this is erected the crucible, a four-sided cavity between 6 and 7 feet high, slightly enlarging upward, so as to be at top about 2½ feet wide. The part above, called the *boshes*, is in the shape of a funnel or inverted cone, about 8 feet high and 12 feet wide at top. On this is placed the great cavity of the furnace, of an irregular conical form, about 30 feet high, and gradually narrowing so as to be only about 3 feet in diameter at the top. From this part it enlarges into a funnel-shaped chimney, about 8 feet high, in which is cut a large square aperture, through which the charge is thrown from time to time into the furnace. About two feet above the hearth is an aperture through which the blast-pipe or tuyere is introduced. Sometimes there are two opposite tuyeres, and occasionally even three.

The character of the iron is affected by the nature of the fuel, and, by the choice of the latter, metal may be rendered more suitable for the purpose for which it is intended.

The effect in the smelting-furnace is due to the high temperature, and this is produced by the action of the oxygen of the atmosphere, which enters at the tuyere-hole, excites intense heat by combination with the carbonaceous particles of the fuel, the other constituents of the air passing out, in company with certain gases evolved, at the top of the furnace.

The air may be hot or cold, but is driven by a machine of some description. Varieties of the original forms of blowers may be found under *bellows*, but the larger kinds of blast apparatus are associated under the caption BLOWERS (which see). In a furnace working under high pressure and delivering 6,292 cubic feet per minute (estimated at atmospheric pressure), the weight of the air thrown in is calculated at 693,504 pounds, while the charge of coke, ore, and limestone in the same time amounts to 74,648 pounds.

The heat is developed, as has been said, by the combination of the oxygen of the air with the carbon of the fuel; but part of the carbon is required to reduce the magnetic oxide to the metallic state, and some carbon is also required to unite with the iron to form cast-iron, which is a compound of iron and carbon. The amount of air required will therefore be the quantity necessary to combine with the remainder of the carbon of the fuel, after deducting the amount of carbon required to reduce the oxide, and to unite with the metal.

The charge, placed on top of the furnace, descends gradually, the iron becoming gradually carbonized. As the carbon penetrates the fragments of ore, the limestone parts with its carbonic acid, which passes off The fuel loses some of its combustible ingredients. As the charge comes under the direct action of the blast, the reactions are more energetic, the fuel burns rapidly, its carbon uniting with the oxygen and with the metal, which becomes melted, while the lime unites with the earthy particles to form a fusible slag; the fused matters descend from the boshes into the crucible, the metal, by its superior gravity, taking the lower position on the hearth, from whence it is drawn off from time to time, either into ladles to form castings, or into furrows made in sand, where it is run into pigs.

The vitreous scoriæ or *slag* floats on the iron and overflows at an aperture. See SLAG; BLAST-FURNACE.

The appearance of the slag indicates the cooking condition of the furnace. Here the skill of the smelter will watch the healthy working of his furnace, detect the signs of disorder, and determine upon the appropriate remedies.

An authority gives the following indications: If the color of the slag be pale yellow, the sign is favorable. Green color indicates oxide of iron and a deficiency of lime. Streaks of blue indicate protoxide of iron, and show a deficiency of fuel or excess of blast.

Dark-colored, heavy slag shows that iron is going to waste, and suggests that the iron produced will be deficient in carbon. It indicates either a deficiency of fuel or a too rapid working of the furnace, so that the iron was imperfectly carbonized on arriving within the action of the blast.

Great economy of fuel, with a generally admitted deterioration of quality of the metal, is effected by using a blast, heated artificially. The heat attained varies from 200° to 600° Fah. This was invented by Neilson. See HOT-BLAST.

The primitive smelting-furnace by which the "iron is taken out of the earth" (Job xxviii. 2), and which the Hebrews learned to use while in Egypt, was probably like the ancient Indian furnace yet used in Asia, and thus described by Dr. Ure: —

"The furnace or *bloomary* in which the ore is smelted is from 4 to 5 feet high; it is somewhat pear-shaped, being about 5 feet wide at bottom and 1 at top. It is built entirely of clay. There is an opening in front about a foot or more in hight, which is filled with clay at the commencement, and broken down at the end of each smelting operation. The bellows are usually made of goat's skin, and the nozzles are inserted into tubes of clay which pass into the furnace.

"The furnace is filled with charcoal, and a lighted coal being introduced before the nozzles, the mass in the interior is soon kindled. As soon as this is accomplished, a small portion of the ore, previously moistened with water to prevent it from running through the charcoal, but without any flux whatever, is laid on top of the coals, and covered with charcoal to fill up the furnace. In this manner ore and fuel are supplied, and the bellows urged for three or four hours. When the process is stopped, and the temporary wall in front broken down, the bloom is removed with a pair of tongs from the bottom of the furnace."

It was said of the land of Canaan (Deuteronomy viii. 9), "a land whose stones are iron, and out of whose hills thou mayest dig brass" (copper). The hills of Palestine furnished the ore in the time of the Judges, and do to this day. It was used for making the bedstead of Og, king of Bashan (see BEDSTEAD), for the axes and sickles of the Egyptians from time immemorial, and for axes in Palestine in the times of Samson and Elisha; for chains in the time of Jeremiah; harrows in the time of Samuel and David; for mattocks, files, goads, swords, spears, shares, colters, forks, etc., previous to the time of Saul, say about 1100 B. C., and no doubt long before.

The Israelites worked in the iron-furnaces of Egypt during their captivity. The rigidity and strength of iron afford a basis for several metaphors in that most ancient and wonderful poem, the Book of Job.

The iron-smelting furnaces of Africa are thus described by Dr. Livingston: —

"At every third or fourth village (in the regions near Lake Nyssa) we saw a kiln-looking structure, about 6 feet high and 2½ feet in diameter. It is a clay, fire-hardened furnace for smelting iron. No flux is used, whether the specular-iron, the yellow hematite, or magnetic iron ore be used, and yet capital metal is produced. Native manufactured iron is so good that the natives declare English iron 'rotten' in comparison, and specimens of African hoes were pronounced at Birmingham nearly equal to the best Swedish iron."

Dr. Barth makes a similar statement.

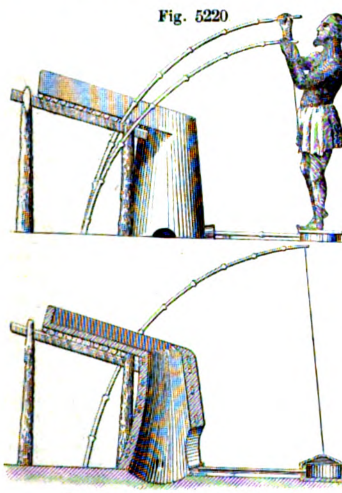
The articles produced by these peoples are hammers, tongs, hoes, adzes, fish-hooks, needles, and spear-heads. The *assagais* of the Caffres are made of iron similarly procured, and of excellent quality. The *wootz* of India is still produced in the manner partially described by Aristotle when speaking of India, and by Diodorus Siculus, referring to the iron ores of the island of Ethalia.

The Hottentots, though so far below the average of what may be classed as savages, have pottery, iron manufactures, sheep, and oxen.

Their iron-furnace is a hole in a raised ground, large enough to contain a good quantity of iron stones, which are plentiful on the surface in some parts of their country. About 18 inches from the upper hole they make a smaller one, connecting with the former by a narrow channel. A hot fire is made in the upper hole, sufficiently long to heat the earth thoroughly, and it is then charged with fuel and iron. Fuel is added, and the fire urged until the metal runs into the receiver. When it is cool it is broken into pieces, heated, and hammered out with stones. It is almost exclusively used for making weapons.

Fig. 5220 represents a blast-furnace of the Kols, a tribe of iron-smelters in Lower Bengal and Orissa. The men are nomads,

Fig. 5220



Kol Smelting-Furnace, Hindostan.

going from place to place, as the abundance of ore and wood may prompt them. The charcoal in the furnace being well ignited, ore is fed in alternately with charcoal, the fuel resting on the inclined tray, so as to be readily raked in. As the metal sinks to the bottom, slag runs off at an aperture above the basin, which is occupied by a viscid mass of iron. The blowers are two boxes with skin covers, which are alternately depressed by the feet and raised by the spring-poles. Each skin cover has a hole in the middle, which is stopped by the heel as the weight of the person is thrown upon it, and is left open by withdrawal of the foot as the cover is raised.

Variously modified in detail and increased in size, these simple furnaces are to be found in several parts of Europe, the Catalan and Swedish furnaces resembling in all probability those of the Chalybes, so famous in the time of Marathon (490 B. C.), and those of the *fabrica* or military forge established in England by Hadrian (A. D. 120) at Bath, in the vicinity of iron ore and wood. The brave islanders met their Roman invaders with scythes, swords, and spears of iron, and the export of that metal from thence shortly afterward is mentioned by Strabo.

During the Roman occupation of England some of the richest beds of iron ore were worked, and the *débris* and cinders yet exist to testify to two facts, — one, that the amount of material treated was immense; the other, that the plans adopted were wasteful, as it has since been found profitable to work the cinders over again.

During the Saxon occupation the furnaces were still in blast, especially in Gloucestershire.

The direct method of obtaining wrought-iron from the ore prevailed until the commencement of the fifteenth century, and then gradually gave way to a less direct process, but one more convenient in the handling of large quantities. Furnaces, operating by the aid of a strong blast, to *melt* the iron and obtain *cast-iron*, which is carbureted in the process, were in use in the neighborhood of the Rhine about 1500. A second process in a *forge* hearth was used to eliminate the carbon and other impurities, and the result was *wrought-iron*.

It took several centuries to accomplish this with wood, and several other centuries to devise means for substituting pit-coal for charcoal.

In the reign of Elizabeth blast-furnaces were of sufficient size to produce from two to three tons of pig-iron per day by the use of charcoal. In the small works the iron was made malleable before being withdrawn from the blast-furnace, and in larger works was treated by the refinery furnace.

Wood becoming scarce, and a number of furnaces having gone out of blast, in 1612 Simon Sturtevant was granted a patent in England for 31 years for the use of pit-coal in smelting iron. Failing in his proposed plans, he rendered up his patent in the following year. Successive persons applied for a patent for the same, the government continuing desirous of encouraging the development of home resources. Dudley, in 1619, succeeded in producing three tons of iron per week in a small blast-furnace by the use of coke from pit-coal. The parties who yet possessed plenty of wood, and with whom the production of iron was fast becoming a monopoly, urged the charcoal-burners to destroy the works of Dudley, which was done. Dudley's patent was granted for 31 years, which would bring it to 1650, the time of the Protectorate, when England had a ruler fit to succeed Queen Bess. The celebrated statute of King James, limiting the duration of patents to 14 years, was passed in 1624. Dudley's petition for an extension was refused.

Iron of poor quality continued to be made in districts where wood was scarce, and of good quality from charcoal in places where forests yet remained. The demand for iron continuing to grow, — a natural effect of advancing civilization, — iron was imported from Sweden and Russia in large quantities and of excellent quality. The forests of these countries gave them a natural advantage over England, whose forests had by this time become thinned out, so that the use of wood for iron smelting had been forbidden by act of Parliament in 1581 within 22 miles of the metropolis, or 14 miles of the Thames, and eventually was prohibited altogether.

The art of making iron with pit-coal and of casting articles of iron was revived by Abraham Darby, of Colebrookdale, about 1713, and was perseveringly followed, although it was but little noised abroad. In the "Philosophical Transactions" for 1747 it is referred to as a curiosity. See CASTING, p. 449.

The extension of the iron manufacture dates from the introduction of the steam-engine, which increased the power of the blast; and the blowing engines, driven by manual, horse, or ox power, were henceforth operated by steam-engines. The dimension of the blast apparatus was increased from time to time, and about 1760 coke was commonly used in smelting. In 1760 Smeaton erected at the Carron Works the first large blowing cylinders, and shortly afterward Boulton and Watt supplied the steam-engines by which the blowers were driven. Neilson, of Glasgow, introduced the hot blast in 1828. Aubulos, in France, in 1811, and Budd, in England, in 1845, heated the blast by the escaping hot gases of the blast-furnace. In the smelting of iron four tons weight of gaseous products are thrown off into the air for each ton of iron produced. See under IRON; MALLEABLE IRON; and other titles, for which see list under METALLURGY.

As a means of estimating by comparison the value of the hot blast, some facts may be mentioned. Mushet states that at the Clyde Iron Works, before the introduction of the hot blast, the quantity of materials necessary for the production of one ton of pig-iron was, —

Calcined ore	1¾ tons
Coke	3 tons
Limestone	½ ton.

In 1831, when the system was coming into use, the blast being *warm*, —

Calcined ore	2 tons
Coke	2 tons
Limestone	½ ton.

In 1839, with a hot blast, —

Calcined ore	1¾ tons
Coke	1¾ tons
Limestone	½ ton

the saving in fuel being nearly one half.

In addition may be mentioned the fact that anthracite coal and black band ore are intractable under the cold blast, but the former yields an intense heat, and the latter a rich percentage of good iron with the hot blast.

The Calder Works, in 1831, demonstrated the needlessness of coking when the hot blast is employed.

Experiments in smelting with anthracite coal were tried at Mauch Chunk in 1820, in France in 1827, and in Wales successfully by the aid of Neilson's hot-blast ovens in 1837. The experiment at Mauch Chunk was repeated, with the addition of the hot blast, in 1838–39, and succeeded in producing about two tons per day. The Pioneer furnace at Pottsville was blown in July, 1839.

The first iron-works in America were established near Jamestown, Virginia, in 1619. In 1622, however, the works were destroyed, and the workmen, with their families, massacred by the Indians. The next attempt was at Lynn, Massachusetts, on the banks of the Saugus, in 1648. The ore used was the bog ore, still plentiful in that locality. At these works Joseph Jenks, a native of Hammersmith, England, in 1652, by order of the Province of Massachusetts Bay, coined silver shillings, sixpences, and threepences, known as the *pine-tree coinage*, from the device of a pine-tree on one side.

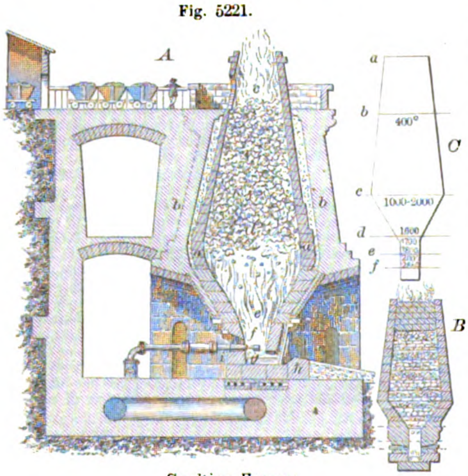
Early in the eighteenth century, a smelting-furnace was erected in Virginia by Sir Alexander Spottswood, governor of Virginia, who lived at the Temple Farm, near Yorktown, Va. He had been wounded at Blenheim, where he served with Marlborough. He was the first to cross the Blue Ridge and see the Shenandoah Valley. He was appointed commander of the expedition to Carthagena, but died at Annapolis, Md., June, 1740, as the troops were about to embark. He was buried in the mausoleum from which the Temple Farm derived its name. In this expedition the elder brother of George Washington served, and on his return named his estate on the Potomac "Mount Vernon," after the English admiral.

The blast-furnace for reducing iron from its ores is shown at Fig. 5221, *A*.

It consists of an interior lining of fire-bricks *a a*, forming a doubly conical chamber, surrounded by a packing of broken scoriæ or refractory sand, and incased within a construction of masonry *b b*, from the upper part of which the charge of fuel and ore is delivered through a suitable opening into the furnace.

The portion from *c* to *d* is termed the *shaft*; *d* to *e*, the *boshes*; the widest part being the *belly* or upper part of the boshes; the narrow part *f* the throat, below which is the crucible or hearth *g*, which receives the molten metal; the lower part of this is prolonged toward the front, forming the breast-pan, which is closed by the dam-stone *h*, between which and the side of the furnace wall is a slit, called the tap-hole, closed by fire-clay, which is removed to withdraw the molten metal. The dam-stone is protected by an iron plate. The top of the open side of the hearth is formed by a large slab of stone, termed the *tymp*, supported by a massive piece of iron, termed the *tymp-iron*. *i* is one of the tuyeres, usually two in number, through which compressed air is forced, to assist combustion and promote fusion of the metal.

Fig. 5221.



Smelting-Furnace.

The furnace is charged first with fuel, and as this burns down alternate layers of fuel and of mixed ore and limestone or other flux, according to the nature of the ore employed, are added (*B*).

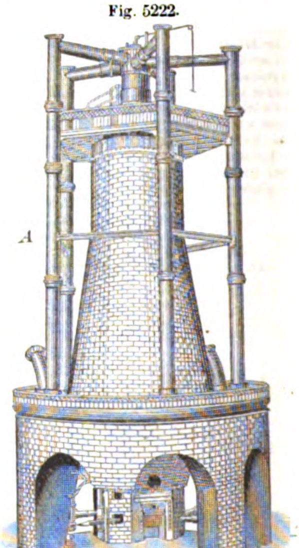
The iron collects on the hearth, while the slag produced by the combination of the flux with the foreign matters in the ore floats on top and is drawn off over the dam-stone. As the hearth becomes filled with metal, usually about twice in 24 hours, the tap-hole is opened and the metal allowed to flow.

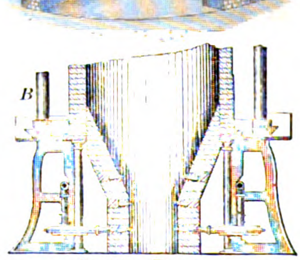
The interior of the furnace may be divided into five zones: the first heating zone *a b* (Fig. 5221, *C*); the reduction zone *b c*; the carburation zone *c d*; the melting zone *d e*; the combustion zone *e f*. In the first, the materials become thoroughly dried and are brought to a low red heat; in the second, the ore is reduced to a protoxide, and finally to metallic iron, by the various gases, carbonic oxide, carbureted hydrogen, and hydrocyanic-acid gas or vapors of cyanide of potassium; in a certain part of this zone the iron is present in a malleable state. In the carburation zone the metal becomes combined with carbon, producing a steely and caky iron, which, on falling into the lower or melting zone *d e*, becomes fully charged with carbon, by which it is brought into the condition of pig-iron.

The figures indicate the temperatures at the respective parts of the furnace.

Büttgenbach's blast-furnace is so arranged that the base is independent of the stack, which is a mere shell of fire-bricks, about equal in thickness to the lining of the ordinary blast-furnace. The base is formed either of brickwork with open arches (*A*) or of cast-iron standards (*B*). In the first case the shaft rests on a crown-ring above the tops of the arches, and in the latter upon a cast-iron ring-plate supported by the standards. The boshes join the stack just above the base-ring, and both are hooped at intervals; they and the tuyeres are protected by water-boxes. The gases are led off by a central tube, and through lateral openings, which communicate with the hollow columns, which serve as downtakes, and also support the gallery.

Fig. 5222.





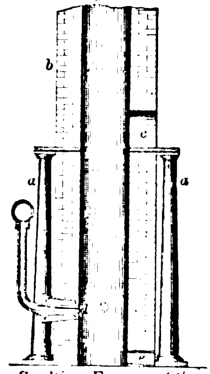
Smelting-Furnace.

Fig. 5223 is a vertical section of the smelting-furnace commonly used in the Pacific States.

Four cast-iron columns, from 8 to 11 feet high, support a square cast-iron plate *d* with a circular hole about 4 feet in diameter. On this plate is built the stack *b* of the furnace, with an opening *c* through which the furnace is charged. Under the plate and inside the columns is built the cylindrical shaft of the furnace, filling the space from the plate to the ground. *d* is a tuyere, and *e* the stirring and discharging hole.

The smelting-furnace of Shropshire, England, is a stone and

Fig. 5223.

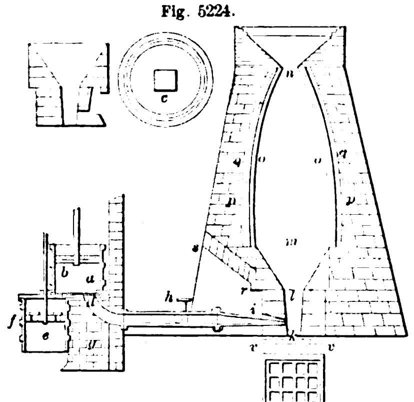


Smelting-Furnace of the Pacific States.

brick structure of a truncated conical form, 55 feet high, and 38 wide at bottom. Its cost, there, is about £1,800; and it requires in its construction 160,000 bricks, 3,900 fire-bricks, and 825 bosh-bricks. Its production is about 60 tons of iron per week. The furnaces are built larger and smaller than the size mentioned Including the coal of calcination, it is estimated that $3\frac{1}{4}$ tons of coal are required to obtain a ton of cast-iron. The proportions of the materials dumped into the furnace are $14\frac{1}{2}$ tons of coke, 16 of roasted ore, $6\frac{3}{4}$ tons of limestone, every 24 hours, producing 7 tons of pig-iron every 12 hours. Advantage is taken of a side-hill to make a convenient access for charging and delivering.

In the illustration, *a* represents the regulating-cylinder, 8 feet in diameter and hight; *b*, the floating piston, loaded with weights, proportionate to the power of the machine; *c*, a valve 26 inches long, 11 inches wide, by which the air is passed from the pumping-cylinder into the regulator; *d*, the aperture at which the blast is forced into the pipe leading to the tuyere. The pipe is 18 inches in diameter; the wider this can be made, the less is the friction and the more powerful the blast; *e* is the blowing or pumping cylinder, 9 feet high, and 6 feet in diameter, the piston within it having a stroke of from 5 to 7 feet; *f*, the blowing piston, with its valve or valves, of which there are sometimes several distributed over the surface of the piston, the area of each being proportioned to the number; *g* is a pier of stone or masonry supporting the regulating-cylinder, to which is attached the flange and blowing-cylinder; *h* is the safety-valve or cock, by the simple turning of which the blast may be admitted to or shut off from the furnace, passing to a collateral tube on the opposite side; *i*, the tuyere, by which the blast enters the furnace; the end of the taper pipe which approaches the tuyere receives small pipes of various diameters, from 2 to 3 inches, called nose-pipes; these are applied at pleasure, as the strength and velocity of the blast

Fig. 5224.



Shropshire Smelting-Furnace.

may require. *k*, the bottom of the hearth, 2 feet square; *l*, the top of the hearth, 2 feet 6 inches square; *k l*, the hight of the hearth, 6 feet 6 inches; *l* is also at the bottom of the boshes, and where they terminate is of the same size as the top of the hearth, only the former is round and the latter square. *m*, the top of the boshes, 12 feet diameter and 8 feet perpendicular hight. *n*, the top of the furnace, at which the materials are charged, commonly 3 feet diameter; *m n*, the internal cavity of the furnace from the top of the boshes upward, 30 feet high; *n k*, total hight of the internal parts of the furnace, $44\frac{1}{2}$ feet. *o o*, the lining; this is done in the nicest manner, with fire-bricks made on purpose, 13 inches long and 3 inches thick. *p p*, a vacancy round the outside of the first lining, 3 inches broad, and filled with coal-dust; this space is allowed for the expansion which might take place in consequence of the swelling of the materials by heat when descending to the bottom of the furnace. *q q*, the second lining, similar to the first. *r*, cast-iron lintel on which the bottom of the arch is supported. *r s*, the rise of the arch; the arch on the outside is 14 feet high and 18 feet wide. *v v* are the extremes of the hearth, 10 feet square; this and the bosh-stones are always made from a coarse gritted freestone, whose fracture presents large rounded grains of quartz, connected by a cement less pure.

The description by an iron-master, as given by J R. Chapin, gives a sensible idea of the process: —

"You must know that there are about 140 tons of material in the furnace, in the proportion of 60 to 75 tons of ore, 60 tons of coal, and 15 to 20 tons of limestone, fed into the furnace at the opening above The furnace is 40 feet square at bottom, and 40 feet high, with a hollow space or "flask" in the center, lined with fire-brick, and about 14 feet in diameter. The material dumped into the furnace becomes melted, and the iron, being the heaviest, sinks to the bottom, while the flux, like oil upon water, floats upon the surface, and, having an affinity for the dross of the coal and iron, it grasps and holds it separately from the metal, until it is drawn off in what is called *slag*. This is done once every hour. The gases evolved pass out at the chimney. The trouble is, the iron also has an affinity for the dross, and does, and will, retain some of it, notwithstanding all we can do.

"The floor of the building is of fine sand, divided into two parts by a track, on either side of which gutters, or *runners*, are formed leading from the mouth of the furnace. At equal distances are 8 branch gutters, or *sows*, as they are technically called, which conduct the molten ore to feed the *pigs* in the *bed*. All these are nicely formed by each set of hands after the previous cast has been cooled and removed." See BLAST-FURNACE.

"You see, there are 26 *pigs* in a *bed*, and 4 *pigs* in the *sow*; that is, they break the *sow* into 4 pieces, each the size of a *pig*. There are 16 beds, and consequently there are 480 *pigs*, or about 11 tons in each cast. At each of the branch gutters, or *sows*, a man is stationed with a spade, with which he prevents the metal flowing into his bed until the bed below him is filled, when he suddenly transplaces it, and, cutting off the flow downward, turns it into his own bed. The next man does the same in succession, and when all the beds on one side of the track are filled, the flow is turned in the same manner into the other *runner*, and the process is repeated until all are filled, when the opening in the flask is closed by clay prepared for that purpose. New supplies of coal, ore, and limestone are dumped in above, and the operation of smelting goes on for the next 12 hours."

The pig-iron is used either for casting, or for conversion into wrought-iron by puddling, etc. See CASTING; PUDDLING.

Howell's furnace for making malleable iron direct from the ore with stone coal, patented in the United States about 1831, was thus described by the inventor: "This furnace combines within itself the advantages of a close furnace and an open fire. In the upper or close portion, being all that above the hearth, with anthracite coal, excited by a proper blast, a degree of heat is generated much greater than can possibly be obtained in the ordinary fire with charcoal; while the lower portion, opening into the hearth and permitting the free action of the blast upon the burthen, performs all the offices of the open or forge fire. The ore, descending to the region of the tuyeres, becomes perfectly fused, and, passing below the influence of the blast, a part is driven out at the open front. The burthen in the furnace being temporarily supported by bars, the masses are gathered into a *loup*, which is removed by tongs and taken to the forge-hammer."

Smetz-glass. This is formed by fusing lengths of colored glass into each other, in layers either level or contorted, so the section shall resemble carnelian, agate, onyx, etc.

Smid'dum-tails. (*Mining.*) The slimy mud deposited in ore-washing.

Smift. (*Mining.*) A match of paper saturated with niter or other combustible substance, for igniting a charge of powder. A *fuse*.

Paper rubbed over with gunpowder and grease is also used by miners. See SLOW-MATCH.

Smit'ing-line. (*Nautical.*) A rope by which a yarn-stoppered sail is loosened without sending the men aloft.

Smock-mill. A form of windmill in which a cap rotates on a vertical axis to present the sails toward the wind. The term is used in contradistinction to *post-mill*, in which the whole mill rotates for a similar purpose.

Smoke-arch. (*Steam-engine.*) The smoke-box of a locomotive.

Smoke-ball. (*Ordnance.*) A paper shell filled with a composition which, when ignited, emits volumes of smoke. It is thrown into military mines to suffocate working parties, or into forts to cover an advance. It has also been used as a signal.

Smoke-bell. A glass bell suspended over a

gas-light, to intercept the smoke and prevent its blackening the ceiling immediately over the jet.

Smoke-black. Lampblack obtained by deposit of smoke from burning resinous material.

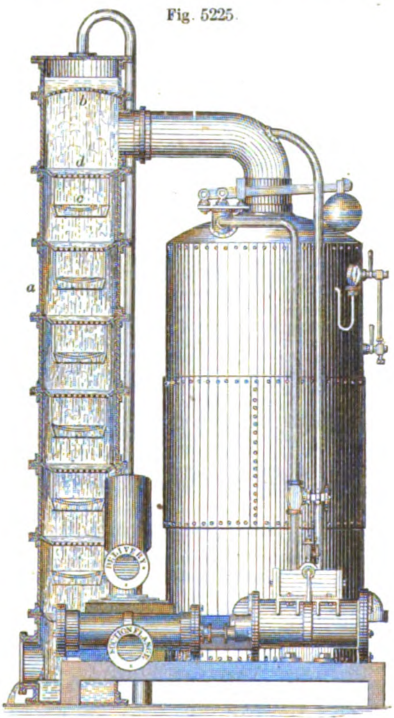
Smoke-board. A board placed against a fire-place to keep smoke from issuing into a room.

Smoke-box. (*Steam.*) *a.* A chamber in which the smoke and heated gases of the flues are collected, and from which they pass to the chimney, funnel, or stack. Some forms of reverting-flue boilers have smoke-boxes at each end.

b. In locomotives, the end of the boiler on which the chimney is placed. It receives the draft from the tubes. Locomotives with *inside cylinders* have them placed in this box, which keeps them and the steam-pipes at a high temperature.

Smoke-con-dens'er. An apparatus for precipitating the soot and smoke emanating from furnaces underground or in other confined situations. The chimney of the furnace is led into the upper part of the precipitator *a*, where it encounters a

Fig. 5225.



Smoke-Condenser.

stream of water delivered by a pump into the head of the apparatus and falling through a perforated diaphragm *b*, termed the *strom* or *strum*. The shower of water falls successively through a series of cups *c* and saucers *d*, and after having eliminated the fine solid particles from the smoke, is discharged through a pipe at the bottom. Where the water supply is large the cups and saucers may be dispensed with.

Smoke-con-sum'ing Fur'nace. Smoke has been defined as the visible effluvium or sensible exhalation of anything burning. So far as our subject is concerned, it may be considered as particles of finely divided carbon or pellicles of carbon containing inflammable gas. The object of the devices to be cited is to so apply the fuel that the escaping combustible matters shall be exposed to incandescent fuel and a due supply of vital air, which conjunction of agents will consume the combustible gases and the particles of carbon suspended therein.

In 1819, the British House of Commons appointed a commission to "enquire how far it might be practicable to compel persons using steam-engines and furnaces to erect them in a manner less prejudicial to public health and comfort, and report their observations thereupon to this House"

A large number of practical and scientific men were examined, and, the commission becoming satisfied that "the reduction of smoke from furnaces might be practically accomplished," a bill was brought forward and passed which made the avoidable production of smoke from furnace-chimneys an indictable and finable offense.

Complaints against the smoke nuisance are of very old date. Great prejudice was felt in former times in England against the burning of coal, known then as sea-coal, because it was brought from the Tyne to the Thames by sea. It was supposed to be injurious to trade, health, the complexion, and a whole catalogue of evils was feared from its use. In 1306, the king of England issued a proclamation against its use, and a commission was issued for the purpose of ascertaining who burned sea-coal within the city and its neighborhood, and to punish them by fine for the first offense and by the demolition of their furnaces if they persisted; but even these severe proceedings failed to put down the nuisance. A law was therefore passed, making the burning of sea-coal within the city a capital offense, and permitting its use only in the forges in the neighborhood. In the reign of the first Edward a man was tried, convicted, and executed for burning sea-coal in London.

"Much has been written on this branch of the subject [consuming smoke]. The principles concerned are extremely simple and easily applied.

"The volume of air supplied must be neither greatly in excess nor greatly deficient of that necessary for perfect combustion. If it be seriously deficient, the fuel, if bituminous, is partly only distilled or sublimed into black smoke and tarry soot, the adherence of which to the boiler surfaces becomes a cause of farther loss of effect.

"If the fuel be carbonaceous only, as coke, anthracite, etc., its gases are only oxidized to the state of carbonic oxide in part; and if the fuel be wood or peat, the last result occurs with the distillation of various tarry and acid products (pyroligneous acid), highly destructive to iron boilers.

"If the volume of air be greatly in excess, the heat of the furnace is reduced, and may be so to an extent to cause even imperfect combustion, and a great volume (or weight) of air is uselessly heated and discharged by the chimney.

"Non-bituminous fuel is more easily burned perfectly than bituminous; with either, but especially with the latter, if combustion is to be practically perfect, there must be a sufficient draft to carry the air-current steadily through the fuel. The layer of this upon the dead-plate and grate should never exceed 10 to 15 inches, and is best not to reach 6 or 7; but thin firing requires very careful stoking, or bare patches of grate are exposed, occasioning much loss. With coke or anthracite, and especially with a blast, a much greater depth of fuel may be practicable.

"The air is best admitted partly beneath and through the fuel, and partly in adjustable volumes, at or just behind the bridge, where it should be so arranged that the air and combustible gases shall mingle as completely as possible. This is the plan so much and so justly insisted on by Mr. C. W. Williams, Mr. Prideaux, and several others. The air admitted should be heated; and this is best of all done by the use of Mr. C. Siemens' regenerator, applied to the flues of the boiler between the latter and the chimney-stack. If the air be cold, the combustible gases are chilled more or less, and below a red heat these cannot burn perfectly or without the production of smoke. The area of air aperture at the bridge is fixed by Mr. Williams at 1 square foot for every 36 square feet of grate, when the latter burns 25 pounds of coal per foot per hour, and in like proportion for larger consumption. The maximum of economy will, in perhaps all boilers, be effected by the regenerative principle; and in this case the air passed into the flues above the fuel or at the bridge may be admitted at even 800° or 900° Fah.

"When the proportioning and arrangements of the furnace-grate and draft are such as to insure the conditions for complete combustion, the next great point to be attended to is, that the rate of passage through the flues, or past the heat-receptive surfaces of the boiler, must be such that the combustion of gases shall have been perfected before they have been robbed of so much heat by the boiler as to fall in temperature below that for complete oxidation; if not, smoke, soot, or tarry products may be still formed in the remoter ends of the flues.

"Where the regenerative system cannot be applied to the air-supply, Mr. Fairbairn's double furnace cylindrical boiler, for alternate firing, is the next best arrangement. It is one that practically works well with the ordinary amount of stoker's attention, which alone can be reckoned on." — ARMSTRONG.

One principal difficulty has arisen from the usual practice of placing the coals on top of the incandescent fuel, so that as the smoke is evolved it has free passage to escape by means of the chimney. This is the simplest way of feeding a fire, but is evidently wasteful, unless secondary means be employed to consume the matters thus escaping.

To obviate this, and cause the smoke to pass over a mass of burning fuel, various contrivances have been invented for introducing the fresh fuel beneath that which is already burning: among these may be mentioned Cutler's; and Dr. Arnott's, which is an improvement upon it. These and others are adapted for open grates. See GRATE, SMOKE-CONSUMING; BASE-BURNING STOVE.

Watt, in his specification of 1785, claims "constructing furnaces so that the smoke or flame of the fresh fuel is caused to pass, together with a current of fresh air, through, over, or among fuel which has already ceased to smoke, or which has already been converted into charcoal, coke, or cinders, and which is intensely hot." Several ways of effecting this are described by him. The introduction of fresh air, to consume the carbonaceous particles which have escaped the action of the air originally admitted to the furnace, is a very important element in producing a successful result, and appears to have been original with Watt. It has been introduced into most, if not all, subsequent devices of value.

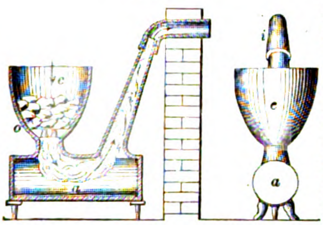
Among the plans suggested and practiced for securing the perfect combustion of the fuel and its resulting valuable gases, may be cited: —

1. Introducing the fuel into the fire in such manner that the smoke and gases evolved pass through a bed of red-hot matter.

To this class belong: —

a. The *Athanor* or constant furnace of the alchemists, used for keeping up a constant heat for many consecutive days, in their patient and laborious attempts to transmute base metals into gold, or produce the elixir of life. Alongside the fireplace was a hollow containing charcoal, and closed above by a tight lid. As the fire consumed the fuel, the charcoal descended and replenished it.

Fig. 5226.



Delasme's Smoke-Consuming Furnace.

b. Delasme's base-burning furnace, exhibited by him at St. Germain's, in 1685. It was in the form of an inverted siphon: the shorter leg *c* contained a grate *o*, and served as the fire-chamber, the longer leg *i* constituting the chimney; the smoke was thus caused to pass through the incandescent fuel, and more or less perfectly burned. The fire was kindled at the top, and the chimney *i* was heated by a lamp to originate the draft.

c. Watt's base-burning furnace, in which a body of coal is supplied in a hopper, the coal gradually falling into the fire as the substance of the lower layer is consumed. The coal-chamber may be covered in by a tight lid, so as to prevent the draft of hot air through it; or the inlet draft of air may be conducted through it. The former is perhaps the preferable mode, and the coal should be discharged through a throat of such capacity as, on the one hand, not to choke, and on the other, not to encourage, the access of fire to the contents of the supply-chamber.

Fig. 5227.

Watt's Base-burning Furnace.

In its character as a smoke-consuming furnace, it will be noticed that the fresh coal is constantly in contact with the incandescent fuel, and that all the gases evolved by the combustion are obliged to pass *through* a body of hot coals, whereby the hydrogen and carbon which constitute the valuable portion of the smoke are consumed.

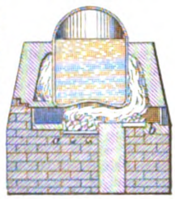
This feature is to be found in some stoves in which a body of coal is brought into contact with the fuel in such a manner that the volatile products of the fresh coal are compelled to pass *through* the incandescent mass of fuel.

d. Stoves of the base-burner class, in which the fuel is introduced beneath the fire. See STOVE, BASE-BURNER; MAGAZINE.

e. A furnace in which the escaping smoke from one fire is burnt at a second fire; also found in Watt's patent, 1785.

This is thus described in the words of the inventor: "I place the fresh fuel on a grate as usual, as at *a*, and beyond that grate, at or near the place where the flame passes into the flues or chimneys, I place another small grate *b*, on which I maintain a fire of charcoal, coke, or coals, which have been previously burned, until they have ceased to smoke, which, by giving intense heat and admitting some fresh air, consumes the smoke of the former fire."

Fig. 5228.



Watt's Double-Fire Furnace.

A modification of the Watt furnace, by a Mr. Thompson, patent 1796, had an extension of the grate bars and arched bridge, about ⅔ the distance from the front end. Beneath this bridge the volatile products of the first part of the furnace were carried, and deflected upon a mass of incandescent fuel, which occupied the rear portion of the furnace, where they were met by a current of air admitted back of the bridge. This backward portion was kept supplied with red-hot coals from the former fire, or by coke or charcoal separately introduced.

Gregson's patent, 1815 (also English), depended upon the exposure of the volatile and inflammable results of combustion, to intense heat at an aperture at the back of the fire and passing through the fire-bridge.

Losh's double-fireplace furnace, 1815, is another example of this class.

This furnace has two fires, which are alternately replenished with fuel. The fireplaces are connected, and either is thrown in connection with the chimney by means of suitable flues and dampers. The fireplace which has just received coal pours its smoke and gases into the mass of red-hot coals of the other fire, from whence the volatile matters, deprived of their inflammable gases and carbon, pass to the chimney. When the time comes to replenish the fire, the one which has acted as the secondary furnace receives the coal and delivers the smoke under the arch of the division wall to the other fire, which is connected to the chimney, by change of dampers.

The City Flour Mills, Upper Thames Street, London, are fitted with boilers consuming their own smoke, generating steam for an engine of 220 nominal horse-power. The boilers are 7 in number, and the engine is on the marine principle. The engine was formerly one of the stationary engines on the Blackwall Railway, when the carriages were drawn by a rope.

The furnaces are arranged in a row, with communicating flues guarded by dampers. When one fire has received fresh coals, its immediate connection with the chimney is closed, and the smoke is discharged into the adjoining furnace, whose fire is burning red.

2. The plan of admitting a second body of air to inflame the unconsumed combustible matters which pass away from the fire.

John and James Robertson, of Glasgow, patented a furnace in 1801, in which, by means of a pipe, air was admitted directly into the body of the fuel while burning, — the first practically successful contrivance of the kind.

In other cases, the air is admitted at or near the fire-bridge or in a chamber behind the fire-bridge.

Evett's reverberatory furnace (English patent, 1812) has a *conductor* which introduces a body of air through the bridge-wall, and ejects it upon the eddying volumes of smoke and gas which occupy the dome of the metal-chamber The size of the aperture in the air-tube was regulated by a valve. This is, perhaps, an advance upon Watt's patent of 1785, in which the accessory body of air passes through the grate-bars of a supplementary fire, which assists in the combustion of the smoke.

Chapman's furnace (1824) had hollow grate-bars, forming a series of parallel tubes opening into two boxes, one in front and the other behind the grate. The rear one connected with a hollow fire-bridge, which discharged heated air in jets into the volume of smoke passing over the bridge, thereby causing the heated gases to ignite.

C. Wye Williams' furnace depends for its action on the thorough intermingling of the gas evolved by fuel with atmospheric air before the temperature of the carbon contained in the gas, then in the state of flame, be reduced below that necessary for its ignition, — about 800°, according to Sir Humphry Davy. This is effected by admitting the proper proportion of air through several hundred half-inch orifices in and above the door-box. According to Mr. Williams, it is immaterial in what part of the furnace the air is introduced, provided that the above condition be attended to. In the experimental furnace at the Newcastle trial, the area of the openings for the admission of air was equal to four inches square for each square foot of grate-bars.

This received the prize of £500 offered by the Colliers' Association of Newcastle for the best furnace of the kind.

3. The *dead-plate* system. Also described in the specification of Watt's smoke-consuming furnace, 1785.

It had a grate with a slight descent to the rear, to enable the fuel to be pushed back from time to time, to give room for fresh coal. The fresh supply is laid on a plate called the *dead-plate*, at the front part of the grate. The fuel being *coked* by the heat, the gases and particles of carbon which form smoke are caused to pass over the incandescent fuel, and are thereby consumed.

The plan, to be successful, requires frequent feeding of the

furnace, and necessitates the opening of the furnace doors. To avoid this, self-feeders have been used, being hoppers by which the coal is introduced from time to time or continuously in small quantity.

Stanley's feed-apparatus for furnaces consists of a hopper at the front upper part of the furnace, containing a supply of small coals equal to a couple of hours' consumption. Through an aperture at the lower end of the hopper the coal drops between two grooved rollers, which crush it and allow it to fall upon the *dead-plate*, whence it is blown by air from a revolving fanner, which wafts it upon the burning fuel on the grate.

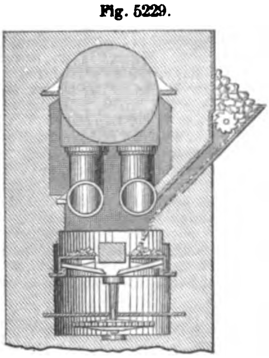
Other feed-apparatus consists in a hopper similarly situated, and having a counterpoised valve at bottom, which opens to allow the coal to fall upon the fire. Another feed will be described in connection with the *revolving grate.*

A feed-apparatus adapted to furnaces in which the fuel is burnt under pressure is illustrated in AIR-ENGINES, Bennett's patent, 1838.

4. The *revolving-grate furnace* was introduced in England by Steel, about 1818, and afterward improved by Brunton and Murray.

The fireplace is of circular form, and the grate is made to revolve on an upright axis by means of a cog-wheel on its lower extremity. The coal is placed in a hopper on the upper front end of the furnace, and is delivered in regular and graduated quantities by a roller so situated as to command the throat of the hopper. This roller rotates, so as to crush the coal to a proper size. The comminuted fuel traverses the inclined chute and falls upon the surface of the incandescent fuel on the grate, which revolves beneath. The illustration shows a tubular high-pressure boiler set in masonry. The rim of the rotary grate revolves in a trough with sand to prevent the passage of air around the edge of the grate.

Fig. 5229.



Steel's Revolving-Grate Furnace.

Brunton added a revolving scraper, which gathered up the ashes as they fell upon the ash-plate, and devices by which the rotation of the feed-wheel may be regulated to give a greater or less amount of coal, according to the requirements. It is not understood that a thermostatic arrangement was attached to graduate the amount of coal according to the heat of the furnace or the tension of the steam, or a device from the governor, which might also control the air-induction opening at the ash-pit.

In Juckes' furnace the fire-bars form an endless grate, which advances so that the fuel is gradually carried from the front to the back of the fireplace. Coal in regulated quantities is dropped from a hopper upon the front of the grate, and the air for burning the fuel passes between the bars. The whole area of the grate is covered with fuel, but, as the portion last laid on is always nearest the front, the smoke from that portion is compelled to pass over the more thoroughly ignited portion behind, where it undergoes thorough combustion, very little finding its way into the chimney.

5. Yet another method for attaining the perfect combustion of the smoke consists in injecting jets of steam into the furnace. Evans, in England, 1824, patented a method in which the steam was to be decomposed by passing through the hot fuel.

In 1844, Christian Burckhardt, of Cincinnati, consumed the smoke of a steamboat furnace by projecting fine jets of steam into its upper part.

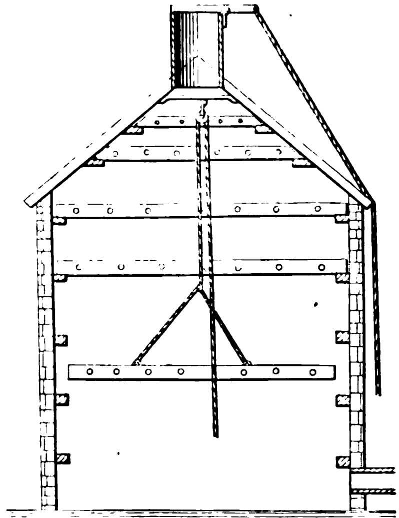
Economy of fuel being a secondary consideration on the Western waters, contrivances of this kind have met with but little attention.

Smoke-house. A building employed for the purpose of curing flesh by smoking. It is provided with hooks for suspending the pieces of meat, which are hung over a smudge or smoldering fire kindled at the bottom of the apartment.

"The Kerretani are a people of the Iberians. The hams they cure are excellent, fully equal to those of the Cantabrians." — STRABO.

In smoking on a large scale, the hams, shoulders, and sides are sometimes hung in an attic, and the smoke is conducted by pipes from the cellar, where it is made. This makes it cool on arrival, which is a great advantage. Green hickory wood is used.

Fig. 5230.

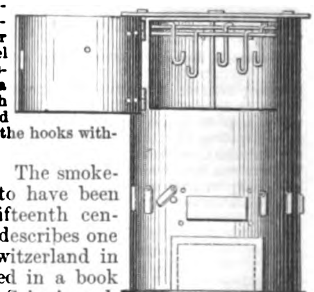


Smoke-House.

Fig. 5230 shows a smoke-house in which the beams from which the meat is suspended are held by cleats on the walls. A beam, being suspended by tackle within easy reach, is filled with meat and is then raised to its place in the house. A damper on top of the chimney regulates the draft.

Fig. 5231 is a sheet-iron portable smoke-house. It has a drawer for fire, a mica panel for observation, register air-holes, and a door above by which the meat is introduced to be suspended from the hooks within.

Fig. 5231.



Portable Smoke-House.

Smoke-jack. The smoke-jack is supposed to have been invented in the fifteenth century. Montaigne describes one he met with in Switzerland in 1580. It is noticed in a book on "Cookery," by Scippi, cook to Pius V. in 1570.

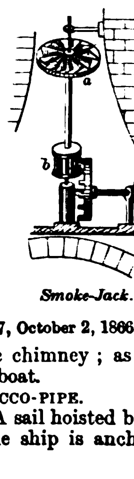
"My own jacke do carry it [a chine of beef] well." — PEPYS' *Diary*, 1663.

It was superseded by other roasting-jacks driven by animal or mechanical power, and all the jacks have, unfortunately for the meat and the consumers, been superseded by the oven, which bakes but roasts not.

The spit, so common in English kitchens in the last century, was frequently turned by a dog. The ordinary roasting-jack is called the *bottle-jack*, and has a clock-movement by which the suspended meat is turned at a moderate pace, so many revolutions in one direction and then in the opposite.

In the smoke-jack (Fig. 5232), the horizontal wheel *a* has a series of vanes or sails which cause it to be rotated by the current of smoke and heated air ascending the chimney, turning the wallower *b*, into which gears a crown-wheel that turns a pulley connected by a cord with a pulley on the axis of the spit. See also ROASTING-JACK.

Fig. 5232.



Smoke-Jack.

The principle has been applied to an engine. See Ensign's patent, No. 58,397, October 2, 1866.

Smoke-pipe. 1. A metallic chimney; as that of a locomotive, a stove, a steamboat.

2. A *smoking-pipe*. See TOBACCO-PIPE.

Smoke-sail. (*Nautical.*) A sail hoisted before the funnel of the galley when the ship is anchored

head to wind, to screen the quarter-deck from the smoke.

Smoke-stack. (*A chimney.*) The term *stack* is properly applied to a brick or stone chimney, but is not properly applicable to the funnel or furnace chimney rising above the deck of a vessel. With war-vessels the *funnel* is made telescopic, so as to be lowered during action.

The term *smoke-stack* is also applied to the chimney of a locomotive.

Smok′ing-pipe. See TOBACCO-PIPE.

Smooth-file. 1. A finishing-file, whose teeth are of a grade of coarseness between the *second-cut* and the *dead-smooth*. See ROUGH-FILE.

The number of teeth to the inch is according to the length of the file in inches.

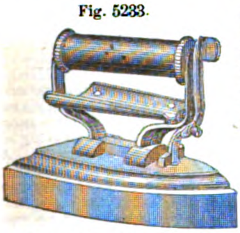
Inches..........	4	6	8	12	16	20
Cuts	112	83	72	72	64	56

The angle of the chisel in cutting is about 5° from the perpendicular.

2. The rubbing-tool used by the needle-maker in pressing and rolling a pack of wires, cut for needles, to take out of them the bend they have acquired by the coiling of the wire. See NEEDLE.

Smooth′ing-ir′on. A domestic implement, used in the laundry to smooth (iron) linen. It is heated by placing on a stove, by a gas jet, by a hot iron or charcoal fire placed within it. The various modes of heating, of attaching the handle, and devices for shielding the hand from excessive heat, give rise to many patents. See SAD-IRON.

Fig. 5233.



Smoothing-Iron with Shield.

Fig. 5234.

Egyptian Smoothing-Tool.

The shape and purpose, but not the material usually employed by us, are shown in a wooden tool found in Thebes. It was used in smoothing and pressing cloth, though Mr. Wilkinson thinks that the finish attained evidences the use of metal. Those found were about 6 inches in length, and made of hard wood.

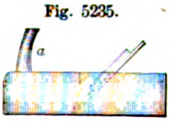
Smooth′ing-ir′on Heat′er. A heater for smoothing iron. See SAD-IRON HEATER.

Smooth′ing-mill. The polishing-mill of the lapidary. It is of tin, or wood covered with leather, revolves on a vertical axis, and is touched with rotten-stone, or other material adapted to the subject.

Smooth′ing-plane. A short plane, finely set, for finishing. It is $7\frac{1}{2}$ inches long.

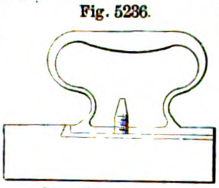
Fig. 5235 is a plane commonly used for roughing out, as the jack-plane is in England and this country. The horn *a* is held by the left hand, while the right is placed on the back of the stock. The horn is known as a *toat.*

Fig. 5235.



Smoothing-Plane.

Fig. 5236.



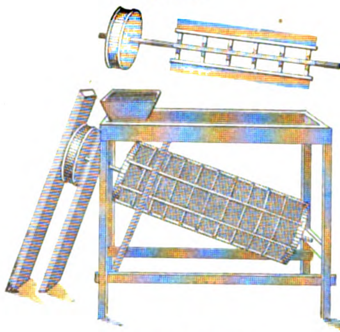
Smoothing-Stone.

Smooth′ing-stone. A substitute for a smoothing-iron, made of steatite, attached to a plate and handle of metal.

Smooth-plane. A smoothing or finishing-plane; the last used of the series of *bench-planes,* known respectively as *jack, trying,* and *smooth planes.*

Smut-ma-chine′. The smut-machine is said to have been invented by Hall, of Surry, England, and as contrived by him consists of a reticulated cylinder, inside of which are a number of brushes attached to the arms of a reel and revolved rapidly. The wheat passes in a continuous stream from the hopper above, and gradually finds its way down the inclined screen, at the foot of which it is discharged. By the action of the brushes and the current of air generated, the smut is driven through the meshes or perforations of the screen.

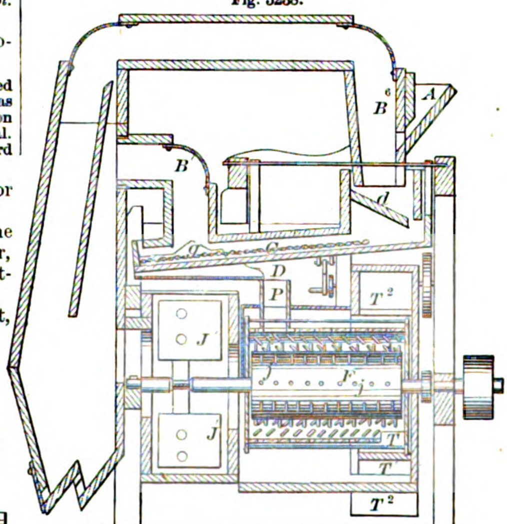
Fig. 5237.



Hall's Smut-Machine.

In the machine (Fig. 5238), the grain from the hopper *A* falls upon an inclined table *d*, and thence drops on to a vibrating trough *C*, having a roughened bottom and a transverse ridge-piece *g* to partially arrest the grain during its passage, and permit the blast from the fan *J′ J′* to act more efficiently in removing impurities, which are carried off by the

Fig. 5238.

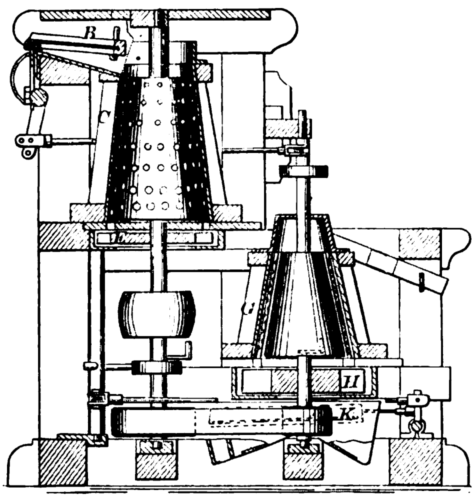


Smut-Mill.

spouts B' B^6. The grain drops on to the incline D, and is conveyed through the hopper P into an inclined receiver, where it is subjected to the action of a revolving beater F, studded with pins j j. The receiver has a series of spirally arranged slots, along which the grain is conducted to an opening T, passing into an inclined spout T', by which it is delivered into the vertical discharge-spout T^2.

In Fig. 5239, the grain is fed to the upper screen B, to remove the straw and coarse material; thence

Fig. 5239.



Smut-Machine.

it is delivered within the outer shell of the conical smutting-device C, which has at its base a fan E; thence the grain is passed to the conical brushing-apparatus G, which also has a fan H at its base; and finally it passes over a vibrating screen K to the hopper for grinding.

In another machine, a series of hopper-shaped revolving disks, with ribs on their upper sides, throw the grain centrifugally upon concentric rings, which drop it upon the next disk, until it reaches the outermost, where it is collected by a hopper, and passed to a similar arrangement on a lower level.

Snaf′fle. (*Harness.*) A bridle-bit with a joint in the middle, rings at the ends for the attachment of the reins, without *branches*, but in some cases having *cheeks* (side-bars) to keep the rings from getting inside the mouth of the horse. They are designated as *jointed*, *twisted*, or *double-mouth* snaffles, according to the construction.

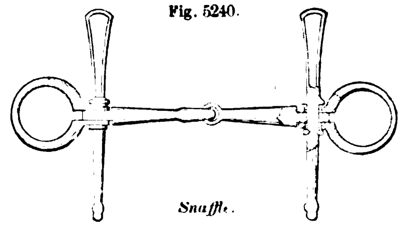
Snaffles are made heavy or light, gentle or severe. The action of pulling causes the sections to close against the gums of the lower jaw. When the pieces which form the bit are large, they are not so severe upon the mouth as when small, because the latter imbeds itself more deeply in the gums of the mouth.

The *snaffle* usually consists of 4 pieces, which are secured together by ring joints, so as to be movable on each other. The portions of the bit which meet in the middle mouth form ring-loops which engage each other. The rein-rings pass through holes in the other ends of the bit-pieces.

In Fig. 5240, the rein-rings, cheek-pieces, and jointed bars are made in separate parts, and are connected by passing the cheek-pieces through eyes, which are formed on the mouth-pieces and rings, and securing the whole together by bands or collars applied to the cheek-pieces.

The snaffle may be made more severe by coiling wire around it, or more gentle by wrapping it with leather or a band of india-rubber.

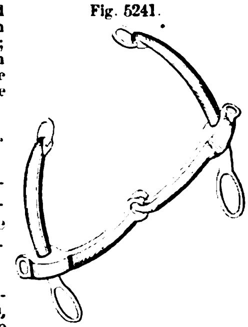
Fig. 5240.



Snaffle.

Price's bridle-bit, March 26, 1867, combines the snaffle-bit with a lever-bar, to confer power upon the bit. The headstall and reins are attached to the opposite ends of movable and sliding levers, which run through the eyes of the bit; these, as they are drawn through by the reins, increase the leverage on the jaw of the horse.

Fig. 5241.



Price's Bridle-Bit.

Snaf′fle-bit. See SNAFFLE.

Snag-boat. A steamboat with hoisting apparatus, employed on the Western rivers for removing snags.

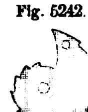
These obstructions to navigation are caused by large trees, which, being precipitated into the water, by the river undermining its banks, are borne away on the current, and occasionally get entangled, and even become firmly fixed, in the bed of the stream. Sometimes a branch of the tree is seen projecting from the water, but often no part of it is visible, the only indication of its existence being a slight ripple on the surface of the water. They have received from the boatmen of the Mississippi the names of *snags*, *planters*, and *sawyers*, bearing one or other of these designations, according to their positions and the manner in which they are fixed in the river. The term *snag* is applied to a tree firmly imbedded in the bottom, and lying at a considerable angle, with its top inclined down the stream. A *planter* is a tree firmly fixed in a nearly perpendicular position; and a *sawyer* is the name applied to a tree whose roots or branches have become entangled in the bed of the river, and whose trunk, being loose, is kept constantly swinging up and down by the current, alternately showing its head and plunging it under the surface. Sometimes several of these trees collect together in the same place, and form a small islet, which, after maintaining its position for some time, and gradually increasing its dimensions, at length attains an enormous magnitude, and often becomes an impassable barrier, extending along the river's course for many miles. This is what the boatmen call a *raft*. It generally occurs in the tributaries of the Mississippi, and not in the river itself. One instance of this is afforded by the Red River, and another by the Atchafalaya, a river flowing *out* of the Mississippi, at a point about 250 miles from the sea. The Atchafalaya raft extends over a space of 20 miles; but the river's bed, for the whole of this distance, is not filled up with drift-timber, — the actual length of the raft itself being only about 10 miles.

The *snag-boat* consists of two hulls, firmly secured to each other, at a distance of a few feet apart; and over the intervening space a deck is thrown, having an aperture left in the center. A powerful crab is placed over this aperture, from which strong chains and grapplings are suspended in the space between the two vessels. The snag-boat is propelled by paddle-wells, which, with the gearing for raising the snags, are worked by a steam-engine placed on its deck. In using the apparatus, the vessel is brought to an anchor over the snag or obstacle to be removed, and the grapplings are made fast to the pieces which are to be raised. The paddle-wheels being thrown out of gear, the engine is applied to work the crab, by which the snag is torn from its hold in the bottom of the river, and after being cut in short pieces is allowed to float down the stream.

Snail. 1. (*Machinery.*) A spiral cam.

2. (*Horology.*) A flat piece of metal of spirally curved outline, used for lifting a movable part, as the hammer-tail of a striking clock.

Fig. 5242.



Snail-Wheel.

Snail-wheel. (*Horology.*) A wheel having an edge formed in 12 steps, arranged spirally, the positions of which determine the number of strokes of the

hammer on the bell. The *snail* is placed on the arbor of the 12-hour wheel.

Snake-line. (*Nautical.*) Line used in worming a rope.

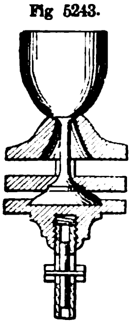
Snak'ing. (*Nautical.*) *a.* Passing a line spirally around a rope, so as to lie in the indentations between the strands. See WORMING.

b. Stoppers passed alternately from one stay or rope to another throughout their length in a parallel direction, so that if one is shot away its functions may be performed by the other.

Snap. 1. (*Harness.*) A mousing-hook for harness. See SNAP-HOOK.

2. (*Glass-making.*) An implement used in making glassware. In Fig. 5243, the central disk is movable and connected to the spring rod, by which it is drawn down upon the base of the goblet, which enters the cylindrical recess in the bed-plate.

Fig 5243.



Snap for Glassware.

3. A tool used by boiler-makers for giving the head of the rivet a round and symmetrical form before it cools but after it has been closed.

4. The spring-catch of a bracelet, book-clasp, purse, reticule, etc.

Fig. 5244.

Snap-Dragon.

Snap-drag'-on. (*Glass.*) A kind of tongs used by glass-blowers to hold their hot hollow ware.

Snape. (*Shipbuilding.*) To bevel the end of a piece of timber, so as to make it fit against a surface which it meets obliquely. This angular fitting is also termed *flinching, snying, faying*, etc., in different trades.

Snaped Tim'ber. (*Shipbuilding.*) Timber cut beveling, so that one face is narrower than the other.

Snap-flask. (*Founding.*) A two-part flask having its halves joined together by a butt-hinge at one corner and a latch at the diagonally opposite corner.

Snap'hance. The name formerly applied to the spring-lock of a fire-arm. The word and the object were derived from Continental Europe. It superseded the wheel-lock. The *snaphance* fell upon a movable piece of steel, called a *frizel*, which was placed vertically above the *pan*.

Fig. 5245.

Snap-Head.

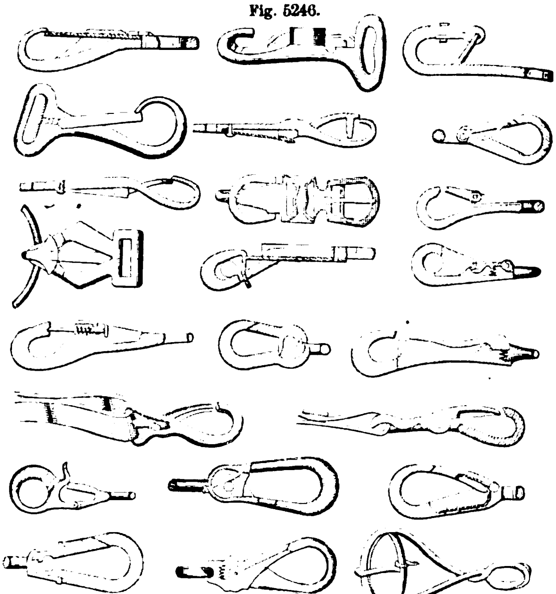
Snap-head. (*Machinery.*) *a.* A round head to a pin, bolt, or rivet.

b. A swaging tool with a hollow corresponding to the form required of a rivet. It is held over the end of the hot rivet and struck by a hammer.

Snap-hook. A hook with a spring mousing by which it is prevented from accidental disengagement with the object to which it is attached, as the bit-ring, hame-ring, or breeching-ring. The mousing formerly consisted of a spring, but a spring latch-piece is now the common form.

Fig. 5246 shows a number of forms of snap-hooks which require no particular description. In some the spring forms the latch; in others the spring actuates the latch.

Fig. 5246.

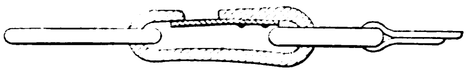


Snap-Hooks.

In Foster's machine for forming snap-hooks, February 2, 1875, a sliding frame and pawl feeds the wire into radial notches in an intermittingly revolving roulette, which, after the wire is cut off, carries it between guides to center it, and then under a griper, that holds it while the milling mechanism rounds the points. At the next movement of the roulette a plunger carries the wire out, and presses it against a former, where it is bent into U shape. Four side-dies are advanced to cross and form the sides, and two vertical plungers give a semicircular bend to the ends in reverse directions. Upon the withdrawal of these plungers, a mandrel is inserted into the loop, and a rear plunger advances and bends down the ends, so that they overlap and form a circle. The dies are withdrawn, and a pusher removes the finished article.

Snap-link. An open link with a spring, for the purpose of connecting parts of harness, chains, etc.

Fig. 5247.



Snap-Link.

Snap-lock. (*Hardware.*) A lock with a spring latch which snaps shut.

Snap'ping-tool. (*Metal-working.*) A stamping-tool used to force a plate into holes in a die.

Snare. 1. A gin; noose; trap. See TRAP.

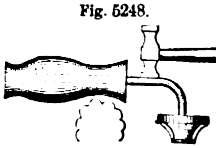
2. The gut stretched across the head of a drum.

Snare-drum. (*Music.*) A small military drum, having a catgut string stretched across its lower head, to impart a certain quality to the tone. The larger drum is called the *bass*-drum.

Snarl'ing. (*Metal-working.*) A method of raising hollow works in metal by percussion.

Snarl'ing-ir'on. 1. (*Metal-working.*) A tool used for fluting or embossing works in sheet-metal, when, from their shape, swages cannot be applied. Its two ends are oppositely curved, one being held by the jaws of a vise, and the other inserted through the mouth of the vessel and applied to the part to be raised. The iron is struck with a hammer, and the reaction gives a blow within the vessel, throwing the metal out in form corresponding to that of the tool, whether angular, cylindrical, or globular. One individual is

Fig. 5248.



Snarling-Iron.

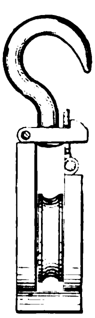
generally required to hold the work while another strikes.

2. (*Nautical.*) A tool used in the operation of snarling.

Snatch. (From *notch.*) An open lead for a rope. (See SNATCH-BLOCK.) If it be without a sheave, it is known as a *dumb-snatch*, such as are provided on the bows and quarters for hawsers.

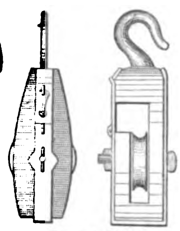
Snatch-block. (*Nautical.*) A single block which has an opening (*notch*) in one cheek to receive the bight of a rope. The block is iron-bound, with a swivel hook. The portion of the strap which crosses the opening or *snatch* in the shell is hinged, so as to be laid back when the bight of the rope is to be inserted, when warping the ship. This saves the trouble of reeving the end through.

Fig. 5249.



Snatch-Block.

Fig. 5250.



Snatch-Block.

Large blocks of this kind are called *viol-blocks* or *rouse-about blocks.*

Fig. 5249 is another form of snatch-block.

Snath. (*Husbandry.*) The helve of a scythe. The handles are *nibs.* Also known as a *sneath* or *snid.*

Snell. A short line of horsehair or gut by which a fish-hook is attached to a line. A *snood.*

Snick. 1. (*Fiber.*) A knot or irregularity on yarn, removed by passing it through a slotted plate.

2. (*Fur.*) A small snip or cut, as in the hair of a beast.

Snif'fle-valve. See SNIFTING-VALVE.

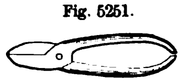
Snift'ing-valve. (*Steam-engine.*) A valve commanding the valve-way through which the air and water are expelled from a condensing steam-engine, when steam is *blown through* the engine.

This is the first operation in starting a condensing engine.

Snigg. (*Nautical.*) A kind of sailing-vessel.

Snip. A small hand-shears for cutting metal.

Fig. 5251.



Snip.

Snipe-bill. 1. (*Joinery.*) A narrow, deep-working molding-plane, used for forming quirks.

2. (*Vehicle.*) A rod by which the body of a cart is bolted to the axle.

Snoff. (*Mining.*) The slow-match for igniting the train in blasting.

Snood. A hair-line, gut, or silk cord by which a fish-hook is fastened to the line. A *snell.*

Snore-hole. (*Mining.*) The hole in the *wind-bore* or lower stock of a mining-pump, to admit the water.

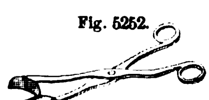
Snot'ter. (*Nautical.*) *a.* A becket on a boat's mast, to hold the lower end of the *sprit* which elevates the peak of the sail.

b. A rope going over a yard-arm, used to bend a tripping line to in sending down the topgallant and royal yards.

Snout. (*Hydraulics.*) The nozzle of a hose.

Snout'er. A cutting shears with one curved blade approximating to the shape of a hog's snout, and used for removing at one cut the cartilage wherewith he roots.

Fig. 5252.



Snouter.

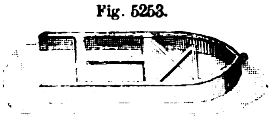
Snout-ring. A ring or staple placed in the nose of a hog to deter him from rooting.

Snow. (*Nautical.*) A brig-rigged vessel, whose *driver* is bent to rings on a supplementary mast just abaft the mainmast.

Snow-plow. This implement is used to clear a track of snow, and is of two kinds; one is adapted to be hauled by horses or oxen on a common highway, and the other to be placed in front of a locomotive. A variety of the latter is adapted for street railways.

The snow-plow for ordinary country roads has long been in use in Northern countries, and the Norwegian plow affords a good example of its general construction. The front is shaped like the bow of a boat, and the sides are braced by an internal framework. The bottom, top, and rear are open. The team is hitched to the ring on the upper edge of the bow, and the snow is divided to right and left as the implement is drawn along, being compacted on either side. A more rude implement is shaped like the letter A, and is drawn along by its apex.

Fig. 5253.

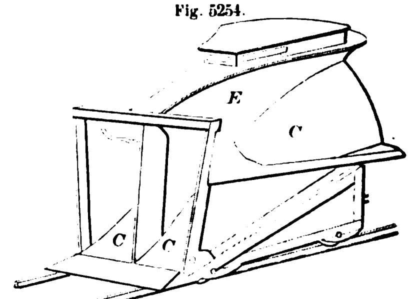


Norwegian Snow-Plow.

For railway purposes the snow-plow is adapted to the character of the country, the amount of snow-fall, tendency to drift, etc. On the Sierra portion of the Pacific Railway and on the Grand Trunk Railway of Canada, great preparations are made in advance of the winter season, and their snow-plows assume gigantic proportions. The depth of the snow is frequently so great that it cannot be compacted to right and left by a prow-shaped implement, but it becomes necessary to give the plow a double action; the upper portion of the snow is lifted and thrown to the right and left upon the snow on each side of the track, while the lower portion of the snow-plow is prow-shaped, and divides the lower stratum of snow, compacting it on each side against that adjacent.

In Fig. 5254, the plow is supported upon an inclined plane on a truck, and its angle is adjustable; it has two nearly vertical cutters, which cut the sides of the track, and a central one *E* for dividing the mass of snow which is carried up the two inclined spiral plates *C C* and discharged on top of the snow-bank at each side.

Fig. 5254.



Two-Story Snow-Plow.

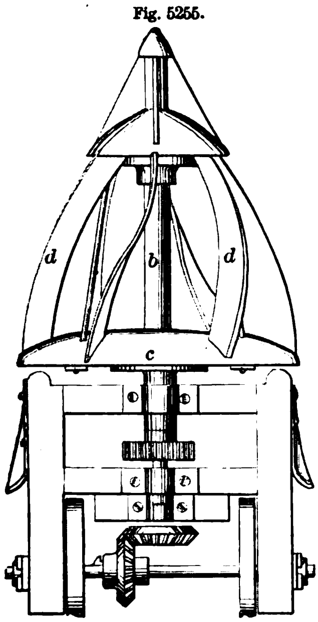
A snow-plow for the Union Pacific Railway, built at the shops in Omaha, is probably the largest and most powerful in the world. The platform on the trucks is 22 feet long, 10 feet 6 inches wide, and is composed of solid oak timbers, held together by iron bolts $1\frac{1}{4}$ inches in diameter, which run crosswise. This solid bed is bolted to the transom beams. The inclined side, placed on the platform, is 22 feet long, slopes at an angle of 30°, and is bolted to the bed and supported from behind by inclined posts. The entire length, from the rear of the platform end of the slide, is 32 feet. The slide is ironed, and an immense plow of the ordinary shape, 18 feet long, 11 feet wide, 5 feet high, and covered with iron $^3/_{16}$ of an inch thick, is placed upon it. On the point of this plow there is an iron plate, steel-pointed, 11 feet long and 4 feet wide. This plate, of course, runs across the track, and only 1 inch above it. The rear of the platform is boxed in, making a room 12 feet high, 11 feet wide, and 10 feet long, for the purpose of keeping the snow out. It is furnished with a door, so that it can be loaded if necessary.

The plow weighs 50 tons, and is operated by three of the heaviest engines on the road. The cost was over $5,000.

In another plow the snow lifted by the plowshare is raised and carried rearward by an endless apron.

The plow (Fig. 5255) consists of a series of spiral

Fig. 5255.

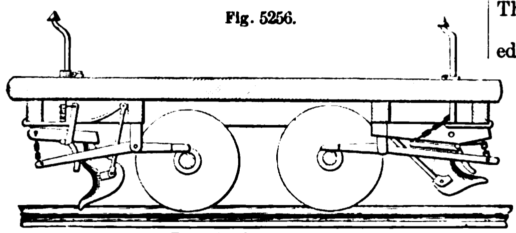


Revolving-Blade Snow-Plow.

blades *d d* connected to a back plate *c* and a pointed front plate, carried on the shaft *b* rotated by gearing from the front axle of the truck; curved side-wings and bottom-scrapers may also be attached to the truck for completely clearing the track.

Fig. 5256 is a snow-plow adapted for street-railways, one or the other being lowered into action according to the direction of motion of the car. The position of the plow, when down, is maintained by a spring, which allows it to yield to solid obstructions.

Fig. 5256.

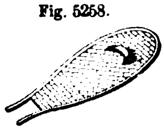


Snow-Plow for Street-Railways.

Snow-shed. A protection for a railway-track in exposed situations where snow-drifts are liable to accumulate on the track and prevent travel.

Snow-shoe. A light frame made of bent wood and interlacing thongs, used to give the wearer a broader base of support when walking on snow. The *tread* of the shoe is formed of strips of raw hide, hard-twisted twine, or, among the Indians, of deer-sinews. In use, the toe is placed beneath the strap and the foot rests on the thongs; as the heel rises in walking, the snow-shoe is not raised, but as the foot is lifted, the toe elevates the forward end of the snow-shoe, which is then dragged along on the snow as the leg is advanced.

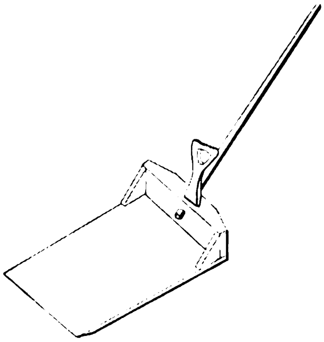
Fig. 5258.



Snow-Shoe.

Snow-shov'el. A wooden or metallic shovel for cleaning off pavements, garden-walks, etc. In the example, the hold for the left hand is secured to the stock of the blade by the stale, which affords a hold for the right hand. The parts are detachable for convenience in stowage.

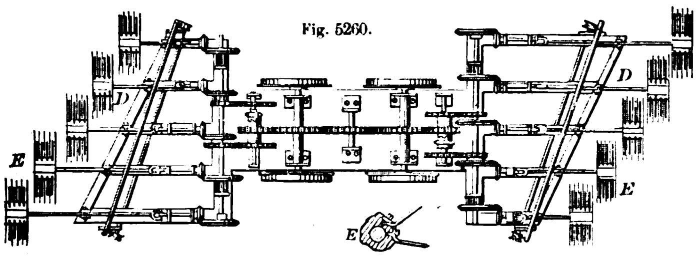
Fig. 5259.

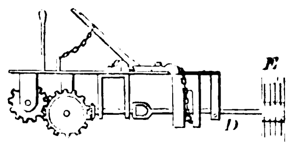


Snow-Shovel.

Snow-sweep'er. A vehicle or apparatus adapted for removing snow from paved streets. The machine (Fig. 5260) consists of a truck carrying a sweeping apparatus at each end, comprising a series of wire brushes *E E* on rods *D D* of unequal length, so that each is slightly in advance of its neighbor, and the whole completely covers the space to be swept. The rods are rotated by clutch connection with the truck-wheels, and have universal joints, so that they, with their frame, may be lifted from the ground when not in use.

Fig. 5260.





Snow-Sweeper.

Fig. 5257

Snow-Shed in the Sierra Nevada.

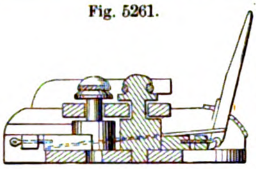
Snub. (*Nautical.*) To check a cable or other rope suddenly when running out.

Snub'ber. (*Nautical.*) A cable-stopper. A device for *snubbing*, that is, stopping the cable from running out.

Snub'bing-line. (*Nautical.*) The line on the bow of a canal-boat, which is taken one or two turns around a post or bollard on the land to check the forward movement of the boat in entering a lock.

Snub-post. (*Nautical.*) A form of bitt or mooring-post on a raft or canal-boat or flat-boat, used for winding the hawser around whereby the raft or boat is brought to a mooring. The same is

Fig. 5261.



Snub-Post for Rafts.

done on steamboats by making a figure-of-eight of the cable around the horns of a becket or kevel on the gunwale in checking the course of a vessel and bringing it up against the dock, easing away the cable when the strain is too severe. In the example, the hawser is wound in serpentine order round several posts standing in two rows, and a hand lever and rod bring a brake into action to check the running of the rope by friction applied to the snubbers. A *head-fast.*

Snuff'er. A shears for cutting the wicks of candles.

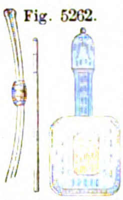
"A new-fashioned case for a pair of snuffers, which is very pretty" — PEPYS' *Diary*, 1668.

Snuff-mill. A machine consisting of a circular arrangement of mortars around a central axis, which is occupied by a master wheel giving motion to the rolling pestle in each mortar.

The snuff-mills of Holland are on a very large scale, and are impelled by wind.

Although Columbus found smokers in the Antilles, and Pizarro first beheld chewers in Peru, yet Brazilians were the first and best fabricators of snuff. Fig. 5262 illustrates their milling and sniffing apparatus. The figure represents a slab of rosewood with a depression for holding the dried leaves while being triturated with a stick of the same material. The friction of the two pieces of odoriferous wood develops a pleasant aroma, which impregnates the powder. While yet warm with the friction, the snuff is inhaled by a double pipe, also shown in the figure. It consists of a double tube formed of two light bones obtained from the wings of a young crane, united by a thread and terminating at their upper ends in small wooden bulbs. The plain ends of the tubes being inserted in the powder, and the others inserted into the nostrils, a smart inhalation distributes the scented dust over the membrane of the nose.

Fig. 5262.



Brazilian Snuff-Mill and Sniffers.

"Take out your box of right Brazil." — POPE.

The taking of snuff — as a habit — is said to have been first adopted in Europe by Catherine de Medici. It was called *herbe de la reine*, 1560

Snug. 1. (*Machinery.*) A small rib, lug, or marginal ridge, cast on to a plate and acting as a lateral support to keep an attached object in place; as, on the edge of a bracket-sole. See BRACKET.

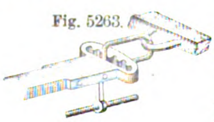
2. (*Steam-engine.*) One of the catches on the eccentric pulley and intermediate shaft, for the purpose of communicating the motion of the shaft through the eccentric to the slide-valves.

Snug'ging. The operation of rubbing down the fuzzy fibers of rope to improve its finish. Known also as *slicking* or *finishing.*

Sny. (*Shipbuilding.*) *a.* A gentle bend in timber curving upward. If it tend downward, it is said to *hang.*

b. The trend of the lines of a ship upward from amidship toward the bow and the stern.

Fig. 5263.



Soam.

Sny'ing. (*Shipbuilding.*) A curved plank worked edgeways into the bow of a vessel.

Soam. A chain by which the leading horses are hitched to a plow. To preserve the line of draft and not draw down the nose of the plow-beam, the *soam* is supported by a hanger below the clevis.

Soap A compound of fatty substances with soda or potash. The processes of making soap are chemical rather than mechanical, and we refer the reader to Ure and Muspratt. A historical account of soap may be found in Beckmann's "History of Inventions."

The Hebrew word rendered *soap* and the fuller's soap both refer to an alkali, and the first distinct mention of soap, now extant, is probably the reference to it by Pliny, in his "Natural History." He speaks of it as the invention of the Gauls, who also discovered the useful properties of brewer's yeast in bread; they were the first to invent a reaping-machine, which was in use from the time of Pliny to that of Palladius, about 400 years. Pretty well for the Gauls. Their record is superb.

The Gallic soap, 18 centuries back, was made from tallow and wood ashes, beechwood ashes being preferred. Beech is a very common wood in France, as well as in England and the United States. A soap-manufactory has been exhumed in Pompeii, the apparatus and manufactured soap in tolerable preservation.

Soap is occasionally mentioned by writers from the second century down (Athene, A. D. 193; Ætius, fourth century); but the more cleanly Saracens, who invented the shirt, seem to have been among the first to popularize the use of soap as a detergent for clothes, and as an external cleansing application.

Soaps are divided into *hard* and *soft;* in the former, soda, and in the latter, potash, is used as the base. A hard soap may be made with potash if a solid fat be employed, but soda soaps are always harder than potash soaps with the same fatty substance. The proportions of alkali required to effect saponification, when dry and pure material is employed, vary from 10 to 14 of soda, or from 15 to 20 of potash, to each 100 parts of the fatty substance employed. Tallow and soda are generally employed for white soaps in Northern climates, but where, as in the South of France, the olive-tree abounds, inferior olive-oil is used. The celebrated brown Windsor soap contains about 10 per cent of this oil, mixed with the tallow.

Marine or *salt-water* soap is made from cocoanut or palm oil, and has the property of being soluble in salt water, which renders it valuable on board ship. It solidifies with a much larger quantity of water than other soaps, samples having been found containing 75 per cent of water.

White soap is, in general, too hard for domestic use, but forms a basis for many toilet and fancy soaps.

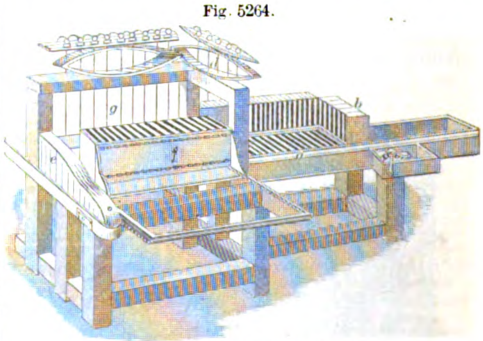
Transparent soap is made by evaporating a soda or potash soap after dissolving it in alcohol; marbled soap, by adding a little sulphide of iron. Silicated soap is made by adding a small quantity of silicate of soda or of alumina to ordinary hard soap.

Colored soaps are produced by mixing mineral colors with the fluid mass; marbled soaps, by rubbing up the coloring ingredient with a little olive-oil or soap, which is then stirred in with a palette-knife, so as to impart a wavy appearance.

There are many other names, geographical, chemical, etc., as Castile, carbolic, etc.

Soap Bar'ring and Cak'ing Ma-chine'. The machine (Fig. 5264) has two followers operated by

Fig. 5264.



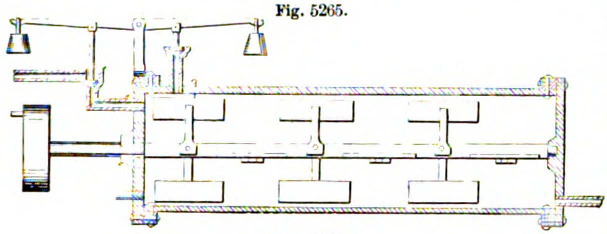
Soap Barring and Caking Machine.

rack and pinion motion and traversing on frames at right angles to each other; a slab of soap is placed on the rollers *a* and carried by the follower *b* against a series of vertical wires *d*, which divide it into bars; by a farther movement of the crank, these are deposited upon the second frame *e*, where the follower

f operates to press them sideways against the vertical wires *g*, dividing the bars into cakes.

Soap-boil'er. A pan for boiling the materials for soap. The example (Fig. 5265) is a closed vat

Fig. 5265.

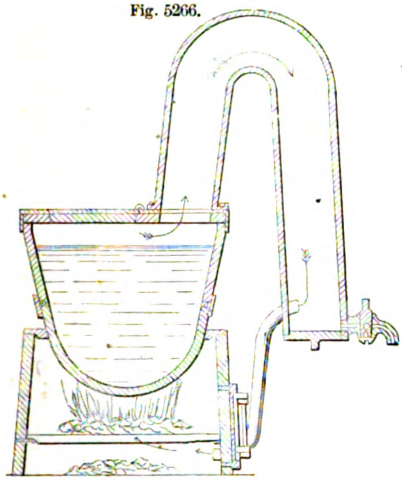


Soap-Boiler.

with rotary stirrers for agitating and commingling the materials under heat and pressure.

Fig. 5266 is a soap-boiler having a large pipe which receives the vapors rising from the kettle, condenses

Fig. 5266.

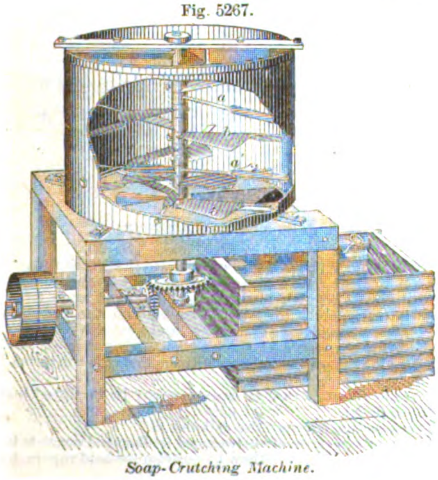


Soap-Kettle.

the watery matters, and passes the inflammable vapors under the grate-bars.

Soap-crutch'ing Ma-chine'. An apparatus

Fig. 5267.

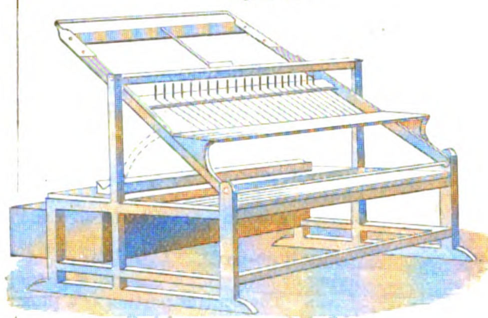


Soap-Crutching Machine.

for *crutching* (mixing) soap. That illustrated consists of an upright cylinder containing a number of radial fixed arms *a a'* and spiral wings *b b'* on a vertical shaft rotated by gearing. The soap is let into the top of the tank, and the spiral arms, being set in motion, act as screws, lifting the heavier materials from the bottom toward the top, and thoroughly intermingling the mass without forming air-bubbles. Any clippings and trimmings are also cut to pieces and incorporated.

Soap-cut'ting Ma-chine'. Fig. 5268 is a machine commonly used in England for dividing soap into bars. A slab of soap is placed in an inclined position and subjected to the cutting action of a series of wires fixed in a pivoted frame; by depressing one end of this frame, the wires cut the soap into bars, which remain on a shelf attached thereto when the frame is again lifted.

Fig. 5268.



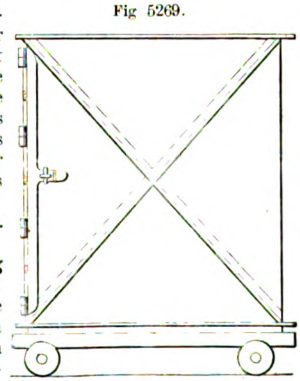
Soap-Cutting Machine.

Soap-frame. A box to hold soap and retain it till it acquires a certain degree of solidity.

It consists of a series of rectangular frames, which are built upon each other to the required hight, and clamped together by screw-rods, so as to make water-tight joints; or of a box whose sides are locked together and to the bottom. In either case the sides or sections are removable from the body of hardened soap, so as to leave it standing, in order to be cut into bars by a wire. See SOAP-CUTTING MACHINE.

In Fig. 5269, the base is mounted on wheels, and has a rabbet around its upper edge containing a rubber packing, against which the sides are clamped. The frame is formed of plates bent at right angles and joined together at diagonal corners by hinged clamps.

Fig 5269.

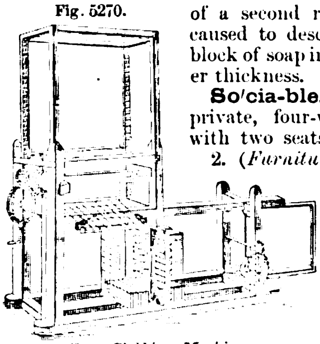


Soap-Frame.

Soap-ket'tle. See SOAP-BOILER.

Soap-slab'bing Ma-chine'. Fig. 5270 has a carriage reciprocated by a rack and a pinion operated by a hand-crank; the soap is placed on the carriage and run beneath a horizontal frame provided with wires, which are adjustable as to distance apart; on turning a crank, the frame is, by means

Fig. 5270.



Soap-Slabbing Machine.

of a second rack and pinion, caused to descend, cutting the block of soap into slabs of proper thickness.

So'cia-ble. 1. (*Vehicle.*) A private, four-wheeled carriage with two seats facing.

2. (*Furniture.*) A kind of couch with a curved S-shaped back, for two persons who sit partially facing each other.

Sock. 1. (*Husbandry.*) The movable share of a plow, so called from its being slipped on to the point of the *sole*.

2. (*Wear.*) A short hose for the foot.

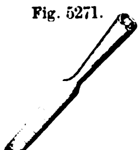
Sock-dol'a-ger. A fish-hook having a supplementary spring hook to catch the fish which touches the bait. See *f*, *i*, *l*, Fig. 2000, page 872.

Sock'et. A tubular recess in which an object is fitted.

The acetabulum of a ball in that form of universal joint.

Sock'et-bolt. (*Machinery.*) One passing through a thimble or sleeve between the parts bolted together.

Fig. 5271.



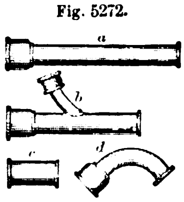
Socket-Chisel.

Sock'et-chis'el. A stout chisel employed for heavy mortising and having a hollow tang to receive the handle.

Sock'et-drill. A drill for chamfering or enlarging a hole to a given depth. The central portion is a plug which occupies a hole previously made.

Sock'et-pipe. A pipe with an enlarged end or branch to receive the end of a connecting pipe, and hold the clay, lead, or other packing which unites the two, to make a water or gas tight joint.

Fig. 5272.



Socket-Pipes.
a, Length of Socket-Pipe.
b, Branch Piece.
c, Connecting Piece.
d, Elbow.

Sock'et-pole. (*Nautical.*) An iron-shod pole used in propelling boats.

So'cle. (*Architecture.*) A plain block or plinth, forming a low pedestal to a statue or column; or a plain face or plinth at the lower part of a wall.

So'da-ap'pa-ra'tus. In the ordinary process of preparing carbonate of soda, the sulphate of soda derived from common salt, treated with sulphuric acid, is heated with chalk and slaked lime or coal. This is known as the Leblanc process.

For a century past efforts have been made to accomplish the direct conversion of the salt into soda by means of various reagents, as oxide of lead, bicarbonate of magnesia, caustic lime, alumina, silica, sesquioxide of chromium, or hydrofluo-silicic acid; but without success on an extended scale.

The "ammonia process," which is now being adopted to a considerable extent in Germany, France, England, and elsewhere, is based upon the action of bicarbonate of ammonia upon a concentrated solution of chloride of sodium, by which the greater part of the solution is precipitated as bicarbonate of soda, chloride of ammonium remaining in the solution: this is treated with caustic lime, reconverting the chloride into ammonia, which is bicarbonated and employed to decompose another portion of the salt solution.

In 1837 Bell, and in 1838 Dyer and Hemming, in England, patented processes in which ammonia was employed.

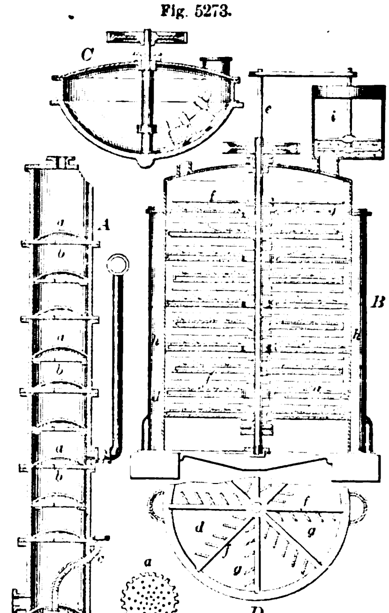
In 1854 Tuerck, and subsequently Schloesing, obtained French and English patents for similar processes, under which attempts were made to manufacture on a large scale, but proved unprofitable.

Improvements were afterward made by Margueritte and De Sourdeval of Paris, and Young of Limehouse, Great Britain, and in 1867 soda produced on the large scale was exhibited at the Paris Exposition by Solvay & Co. of Belgium. The process employed by them is as follows: —

A strong brine is prepared in a reservoir divided by upright partitions into six or more compartments, so connected that a stream of water flows in at the bottom of the first, out at the top of the second, into the bottom of the third, and so on until it becomes saturated with salt; on passing into the last compartment, which is larger, it is diluted by a stream of fresh water to the density of 23° or 24° B., and filtered. It thence flows to the bottom of a second vessel, higher than it is wide, made of tinned iron, or lead lined with wood, and having a perforated bottom, through which the gaseous ammonia enters and is absorbed as it rises through the brine. The liquid increases in volume, its density decreasing to 16° or 13° B. On reaching a certain hight it is known to be saturated, and is allowed to flow through a cooler into the absorber *A* at a point near midway of its hight. This is a cylinder from 35 to 50 feet high, and is divided by a number of perforated segmental plates *a*, beneath which are other flat plates *b* having fewer perforations, the object being to permit the carbonic-acid gas, forced in at a pressure of $1\frac{1}{2}$ to 2 atmospheres through the pipe *c*, and also the non-saturated liquid to ascend, but prevent it from descending to mix with the saturated portion at the bottom. The expansion of the gas prevents the heating which would otherwise ensue. The liquid, saturated with carbonic acid, is drawn off at intervals of half an hour, and the bicarbonate of soda separated by means of a vacuum filter. The remaining liquid, a chloride of ammonium, is then heated with caustic lime, chloride of calcium being formed while the ammonia is expelled and re-collected, or magnesia is employed for this purpose; the resulting chloride of magnesium is heated with water; when hydrochloric acid is given off, leaving caustic magnesia, which may be again employed.

The bicarbonate thus formed is reduced to the ordinary carbonate of commerce by means of the cylinder *B*, having a number of horizontal plates *d* with openings at the center and periphery. A vertical axis *e* passes through the cylinder, and has arms *f f* provided with blades *g g*, so arranged as to force the material alternately toward the center and the periphery of the plates. The plates *d* are hollow, and heated by steam or hot gas entering through *h h*; the bicarbonate is put in at *i*, and by the time it reaches the bottom of the cylinder is converted into the dry protocarbonate.

Fig. 5273.



Ammonia-Soda Apparatus.

A kettle *C* heated over an open fire may be employed instead of the cylinder.

D is a section through the cylinder *B*.

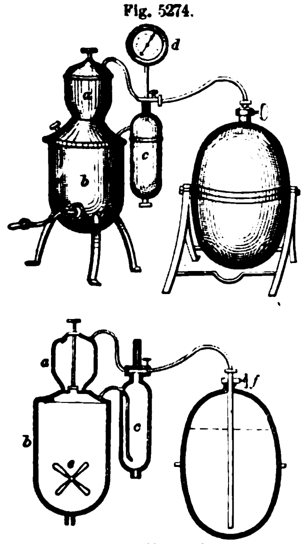
A new process recently introduced in England consists in decomposing chloride of sodium by sulphurous-acid vapors drawn

directly from the pyrite burners. This does away with the lead chambers usually employed, which are costly to build and keep in order. The sulphate of soda produced is reported to be very pure.

Another method of preparing soda and soda salts is that used at Natrona, Pa., and consists in treating the mineral cryolite, which is a double fluoride of sodium and aluminium. This is treated in a reverberatory furnace with quicklime, producing calcium fluoride and aluminate of soda, which is lixiviated out. The alumina is precipitated by carbonic acid, and used for preparing alum and sulphate of alumina. The carbonate of soda is crystallized to form sal-soda, which is then bicarbonated in the usual way. The soda from this source is very pure, and is largely used for making glass. The calcium fluoride is used as a flux for metals. In this cryolite process all the products are utilized. See also SODA-FURNACE; SODA-FOUNTAIN; AËRATOR; FOUNTAIN.

So'da-foun'tain. A vessel for containing soda-water or water charged with carbonic-acid gas under high pressure, and provided with pipes and valves for drawing it off as required. Soda-fountains are usually made of copper, and should be lined with silver to prevent corrosion. Steel is also employed.

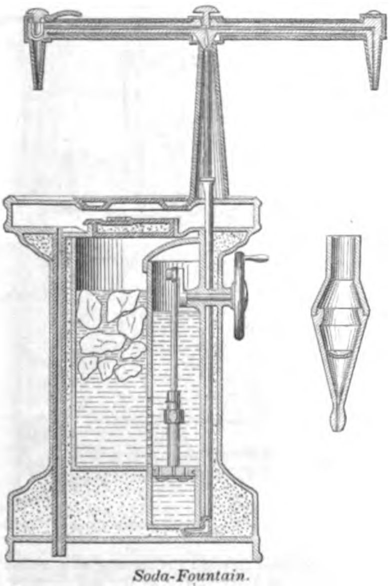
Fig. 5274.



Soda-Fountain.

Fig. 5274 illustrates a simple apparatus for generating the gas and charging the fountain. The generator *a b* consists of two parts communicating by a valved opening. The lower part is partially filled with chalk or other nearly pure carbonate of lime, the upper with sulphuric acid. On opening the valve by turning a small hand-wheel, the acid is brought in contact with the chalk, which it decomposes with the evolution of carbonic-acid gas; this is passed through a purifier *c* containing some material which will remove any deleterious matters from the gas, and provided with a gage *d*, which indicates the degree of pressure in the vessels. The carbonate is kept in motion by a rotary stirrer *e*, and when the desired pressure is attained, the cock *f* is opened, permitting the gas to flow into the fountain *g*, which has been previously partially filled with water, in which a small quantity of soda is, in some cases, dissolved. Pure water is, however, usually employed, and a flavoring sirup added when the fluid is drawn. See FOUNTAIN, Fig. 2086, page 911.

Fig. 5275.

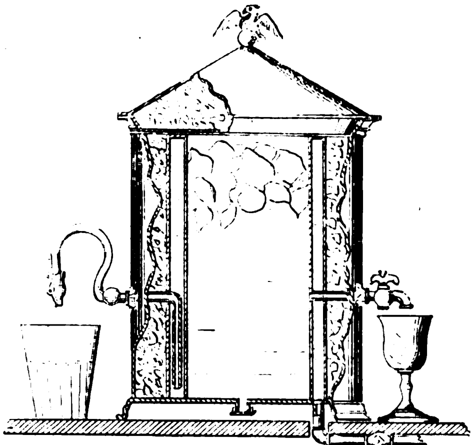


Soda-Fountain.

Fig. 5275 is a portable arrangement for village or picnic use, in which the aëration of the water is produced by the action of acid on an alkali in a chamber near the nozzle. The pump-cylinder is guarded by a perforated partition from the ice-chamber. The water is forced by a piston to the main pipe, the delivery ends of which are respectively a nozzle for plain ice-water, and a nozzle in which an effervescent powder lies upon a perforated diaphragm in the discharge-cup.

In Fig. 5276, the soda-water passes through the annular space between an ice-chamber and an outer case containing some non-conductor of heat. Discharge-faucets communicate with the soda-water reservoir and the ice-chamber. See SODA-WATER APPARATUS.

Fig. 5276.

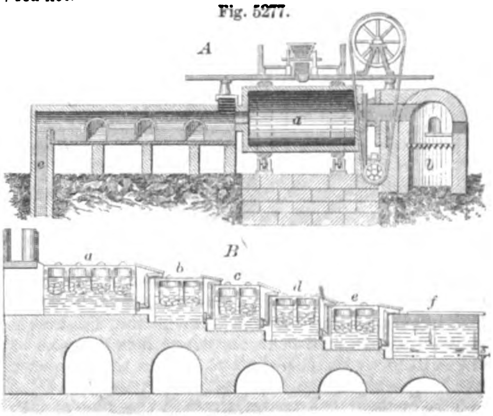


Soda-Fountain.

So'da-fur'nace. A furnace for converting sulphate of soda, obtained by treating common salt with sulphuric acid, into the carbonate. This is effected by fusing the sulphate in combination with chalk and slaked lime or small coal, — according to Leblanc, 100 parts sulphate, 100 chalk, and 50 slaked lime, — but the proportions are varied.

_A_ (Fig. 5277) represents the rotary furnace used for the purpose. It consists of an iron cylinder _a_ lined with fire-clay and having an opening at one side into which the charge is dumped from a wagon above, the cylinder having been previously heated red-hot.

Fig. 5277.



Soda-Furnace.

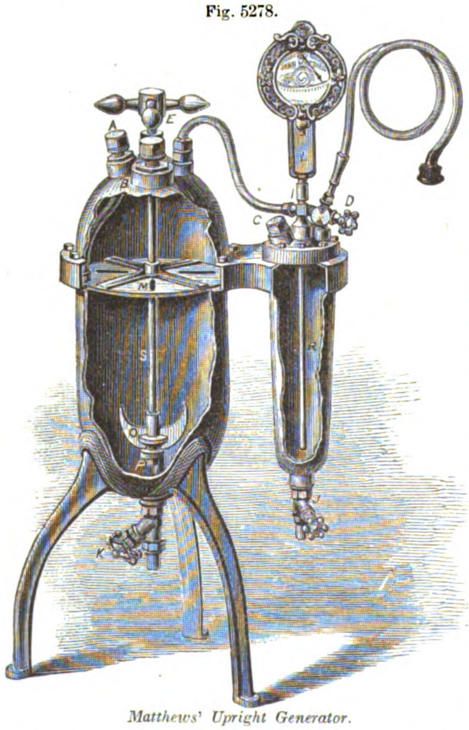
The opening is then closed, and the cylinder, which is provided with exterior ribs resting on friction-wheels beneath, is caused to make a few semi-rotations until the mass inside fuses, when a slow rotatory motion is maintained until the operation is completed. The rotation is effected by suitable belting and gearing, and during the process the heat is maintained by the products of combustion from the furnace *b*, which pass through the cylinder from end to end, and are carried off by the flue *c*. The charge in England is usually about 14 cwt. On the Continent, where the reverberatory furnace is in general use, much larger quantities are employed.

The crude soda is refined by lixiviation. *B* represents Desorme's apparatus for this purpose. It consists of a number of tanks *a b c d e* (usually 12 or 14 are employed) connected by a series of bent pipes ascending from the bottom of each vat to the top of that next below it in the series. The tanks are filled with warm water, and in *e* are placed two perforated vessels filled with pulverized soda; at the expiration of 25 minutes these are removed to *d* and replaced by others; the vessels are thus transferred consecutively from the lower to the higher vats until all are filled, when the first are removed, drained, and emptied. Each time that fresh soda is placed in the vat *e* an equal quantity of water is added to the upper vat, causing a transference of the same amount of lye from each vat to the one below it, until finally received in the clearing-tank *f*, where any impurities are deposited.

So′da-pa′per. A paper made by saturating filtering paper with carbonate of soda. Used for inclosing powders which are to be ignited under the blowpipe, so that they may not be blown away. Also used as a test paper.

So′da-wa′ter ap′pa-ra′tus. Fig. 5278 shows an upright carbonic-acid-gas generator. The acid and water are charged through the bung *A*, and are conducted by a pipe to below the diaphragm *M*, on

Fig. 5278.



Matthews' Upright Generator.

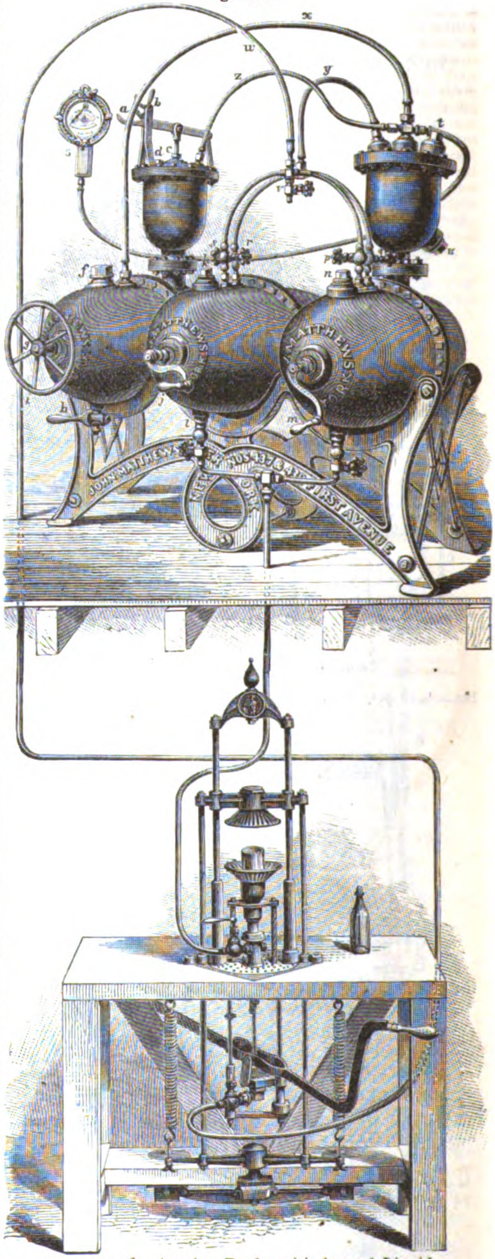
which the marble poured through the bung *B* rests. On turning the handle *E*, a four-winged valve causes this marble to drop through slits in the diaphragm into the dilute acid beneath, where it is diffused by the agitator *O* on the shaft *S*. *K* is the generator discharge-valve.

The evolved gas passes through the pipe *C* into the washer *R*, which is charged through the bung *C*, and, after passing downward through the purifying liquid, is conducted to the fountain by a pipe, to which it may be admitted by the valve *D*.

Fig. 5279 illustrates a Matthews apparatus for aërating beverages, having a horizontal generator and two stationary fountains in connection with an apparatus for charging bottles fitted with gravitating stoppers.

Each fountain is about two thirds filled with pure cold water through the apertures closed by the plugs *k n*, which are then inserted and screwed home. The gas-washer is, in like manner,

Fig. 5279.



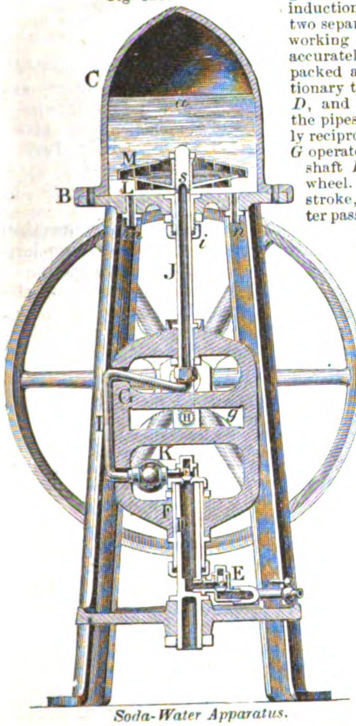
Apparatus for charging Bottles with Aërated Liquid.

about two thirds filled through the opening at *t*, which is then also closed. The discharge-valve *e* of the acid chamber is then

closed by depressing the lever *a*, which is locked by a cam *b*, and sulphuric acid is poured in through a bung *d*. Water is poured into the generator through the bung *f*, and afterward marble, and the two are mingled together by turning the hand-wheel *i* on the agitator. The lever *a* is raised to open the valve *c*, which admits acid into the generator, and the agitator turned until the required pressure is indicated by the gage. The gas passes by the pipe *a* through the washer, and by turning the valve *s* is admitted to the middle fountain, where the agitator is set in operation by turning the handle *j*, thoroughly intermingling the gas and water. Then, through the medium of the stop-cock *r*, connection is made with the bottling-machine. This should be located at least six feet lower than the generating apparatus. The bottle is placed neck downward in the socket of the machine, and is secured by depressing a treadle. Elevating the hand-lever inserts a tube within the neck of the bottle, and, by opening a gas-valve beneath the machine, charges the bottle with gas from the top of the fountain above. The lever is then depressed, and a cock on a pipe leading from the lower part of the fountain is opened, by which the bottle is filled with aërated water. When the middle fountain is emptied, the cock *s* is closed and *q* opened, thus utilizing the remaining gas in that fountain to charge in part the end one; *r* and *q* are then closed and *p* opened to complete the charge directly from the generator. When the proper pressure is thus attained, the cock *q* is opened, permitting the gas and water to flow to the bottling apparatus as before. The bottling-machine is thus alternately put in connection with each of the fountains of the apparatus.

In Matthews' improvement on the "Bramah" apparatus (Fig. 5280), water and gas are admitted to the induction-tube through two separate pipes. The working cylinder *F* is accurately fitted and packed around the stationary tubular plunger *D*, and together with the pipes *I J* is vertically reciprocated by a yoke *G* operated by the crank-shaft *H* of the hand-wheel. At each upward stroke, the gas and water pass through an upwardly opening valve *c*, into the plunger *D*, and at the down stroke a valve at top of the plunger lifting, they are conveyed upward through *I J* and discharged through a series of holes near the top of the latter, which passes through a stuffing-box in the base-plate *B*, and carries two disks *L M*, having scroll-shaped passages beneath, with their spirals arranged in reverse directions; the gas and water circulate around the lower one of these, and are conducted to the other, where, after circulating in the opposite direction, they escape through a central discharge orifice into the condenser *C*. This circulatory movement, together with the churning reciprocatory motion of the disks, tends to insure the complete aëration of the water. The condenser is provided with suitable outlets through the bed-plate for the attachment of a pipe leading to the bottling-apparatus and a pressure-gage or safety-valve. The pressure of gas in the condenser assists the down stroke of the pump, and there are no joints above the water-line *a* to be made gas-tight.

Fig. 5280.

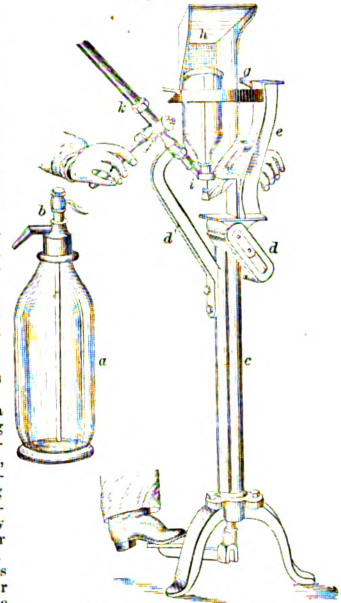


Soda-Water Apparatus.

Matthews' method of making vessels for containing gases and liquids under pressure consists in forming the cylindrical body of several thicknesses of tough sheet-metal, as steel, coated with tin and united by sweating them together. This may be done by inserting several cylinders of slightly varying diameters, one within the other, or rolling a single sheet of metal into volute form, the mode of effecting the junction of the layers being in either case the same; the segmental ends are formed in like manner, and similarly united to the cylindrical body.

Vessels constructed on this principle are used for holding the compressed carbonic-acid gas which serves as a motor for the fish or self-propelling torpedo used in United States naval service.

Fig. 5281.

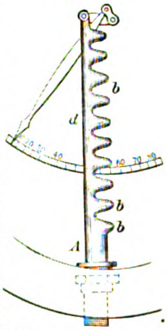


Bottle-Filling Apparatus.

Fig. 5281 is a filling-apparatus.

The bottle *a* has a nozzle *b* communicating with a tube descending nearly to the bottom of the bottle, and has a vertically moving valve, which is depressed either by a thumb-lever or by a knob at top. The apparatus has a tubular standard *c*, at the top of which is an inclined guide *d*, carrying a sliding plate supporting the frame *e*, and raised by depressing a treadle. At the lower part of the frame is a shelf, having an orifice of sufficient size to receive the neck of the bottle. The upper part of the frame has two semicircular arms *g*, one of which is pivoted so as to swing open; the two embrace the bottle, and are secured by a catch; this arm is also provided with a shield to prevent the operator being injured by fragments, should the bottle burst. The bar *d'* holds the socket of the charging-pipe *k*, through which the aërated liquid flows. In charging, the bottle is placed in position in the frame, which is raised by depressing the treadle, bringing the nozzle *b* into a socket on the end of the charging-pipe; by a movement of a lever near *e*, the valve of the bottle is raised, and with the other hand the cock of the pipe *k* is opened, permitting the fluid to flow; when filled, the cock is closed, the interior pressure closing the bottle-valve. See SIPHON-FILLING APPARATUS.

Fig. 5282.



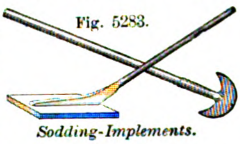
Matthews' Pressure-Gage for Soda-Water Apparatus.

Fig. 5282 is Matthews' pressure-gage for soda-water apparatus (No. 13,468, of 1855). The tube *A* has offsets at one side in the form of hollow plates *b*. By forcing steam or other fluids into the tube, the effect will be to expand or press apart the horizontal portions of the offsets *b*; and thus that side of the tube becomes elongated, producing a deflection of the tube, which (by connection of the upper end of the tube with an indicator) will indicate the pressure. The tube is made by electrotyping upon a core of easily fusible material, such as stearine, which is to be melted when the electrotyping has been finished. This is one of the earliest applications of metal formed by electro-deposition to a strictly mechanical purpose.

Sod-cut'ter. An implement for cutting sods or turfs from the ground. A *paring-plow* or sod-spade.

Sod'ding-im'ple-ments. Tools for cutting sods and laying them down. A sharp bent-handle spade is used for cutting the sods; or, on a large scale, a paring-plow is used.

Fig. 5283.



Sodding-Implements.

In laying down the sods, a curved knife is used, and a flattening mallet for pounding the sods flat.

So'di-um. Equivalent, 23; symbol, *Na* (natrum); specific gravity, 0.972; fusing-point, 190° Fah. This metal was discovered by Sir Humphry Davy in 1807. Sodium is a white metal, oxidizes readily in the air, and rapidly on contact with water. If the water be previously heated, it is decomposed so rapidly and with so much heat as to inflame the hydrogen.

The salts of sodium are widely diffused.

Common salt (chloride of sodium), caustic soda, sulphate of soda (Glauber salts), carbonate of soda, etc., etc., are highly useful in the arts, in glazes, fluxes, medicines, gunpowder, soap, and in preserving meat, as a condiment, etc., etc. See SODA-APPARATUS.

So'di-um A-mal'gam. See AMALGAM, pages 72, 73.

Sod-plow. A plow long in the share and moldboard, adapted to cut and overturn sod.

Sof. A plain cloth made of the hair of the Angora goat.

So'fa. A long, stuffed couch, with seat, back, and ends upholstered.

The couches of the Egyptians, Persians, and Greeks were expensive and handsome. The latter obtained them from their Eastern connections, as indicated by the statement of Athenæus that "Artaxerxes gave Temagoras the Cretan a tent of extraordinary size and beauty, and a couch with silver feet; and he sent him also expensive coverlets and a man to arrange them, saying that the Greeks did not know how to arrange a couch. Plato the philosopher says: 'Men now distinguish the couches and coverings with reference to what is put round the couch and what is put under it.' And his namesake, the comic poet, says: —

'There the well-dressed guests recline
On couches rich, with ivory feet,
And on their purple-cushions dine,
Which rich Sardinian carpets meet.'

For the art of weaving embroidered cloths was in great perfection in his time." — ATHENÆUS (A. D. 220).

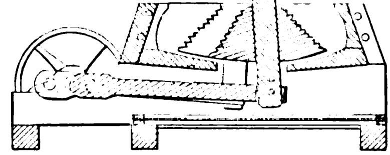
Sof'fit. (*Architecture.*) *a.* The lower surface or *intrados* of an arch.

b. The ceiling of an apartment divided by cross-beams into compartments.

c. The under part of an overhanging cornice or projecting balcony.

Soft'en-ing-ma-chine'. (*Leather.*) A machine of the nature of a fulling-stock, for beating the hides in water to saturate them, as a preliminary to other processes. In that illustrated, the skins, in lieu of simply soaking, are placed in the fulling-mill and water allowed to run into the same. Loose wool is collected by a wire at bottom. The machine is especially employed in the soft or oil treatment of skins of sheep, goats, chamois, deer, etc.

Fig. 5284.



Machine for Softening Sheep-Skins.

Soft Sol'der. An alloy used for soldering.

Tinman's soft solder is usually composed of 2 tin, 1 lead; sometimes, from motives of economy, more lead is used; 1½ tin to 1 lead is the most fusible solder of this kind made without bismuth.

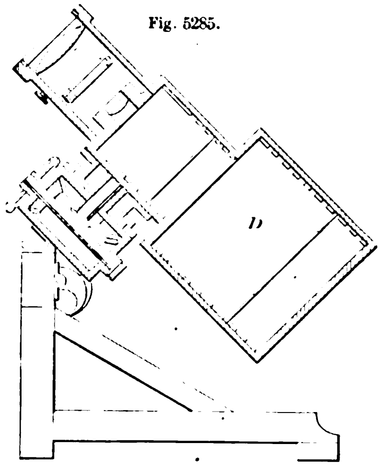
Pewterer's soft solder consists of 2 bismuth, 4 tin, 3 lead; or, 1 bismuth, 1 tin, 1 lead. See pages 62, 63.

Soil-pul'ver-iz'er. (*Husbandry.*) A machine for breaking clods. A form of harrow or flanged roller. See CLOD-CRUSHER, Fig. 1334.

So'lar. (*Architecture.*) A loft or upper chamber of a building. See SOLLAR.

So'lar Cam'e-ra. (*Photography.*) An instrument for enlarging by sunlight. Usually for obtaining an enlarged positive from a negative on glass.

Fig. 5285.



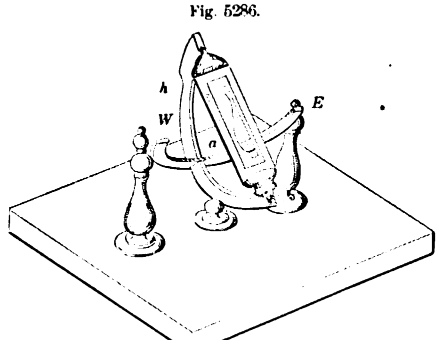
Solar Camera.

The instrument is sometimes used in connection with a heliostat, which keeps the condensing lens directed to the sun. The board to receive the paper for the enlarged picture is placed in such of the grooves in the box *D* as may be adapted to the required enlargement. See also Fig. 3676, page 1681.

So'lar Chro-nom'e-ter. A sun-dial adapted to show mean instead of solar time.

In Fig. 5286, the hour arc *W a E* has the divisions of time engraved upon it, and is set parallel with the equator. To this the arc *h*, which carries the gnomon frame, is centrally fastened, and so that the gnomon is parallel with the earth's axis. The gnomon is a plate perforated by a longitudinal groove, one of whose sides is formed by a curve, the co-ordinates of which are respectively proportional to the sun's declination and to the difference between mean and apparent time for each day, or for successive series of days sufficiently long to render the change in the equation of time graphically appreciable in the scale on which the dial is constructed, so that the shadow cast by the edge of this curve is thrown backward when the sun is fast, and forward when it is slow, to an extent equal to his variation from the mean or clock time, always indicating the mean time upon

Fig. 5286.



Solar Chronometer.

the scale of the equatorial arc. The gnomon must be reversed after each equinox.

So'lar En'gine. An engine in which the heat of the solar rays is concentrated to evaporate water or expand air used as a motor for a steam or air engine.

Archimedes, concentrating the heat rays by mirrors, is said to have set fire to the Roman fleet before Syracuse; however this may be, Buffon, nearly twenty centuries afterward, proved that it was practicable. See BURNING-GLASS.

Professor Mouchat, in France, in 1861, and since, has contrived various apparatus for cooking, distilling, baking, and heating the boilers of engines by solar heat.

Captain John Ericsson has constructed several engines having boilers provided with mechanical devices, contrived by him for effecting the necessary concentration of the solar rays, which he states, when collected from 100 square feet of surface, will effect the evaporation of 489 cubic inches of water per hour,—more than equivalent to one horse-power. This, however, is but a small proportion of the potential energy actually developed by the solar heat hourly received upon this area, which he estimates to be equivalent to that caused by the combustion of 200,000 pounds of coal in the same time.

These experimental engines have cylinders of 2 to 5 inches in diameter, with 6 inches stroke, and have no peculiar constructive novelty; this being confined to the heat-concentrating apparatus.

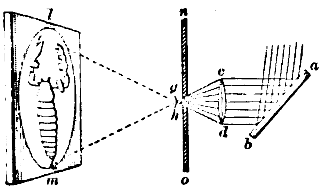
Some are operated by atmospheric air heated to a temperature of 480°, and others by steam of much lower temperature. The speed attained has been in no case less than 100 revolutions per minute, while a regular and continuous rate of 300 revolutions per minute has been reached.

So'lar Eye-piece. Invented by Dawes. An arrangement by which the light and heat are reduced in solar observations by observing only a very minute portion of the solar surface.

So'lar Lamp. Another name for the ARGAND-LAMP (which see). It has a tubular wick and central duct which admit air to the interior of the flame. See page 142.

So'lar Mi'cro-scope. A microscope which throws the magnified image of an object illuminated by the sun's rays upon a wall or screen. A simple form is shown in Fig. 5287. *a b* is a mirror which receives the sun's rays and reflects them through the concentrating lens *c d* upon a transparent object to be magnified. This is placed just within the focus of the magnifying lens *g h*, which throws the image upon the wall or screen *l m*, the size of the magnified figure depending on the distance the instrument is placed from the wall. The room is darkened, usually by a perforated shutter *n o*. This instrument has been now generally superseded by the OXYHYDROGEN MICROSCOPE (which see).

Fig. 5287.



Solar Microscope.

So'lar Tel'e-graph. A telegraph in which the rays of the sun are projected from and upon mirrors. The duration of the rays makes the alphabet, after the system of Morse. It was proposed to apply it to the use of the French army in Algeria, the posts to be established at twenty leagues from each other. See HELIOTROPE.

Sol'der. A metal or alloy used to unite adjacent metallic edges or surfaces. It must be rather more fusible than the metal or metals to be united, and with this object the components and their relative amounts are varied to suit the character of the work.

"Brass is united with brass only by pewter."—LUCRETIUS, Book VI.

Solders are distinguished by specific names, defining quality, composition, or purpose, as *hard, soft, white, spelter, gold, silver, copper, tin, plumber's, pewterer's, button*, etc.

Hard solders are such as require a red heat to fuse them; they are employed for joining brass, iron, and the more refractory metals. Soft solders melt at a comparatively low temperature, and are used with tin and lead, of which metals they are wholly or in part composed. Common tin solder, composed of 1 tin and 2 lead, is perhaps the best-known example of this class. Spelter and silver solders are the most generally used among the hard solders. See ALLOY, page 63.

SOLDERS.

Soft. For lead: tin, 1; lead, 1½. For tin: tin, 1; lead, 2. For pewter: tin, 2; lead, 1.

Hard. For brazing, hardest: copper, 3; zinc, 1. For brazing, hard: tin, 1; copper, 4; zinc, 3. For brazing, softer: tin, 2; antimony, 1.

Gold solder: gold, 1; silver, 2; copper, 3.

Silver solder, hardest: 4 parts fine silver; 1 copper. *Hard:* 3 parts sterling silver; 1 brass wire. *Soft:* 2 parts fine silver; 1 brass wire; ¼ part arsenic is sometimes added at the close of the operation, to make the alloy whiter and more fusible.

Hard brass solder: 8 brass; 1 zinc or tin. *Soft brass solder:* 6 brass; 1 zinc; 1 tin. For iron or steel.

For soldering iron and steel to brass: 3 tin; 39½ copper; 7½ zinc.

White or button solder: 10 parts tin; 6 copper; 4 brass. Also, 10 copper; 8 brass; 12 spelter or zinc.

Fine gold, laminated and cut into shreds, is used for soldering articles, as chemical vessels of platinum, and for gold alloys; silver for soldering German silver; copper in shreds for iron.

The alloy No. 8 in the list, page 62, 2 tin, 1 lead, is used for a variety of metals, as cast-iron and steel, tinware, copper and its alloys, lead and tin pipe, and Britannia ware, an appropriate flux being employed in each case. See list of melting points, ALLOY, page 62.

The fluxes generally employed for soldering, and also for welding, are—

For iron: borax, or sal-ammoniac.
For tinned iron: rosin, or chloride of zinc.
For copper and brass: sal-ammoniac, or chloride of zinc.
For zinc: chloride of zinc.
For lead: tallow, or rosin.
For lead and tin pipe: rosin and sweet-oil.
For pewter: Gallipoli oil (an inferior olive-oil).
For steel: sal-ammoniac, 1 part; borax, 10; pounded together, fused, and pulverized.

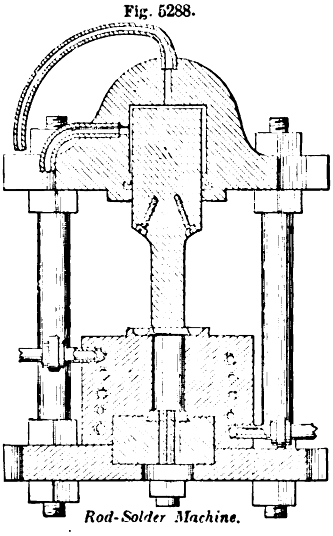
A liquid for use with soft solder is made by dropping small pieces of zinc into 2 fluid ounces of muriatic acid until bubbles cease to rise, and adding ½ teaspoonful of sal-ammoniac and 2 fluid ounces of water to the liquor. See SOLDERING; also page 63, *ante*.

Soft solder is manufactured and sold in the form of ingots, cakes, or rods; the latter are sometimes prepared by forcing the metal in a semi-fluid state through a series of apertures in the bottom of a heated reservoir, in which the metal is poured while fluid, by means of a ram operated by hydraulic power; in other cases the rods are cast in cylindrical radial openings in a wheel, which is caused to rotate beneath the metal reservoir in a manner somewhat analogous to that employed for casting type.

The hard solders are prepared in irregular masses or grains; the finer kinds are drawn into strips or wire.

Sol'der-cast'ing. A mode of making molten solder into sticks or drops for more convenient use.

Fig. 5288.



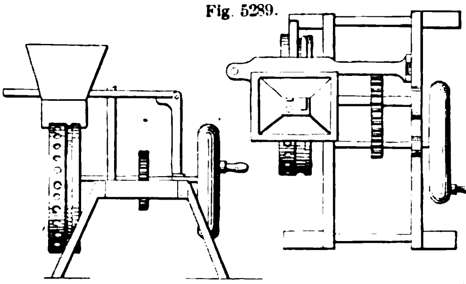
Rod-Solder Machine.

In Fig. 5288, the solder contained within a steam-heated block is expressed therefrom through the perforated bottom by the ram of a hydraulic engine. The die is pierced with numerous holes of the form and size of the rods to be produced.

In Fig. 5289, the reservoir containing the melted metal is hinged by a bar

to a standard on the frame, so as to be elevated when required. The metal passes through an opening in

Fig. 5289.



Drop-Solder Machine.

the floor into the pockets of the periphery of the mold-wheel revolving beneath.

To make spindle-shaped drops, pour the melted solder into cold water at as low a heat as the metal will run. Pour a steady stream ⅛ inch in diameter from a hight of 3 inches above the water.

Sol'der-ing. The process of uniting two pieces of the same or of different metals by the interposition of a metal or alloy, which, by fusion, combines with each. In autogeneous soldering, the two pieces are directly united by the partial fusion of their contacting surfaces, without the intervention of an alloy. See Fig. 738, page 309.

The modes of applying heat are: —
The naked fire.
Hollow furnace or muffle.
Immersion in melted solder.
Melted solder poured on.
Heated iron not tinned.
Heated copper tool tinned.
Blow-pipe flame.
Alcohol flame.
Stream of heated air.

This art was understood and practiced in ancient Egypt. Vases made of imbricated or overlapping plates, and supposed to be soldered together, are represented in tombs of Thothmes III., 1490 B. C. Tin forms an ingredient in soft solder, and was brought from Britain by the Phœnicians 1000 B. C., and probably long before. Malacca also yielded tin in very remote ages.

The pieces which went to form the stand of the silver vase presented to the temple of Delphi by Alyattes, king of Lydia, were of iron inlaid with gold, and were soldered together. This, if it were the second Alyattes, was about 617 B. C. Soldering leaden pipes is mentioned by Vitruvius.

Soldering was apparently unknown in Greece in the time of Homer. Hammered plates, such as armor, were united by mechanical fastenings, — nails, pins, rivets, cramps, and dovetails.

In the ordinary process of soldering small articles, — as, for example, of tinware, — the workman places the two metallic surfaces together, and then, with his *soldering-iron*, which has been previously heated to the proper temperature in a small charcoal furnace beside him, he melts off sufficient solder from the stick or cake, allowing it to flow on, and between the parts to be joined: the hot iron is then applied to the joint, so as to cause the solder to become uniformly fluid, equalize its distribution, and smooth its exposed surface. See also CAN-SOLDERING MACHINE, Fig. 1074, page 452.

Large and heavy pieces of iron and steel are united by interposing sheet copper or brass between the parts to be joined, which have been previously cleansed by filing. They are then fastened together by wire, and the joint is covered with moist clay free from sand; this is allowed to dry, and the pieces are exposed to a blast until they become white-hot and the clay is vitrified; less heat is required for brass than for copper. In soldering iron to iron, the pieces are cooled in water, but in soldering steel to steel they are cooled slowly; brass solder is employed for articles of moderate size, either of iron, steel, or brass. Very fine iron or steel articles are united by pure gold, or hard gold solder, which is also employed for gold. Silver solder is used for silver, and sometimes for German silver. A silver solder, composed of equal parts of silver and malleable brass, is also employed with small iron and steel articles.

For *brazing* or hard soldering, the blacksmith's forge is frequently used, but, in general, a special hearth similar to the forge, but more conveniently arranged for receiving large objects, is used. For large and long works, a flat iron plate standing on four legs having a central aperture for the fuel and provided with tuyeres fed by a fan blower, and having a counterpoised hood suspended from the ceiling, is used. For small works, as articles of jewelry, the blow-pipe is employed, by which the flame of a lamp with a large wick is directed upon the object held upon a charcoal support. The Birmingham cheap jewelry makers employ a gas-jet, and support the object upon a disk of iron covered with a kind of mat composed of fragments of wire and provided with a handle; the blast from a pair of bellows is directed upon the work by a tube.

Great care is taken that the surfaces to be joined shall be perfectly cleaned by filing or scraping: this having been done, they are placed in contact and held, if necessary, by binding wires; the granulated spelter and powdered borax or other proper flux are mixed in a small cup with a very little water and spread upon the joint by a slip of sheet-metal or a spoon. The article is now exposed to the heat, causing first the borax and afterward the solder to fuse and run into the joint, the operation being sometimes assisted by tapping.

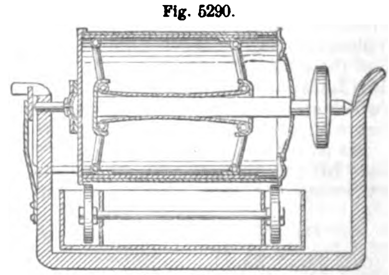
Silver soldering is effected in a very similar way. From its superior fusibility and on account of its not eating or gnawing away the edges of the joints, and, being more sparingly used, requiring less after filing and finishing, it is frequently employed in lieu of the cheaper kinds.

Sol'der-ing-ap'pa-ra'tus. The soldering-apparatus for ordinary work with tin-plate and thin sheet-metals in general comprises soldering-irons (so called) of various sizes, a small portable furnace for heating them, and a box with a spout for holding and applying the rosin or other flux.

The great demand for cans for containing oysters, fruits, and prepared meats has led to the invention of special machines through whose agency the work is greatly expedited.

One of these (Fig. 5290) has collapsible arms which keep the

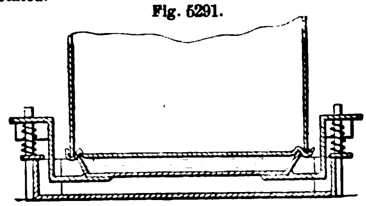
Fig. 5290.



Can-Soldering Apparatus.

body of the can expanded, and hold it while the flux and solder is being applied, automatically or otherwise, when the apparatus is rotated.

Fig. 5291.

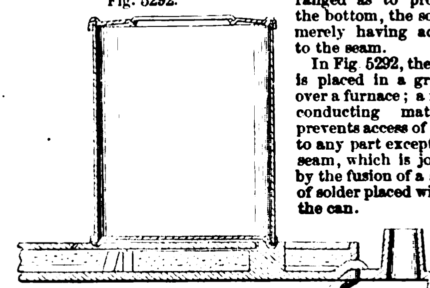


Solder-Pan for Cans.

In another (Fig. 5291), the ends of the can are successively dipped into a bath of molten solder, the support on which the can rests being so arranged as to protect the bottom, the solder merely having access to the seam.

In Fig. 5292, the can is placed in a groove over a furnace; a non-conducting material prevents access of heat to any part except the seam, which is joined by the fusion of a strip of solder placed within the can.

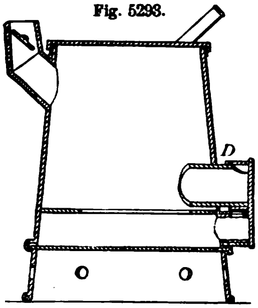
Fig. 5292.



Can-Soldering Apparatus.

Sol'der-ing-fur'nace. A furnace, usually burning charcoal but sometimes having gas-jets, used for heating the soldering-tools used by tinmen, plumbers, etc.

Fig. 5293.

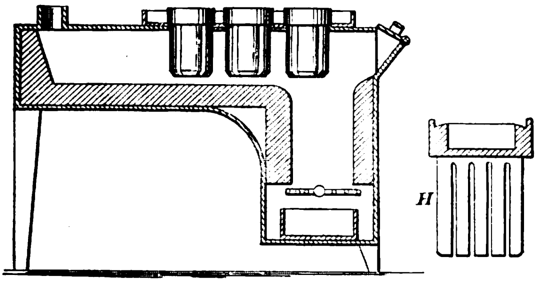


Tinman's Furnace.

Fig. 5293 has a cover *D* inclosing the tube through which the iron is presented to the fire, and which extends sufficiently far inward to prevent the fire acting directly upon the front casing of the furnace. Another furnace (patent No. 49,517) has a soldering-tool passing through the fire and projecting on each side, in order that the work may be held up to it and moved along against the iron.

Fig. 5294 is a furnace having pans on top for heating the ends of cans for soldering. The pans have a slight rim, which is of metal, and a central depression which is filled with gypsum or some other non-conducting substance, in order that the heat may

Fig. 5294.

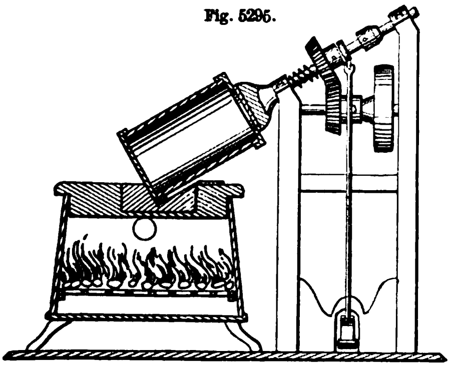


Soldering-Furnace.

affect no part but the rim. The pans have plates *H* (see small figure) extending down into the fire to conduct the heat to the pans.

In Fig. 5295, the can is attached to the end of a shaft, which

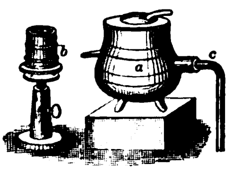
Fig. 5295.



Soldering Tin Cans.

during its rotation causes each part of the seam to dip successively into the solder-bath.

Fig. 5296.



Pewterer's Hot-Blast.

A peculiar modification of the blow-pipe is employed by pewterers. It consists of a common iron pot *a* having a close-fitting cover and apertures on each side through which the blast-pipe *c* passes; this is technically called the *hod;* it is partially filled with ignited charcoal, so as to heat the blast of air which passes through the pipe *c*. The work is supported on a revolving pedestal *b*, termed the *gentleman*, which may be adjusted by a side-screw to any desired hight; a strip of solder is dipped in oil and applied to the joint with the right hand while the work is slowly revolved by the left.

It has been proposed to apply the term *galvanic soldering* to the uniting of two pieces of metal by the deposit formed between them when submitted to electro-magnetic influence in the sulphate bath. This method would seem too tedious and expensive to be of very general application.

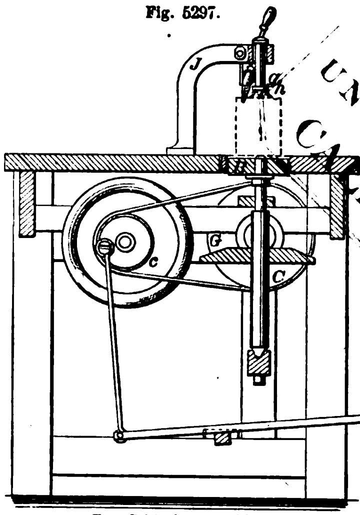
Sol'der-ing-ir'on. The tool whereby solder is melted and applied in the ordinary method of working. It is, however, a block of copper, called a *copper-bit*, on the end of an iron rod provided with a wooden handle. See SOLDERING-TOOL.

Sol'der-ing-lamp. An alcohol or oil lamp with a thick wick, adapted for the dentist and jeweler. The peculiar burner known as the *Bunsen burner* is much used. The gas is mixed with atmospheric air before inflaming, and the result is a hot, blue, smokeless flame. See STOVE-BURNER.

Sol'der-ing-ma-chine'. One for holding cans while being soldered or applying the soldering-tool to them while rotating.

In Fig. 5297, the can rests on a rotating table *B* turned by a treadle *H* operating the band-wheels *C c* and bevel gears *G*, and is held by a spring plunger *g* with spurs *h*; the soldering-iron

Fig. 5297.

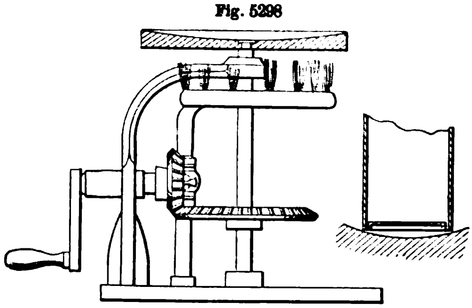


Can-Soldering Machine.

is supported in a rest on the arm *J* and is applied to each part of the seam as the can rotates.

Fig. 5298 has a gas-heated shallow metallic solder-pan. The boxes are placed, one at a time, upon the pan, with their lower

Fig. 5298



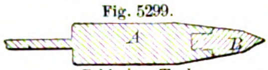
Soldering-Stand.

edges immersed in the solder thereon; the operation is completed by holding them there an instant and then removing them. See CAN-SOLDERING MACHINE, Fig. 1074, page 452.

Sol'der-ing-tool. The soldering-tool, generally termed a *soldering-iron*, used by tinmen and other workers in thin sheet-metals, consists of a copper *bit* or *bolt* having a pointed or wedge-shaped end, fastened to an iron rod with a wooden handle. It is *tinned* previous to being used by heating to a dull red, hastily filing off the scale, so as to produce a clean metallic surface, and then rubbing, first upon a lump of sal-ammoniac and next upon a copper or tin plate on which a few drops of solder have been placed, and afterward wiped clean with tow. Various improved forms have been contrived.

In Fig. 5299, the body *A* is made of cast-iron and has a dovetail mortise at the end, into which a tenon on the copper point *B* is expanded by driving. Another has a copper point cast on to the iron body.

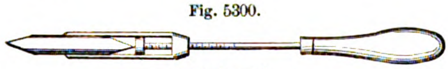
Fig. 5299.



Soldering-Tool.

In another (Fig. 5300), the bit is reversible, and may be protruded any desired distance beyond the socket in which it is held, the rod to which the handle is attached being screw-threaded and working through the socket.

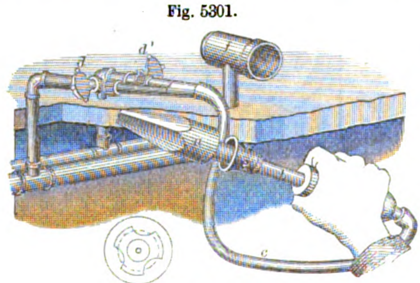
Fig. 5300.



Soldering-Bit.

In Sears' (Fig. 5301), the copper tip *a* is hollow at the base and receives the hollow handle *b*, which is screwed therein, and is connected by a flexible pipe *c* with a nozzle through which two pipes provided with cocks *d d'* project respectively air and gas. The gas is first let on, and as it escapes at the base of *a* is lighted, and the air-supply cock being then opened, a flame is maintained at the aperture in the handle *b*, near the end of the tip *a*, at the point where the greatest heat is required, its intensity being regulated by means of the cocks *d d'*. A shield *e* on the handle serves to deflect the heat back on the tip *a* and protect the hand of the operator. When not in use, the tip is inserted in the hollow rest *f*.

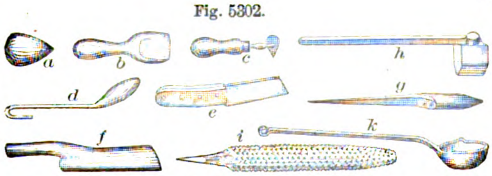
Fig. 5301.



Soldering-Tool.

Fig. 5302 shows the tools commonly used by plumbers for soldering and fitting pipes and joints.

Fig. 5302.



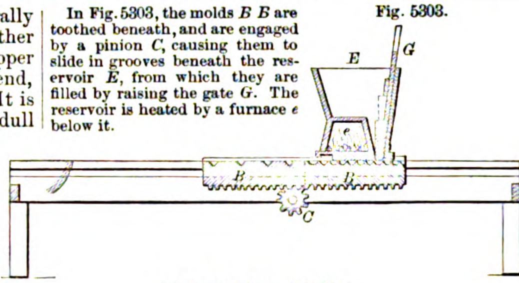
Plumbing and Soldering Tools.

a, turn-pin.	*f*, dresser.
b, side edge.	*g*, copper bolt.
c, shave-hook.	*h*, copper hatchet.
d, round iron.	*i*, rasp.
e, chipping-knife.	*k*, ladle.

Sol'der-mold. A device for casting solder into rods or pellets of convenient form for use.

In Fig. 5303, the molds *B B* are toothed beneath, and are engaged by a pinion *C*, causing them to slide in grooves beneath the reservoir *E*, from which they are filled by raising the gate *G*. The reservoir is heated by a furnace *e* below it.

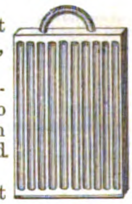
Fig. 5303.



Molding Tinners' Solder.

A mold in which solder is cast into bars. Fig. 5304 is simply a plate having a series of grooves and provided with a loop or handle at one end for lifting and turning out the bars when cool enough. See also SOLDER-CASTING.

Fig. 5304.



Solder-Mold.

Sole. The bottom or bearing part of an object, as a crane, wheel-felly, gun-carriage, plane, rudder, etc.

Sole and *sill* occupy, generally speaking, the same relation to any object to which they are attached or to which they refer, and the words are derived from the same verbal root.

1. (*Shoemaking.*) The bottom part of a boot or shoe.

2. (*Agriculture.*) *a.* The lower part of the plow which runs in contact with the bottom of the furrow. It is generally only the lower surfaces of the *share* and *landside*.

b. The bottom of the furrow.

3. (*Vehicle.*) A strip of metal or wood fastened beneath the runner of a sled or sleigh to take the wear.

It is made of hard wood for farm-sleds, dry sugar-tree or red beech being excellent.

Bob-sleds are shod with an amalgam cast-iron (so called).

Sleighs are soled with band iron or steel.

4. (*Machinery.*) *a.* The top or floor of a bracket on which a plummer-block rests. See BRACKET.

b. The plate which constitutes the foundation of a marine steam-engine, and which is bolted to the keelsons.

5. (*Hydraulics.*) The lower edge of the barrel of a turbine or water-wheel.

6. (*Mining.*) *a.* The seat or bottom of a passage in a mine. The floor of a gallery.

b. The bottom frame of a wagon.

7. (*Fortification.*) The bottom of an embrasure. The *sill* is the inside edge of the *sole*.

8. (*Metallurgy.*) The floor or hearth of the metal-chamber in a *reverberatory*, *puddling*, or *boiling* furnace.

9. (*Shipbuilding.*) *a.* The bottom plank of the cradle, resting on the bilgeways, and sustaining the lower ends of the poppets, which are mortised into the sole and support the vessel.

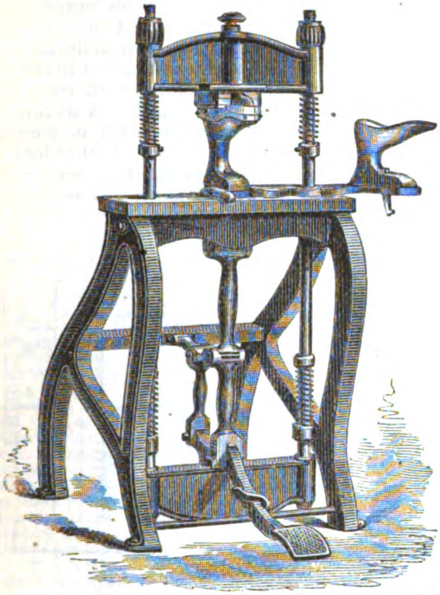
b. An additional piece on the lower end of a rudder, to make it level with the false keel.

10. (*Joinery.*) The lower surface of a plane.

Sole-beat'ing Ma-chine'. (*Shoemaking.*) A machine for finishing boots and shoes, — pressing the sole and laying the channel. The swinging bed has two forms, in order that a shoe may remain under pressure upon one while the operator is placing another shoe upon the second. The pressure is given by the treadle, which brings down the upper platen upon the channeled sole.

Sole-chan'nel-ing Ma-chine'. A machine for cutting a groove in the sole of a shoe in which the

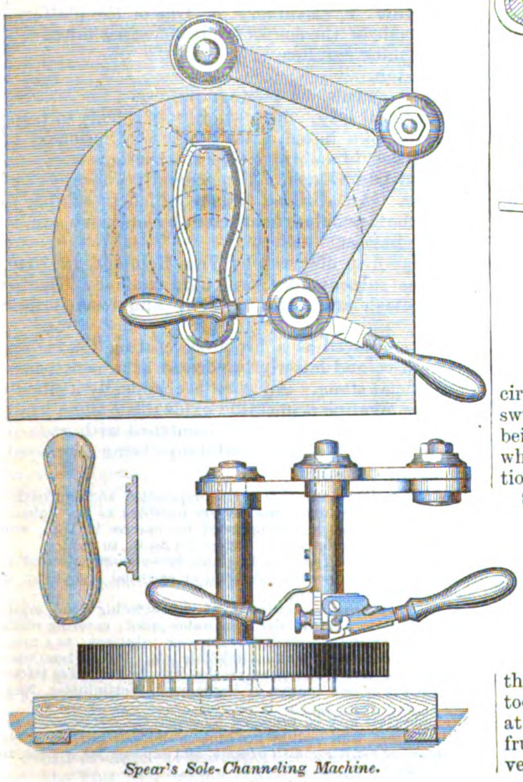
Fig. 5305.



Beating-out Machine (Shoe-Machinery Manufacturing Co.).

sewing-stitch may lie and be protected. In Spear's machine, the sole being fastened to the turn-table, the tool to be used for channeling or beveling is

Fig. 5306.



Spear's Sole-Channeling Machine.

slipped into the end of the jointed arm, which arm holds the tool in a perpendicular position. Then the operation of channeling or beveling is performed by drawing the tool around the sole, using the edge of the sole as a guide to determine the cut of the knife or knives, the shoulder on the tool resting against the edge of the sole as the tool is forced along, turning the table as is necessary.

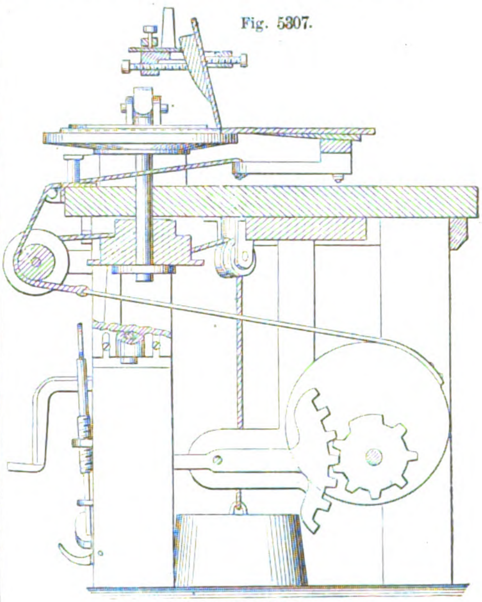
Sole-cut′ting Ma-chine′. One in which sole-shaped pieces are cut from the side or from strips of leather.

The ordinary hand-cutters have dies the shape of the sole, driven by a mallet. Or a sheet-metal pattern is laid on the leather, and its edge followed by a knife.

In machines, several plans are adopted. One has a vertically moving sole-shaped die, which is brought down upon the leather fed upon a table beneath. Or a roller has projecting blades shaped alternately like the respective sides of the sole. The strip is passed along the bed, beneath the roller, and issues as soles and waste scraps.

Another sole-cutting machine is one in which the leather and the metallic pattern are clamped to a

Fig. 5307.

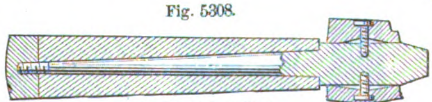


Sole-Cutting Machine.

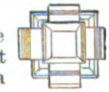
circular revolving table. The knife is supported on swivelled arms and follows the edge of the pattern, being actuated by a cam and a toothed foot-lever, which also raises a weight to perform the return motion. See also SOLE-ROUNDING MACHINE.

Sole-fin′ish-ing Tool. A burnishing-tool for

Fig. 5308.



Sole-Finishing Tool.

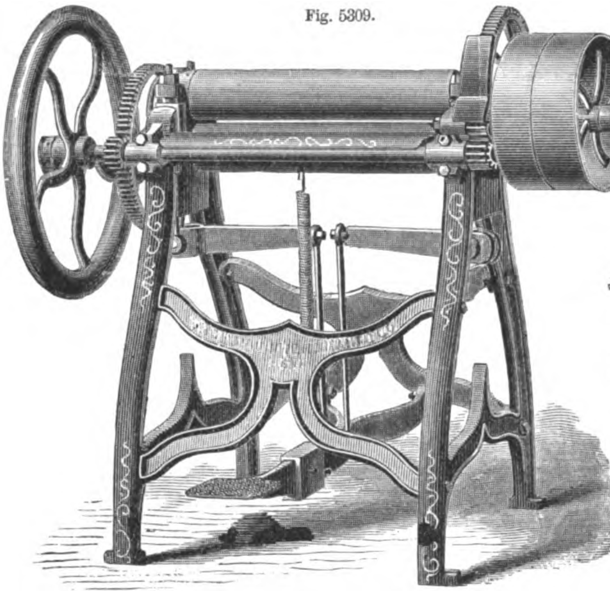


the edges of soles. In the example, the tool-head is a four-sided prism, except at its guide, where it approximates to a frustum of a four-sided pyramid. A reversible edge-block is applied to each face of the

head revolving thereon, and has finishing ends of different sizes and shapes. The edge-block is connected with the head by adjustable clamp-screws. See also EDGE-TOOL, page 773.

Sole-leath′er Roll′ing-ma-chine′. A machine to compact and consolidate leather, either in the side or strip or after being cut out and shaped. The pressure of the rolls is regulated by the treadle and intermediate levers.

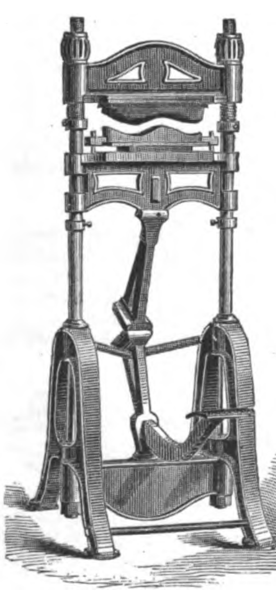
Fig. 5309.



Sole-Leather Rolling-Machine.

Sole-mold′ing Ma-chine′. (*Shoemaking.*) The operation of this machine comes before the parts are assembled upon the last. The sole is molded by it to fit the bottom of the style of last which is in use. The lower platen is forced against the upper by the treadle and toggles, and is retracted by springs.

Fig. 5310.



Sole-Molding Machine.

So′len. (*Surgical.*) *a.* A cradle for a broken limb.

b. A tent or tilt of splits or wands to hold the bed-clothes from contact with a broken or sore limb.

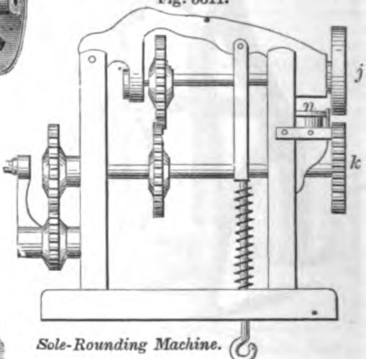
Sole-plate. 1. (*Steam.*) The *foundation-plate* or *bed-plate* of an engine. See SOLE.

2. (*Hydraulic Engineering.*) The back portion of a water-wheel bucket. It is frequently formed by a continuous inner cylinder concentric with the axis of the wheel, and upon it the buckets are built.

Sole-round′ing Ma-chine′. A machine for giving the curved contour to strips of leather designed for soles. The pattern is attached to the top of the blank, and kept in contact with the guide while the feed-rollers *j k* are turned, and the blank is cut to form by the knife attached to the block *n*.

Sole-shap′er. See SOLE-MOLDING MACHINE.

Fig. 5311.



Sole-Rounding Machine.

Sole-tree. (*Mining.*) A piece of wood belonging to a small windlass to draw up ore from the mine.

Sol′id New′el. (*Joinery.*) A post into which the ends of winding stairs are built. A *hollow newel* winds around a well-staircase.

Sol′lar. 1. (*Mining.*) *a.* One of the platforms at the ends of the successive ladders in a mine.

b. A mine entrance.

2. A loft.

So′lo-graph. A photograph.

Sol′u-bil′i-ty. Susceptibility of a body to being dissolved in a liquid. See Storer's "Dictionary of Solubilities," Cambridge (Mass.), 1864.

Sol′u-ble Glass. Also generally known as *water-glass.* An alkaline silicate which is soluble in water, but remains unaffected by ordinary atmospheric changes.

It was first observed by Von Helmont, in 1640, and was subsequently, in 1648, made by Glauber from potash and silica, and by him termed fluid silica.

It is employed as a fire-proof coating for various substances, and latterly important as a constituent of artificial stone. All glass is chemically a silicate of some alkaline or metallic oxide; but those kinds alone in which the silica is combined with soda or potash without a third substance being employed, are soluble in water.

For much that is valuable in the preparation and application of water-glass or soluble glass, we are indebted to Dr. Johann Fuchs, of Munich. He announced his success in 1825, and published a pamphlet shortly before his death, in 1856.

Mr. Ransome, of Ipswich, England, has also contributed to the success of the process. It forms an essential ingredient of Ransome's artificial stone.

It has been used in painting on glass; surfacing stone, wood, and other materials to render them water-proof; covering roofs, for the same purpose; glazing scenery or paintings; as a menstruum for carbon, in making indelible ink. It has been used to arrest the wear of the stone, on the Cathedral of Notre Dame, Paris, and the new houses of Parliament, Westminster, England.

Soluble glass may be prepared by either the *wet* or *dry* way. In the former, flint nodules are broken and calcined, added to a solution of caustic potash or soda, and exposed for a time to intense heat.

In the dry way the constituents are fused together in the solid state, and afterward dissolved. Four kinds are employed, known as the *potash*, *soda*, *double*, and *clear* silicates. The first is composed of 15 parts pulverized quartz, 10 purified potash, 1 pulverized charcoal. These are well mixed, and exposed to a strong heat in a glass-melting pot until thoroughly fused. When cool, the mass is broken in pieces, and boiled for about 3 hours in 5 times its weight of water, more water being occasionally added to replace that lost by evaporation. When thoroughly dissolved, it is viscid, and may be used in this state or still farther diluted. It should be preserved in well-stopped vessels.

The soda silicate is composed of 45 parts pure quartz, 23 anhydrous carbonate of soda, and 3 pulverized charcoal; these are fused and treated in the manner just described. By substituting the anhydrous sulphate for the carbonate of soda and using about 8 times more charcoal, a cheaper compound is produced. Buchner's formula for soda water-glass is, pulverized quartz, 100; calcined glauber salts, 60; carbon, 15 to 20 parts. The double silicate is composed of 100 parts quartz, 28 purified potash, 22 neutral anhydrous carbonate of soda, and 6 powdered charcoal. This mixture fuses more easily than either of the others. In its place three parts of the first and two of the second solutions, which mix freely together, may be employed

The mixed silicate forms with sand an excellent cement, converting it into a stone-like mass, and is also useful for filling cracks in walls. Marble dust, or chalk made into a paste with water, dried and saturated with the silicate, forms a mass little inferior in hardness to marble, and capable of taking a fine polish. A mixture of marble dust and the silicate of soda forms a cement which adheres either to stone or wood. Oxide of zinc combines with the silicate, forming a paste, which may be rolled into sheets resembling slate.

The *clear* silicate is applied for fixing the colors of pictures. It is made by fusing 3 parts pure anhydrous carbonate of soda with 2 of powdered quartz, the compound being boiled as before. This is kept in a concentrated solution, and for use 1 part is mixed with 4 parts of the concentrated potash silicate completely saturated with quartz.

The *fixing* water-glass of Von Fuchs is used for fixing the colors in stereochromy, and is composed of silica well saturated with potash, water-glass, and a silicate of soda, obtained by melting together 3 parts calcined soda and 2 of pulverized quartz.

The prepared water-glass of commerce is made by boiling the powdered water-glass in water, forming solutions known as of 33° and 66° respectively, those amounts denoting the respective amounts by weight of solid water-glass contained in 100 parts of the solution.

Wall paintings are fixed by water-glass in a much more durable manner than ordinary frescoing. The ground may be similar to that employed for frescos, or a water-glass mortar may be employed, composed of about 10 parts dry sharp sand, 3 quicklime, and 2 dry pulverized chalk or limestone, worked to the proper consistency with dilute water-glass. Water-colors, not too heavily laid on, are applied, care being taken to reject organic colors, which are fugitive, and such others as have a tendency to combine with the glass. When the picture is finished, the whole is fixed by an application of the water-glass in thin jets from a rose nozzle syringe. The process has received the name of *stereochromy*.

Water-glass is also used as a vehicle for painting upon glass, various metallic oxides and salts being employed as the coloring mediums, the compound becoming chemically united with the silicious surface of the glass, so as to resist the action of water.

It also is made up into a paint or cement with clay, whiting, chalk, calcined bones, powdered glass, or litharge in various combinations. It makes a very strong and adhesive compound.

The theater of Munich, Bavaria, was painted with a composition in which 10 per cent of yellow clay was added to soluble glass.

Dobereiner's formula gives a soluble glass suitable for coating woodwork:

Carbonate of potash	70
Carbonate of soda	54
Ground flints or quartzose sand	152
	276

Another formula given is: —

Carbonate of soda (or carbonate of potash, 10)	8 parts.
Pure sand	15 parts.
Charcoal	1 part.
	24 parts.

The product dissolves in boiling water.

The addition of hydrochloric acid causes the silica to separate as a transparent, tremulous jelly. This is hydrate of silica, is not soluble in water or acids, may be preserved in a gelatinous condition, but crumbles when dried.

Som'er-set. (*Saddlery.*) A saddle padded before the knee and behind the thigh; originally made for Lord Fitzroy Somerset, who had lost his leg below the knee at the battle of Waterloo, and from whom it takes its name.

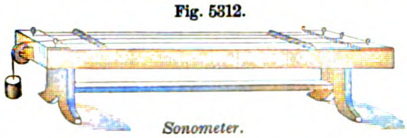
Son'i-fer. An acoustic instrument for collecting sound and conveying it to the ear of a partially deaf person. It is an instrument of metal, of a bell shape, and is placed upon a table with its mouth in the direction whence the sound proceeds; the volume of sound is collected in the bottom of the instrument, and conducted by a flexible pipe to the ear.

Son-nette'. (*Music.*) A *clapper* or *castanet* having a movable tongue, which strikes the stick and forms a clinking accompaniment to music or the dance.

A bell used in a band as a tinkling accompaniment.

So-nom'e-ter. An instrument devised by Marloye for determining the number of vibrations made by a string emitting any musical sound. It is provided with a series of weights, to vary the tension of the central string, the others being tuned by pegs, and has three divided scales, one corresponding to the modified chromatic gamut, another to the true chromatic gamut, and the third the French meter divided to thousandths.

Fig. 5312.



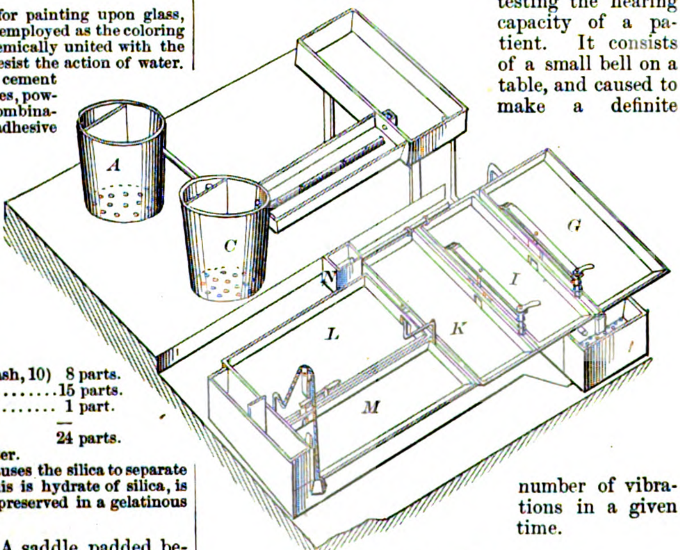
Sonometer.

The following table gives the notes, the number of their vibrations, and the duration of their residual sensations. (The French notation, used by König, is adopted.)

Note.	No. of Vibrations per Second.	Duration of Residual Sensation of the Sound.
C_1	64	$^1/_{16}$ second
C_2	128	$^1/_{26}$ "
C_3	256	$^1/_{47}$ "
G_3	384	$^1/_{60}$ "
C_4	512	$^1/_{75}$ "
E_4	640	$^1/_{95}$ "
G_4	768	$^1/_{109}$ "
C_5	1,024	$^1/_{135}$ "

2. A device for testing the hearing capacity of a patient. It consists of a small bell on a table, and caused to make a definite number of vibrations in a given time.

Fig. 5313.



Arrangement of Sugar Filters and Pans.

Soo′cey. (*Fabric.*) An Indian mixed striped fabric of cotton and silk.

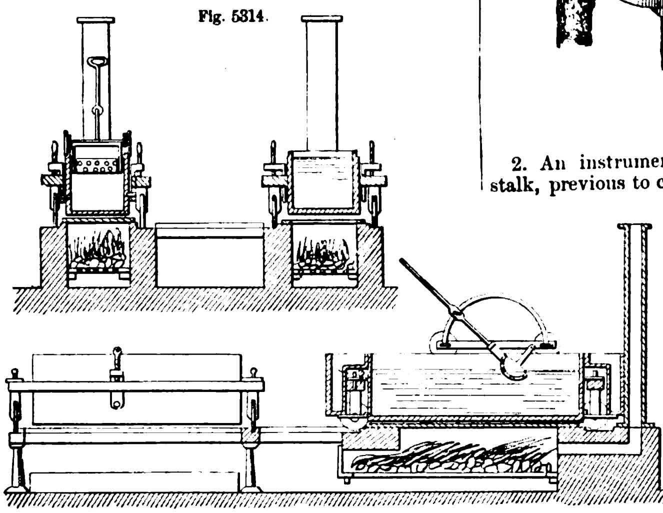
Sor′dine. (*Music.*) A little implement placed on the bridge of a stringed instrument, in order to deaden the sonorousness and give it a mournful sound. A *mute.* See Plate LXI., Bonanni's "Istromenti Armonici," Roma, 1776.

Sor′ghum-e-vap′o-ra-tor. A furnace with pans for boiling the expressed juice of the sorghum or imphee.

Fig. 5313 shows an apparatus consisting of a series of filters and pans. The juice is first purified in the filters *A C*, passes to settling-troughs, is conducted by pipes to the pan *G*, where it is brought to a boil, passed through a hot filter, and thence to pans *I K L M* in succession, by which it is condensed.

Figs. 1888, 1889, 1890, pages 812, 813, show evaporators with pans in succession and in steps; also a rocking-pan with a sinuous track for the juice.

Fig. 5314.

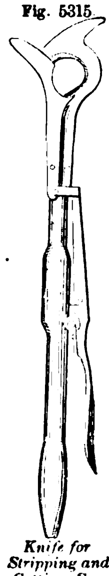


Sorghum-Evaporator.

Fig. 5314 shows an arrangement of pans on carriages by which they may be brought into the required position or succession over the furnaces. Each evaporating-pan is pivoted to a truck, by which it may be moved along tracks from one furnace to another, or from the place of filling to that of deposit. The supporting casters may be turned 90° to allow of running over all portions of the rectangular track. The pans may be tilted to discharge their contents.

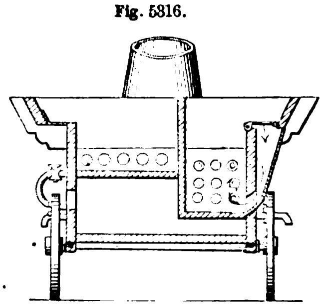
In Fig. 5316, an outside filtering pocket is filled with wool; as the juice boils over, it cools and sinks in this pocket, and reaches the pan again, parting with the scum and feculencies which are retained by the wool. This keeps up a continued circulation and straining process.

Fig. 5315.



Knife for Stripping and Cutting Sorghum.

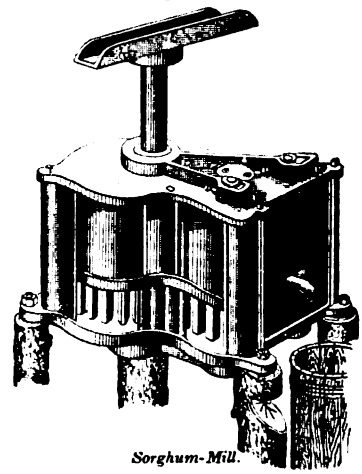
Fig. 5316.



Pan and Self-Skimming Arrangement.

Sor′ghum-knife. 1. A sword or machete for cutting sorghum-stalks.

Fig. 5317.



Sorghum-Mill.

2. An instrument for stripping leaves from the stalk, previous to crushing.

Fig. 5315 combines the two. The movable jaw is opened and the stalk gripped; a motion downward strips off the leaves, and a draw motion cuts the stalk at the ground.

Sor′ghum-mill. A machine for grinding the stalks of the *sorghum* (*Holcus* or *Sorghum saccharatum*) or imphee. One variety is also known as the Chinese sugar-cane. The imphee is probably African. There are many varieties. It is closely allied to the *dourra* and the broom-corn.

The cane is pressed between vertical rollers, and the juice is collected in the bed-plate, which has a ridge around it, and is thence discharged into tub, bucket, or cistern. See also CANE-MILL; SUGAR-MILL.

The use of the "Turkish" and the "American corn" stalks for yielding a saccharine juice was recommended in an English magazine of April 1, 1800. The former appears to have been a *sorghum* or *imphee*, as the brushy top was farther recommended for brooms. The author also recommends the American green corn, "*split into quarters and fried in batter like young artichokes.*" Cob and all it should seem!!

The subject of the use of maize-stalks for yielding molasses is considered in the Agricultural Reports of the Patent Office, about 1846; see also M'Culloch's Report on Sugar and Hydrometers, 1846.

Sor′ghum-strip′per. (*Husbandry.*) A knife for stripping the blades from cane-stalks. See CANE-KNIFE, page 444; SORGHUM-KNIFE.

Sor-ren′to-work. Fret carving, done by a jig-saw. As a lady's employment, it is rather a miniature form of the usual productions of the scroll or fret saw. Brackets, card-cases, and the more delicate articles of household adornment are thus made, the effect being much enhanced by carving.

Sort. (*Printing.*) Any letter, figure, point, space, or quadrat belonging to the compositor's case.

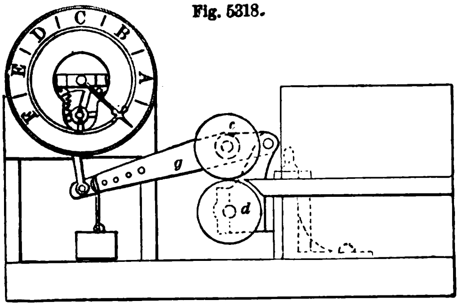
Out of sorts means that some are exhausted.

To *run upon sorts* is with work which requires an unusual number of certain kinds; as an *index*, which requires a disproportionate number of capitals, or a tabular statement in figures, which makes a run upon the figures, etc.

Sort′ing-ma-chine′. Fig. 5318 is a machine for gaging leather strips as they are cut from the

hide to certain regulated sizes. The strips pass between two rollers *c d*, the lower one of which turns in fixed bearings, and the upper is journaled in a lever *g*, which operates a rack and a pinion carrying

Fig. 5318.



Leather-Sorting Machine.
